George Cutter, 333 The Rookery, Chicago, has got out a very handsome little design for back of small postal card, telling about the improved Schaefer incandescent lamp. It is only another of Mr. Cutter's clever little advertising schemes, and, like the rest of them, is right "up to date."

T. A. Pamprin, president of the Electric Manufacturing Co., of Oconto, Wis., manufacturers of the "Brilliant" incandescent lamp, spent several days in Chicago during last week.

T. C. Rafferty, secretary of the Great Western Electric Supply Co., Chicago, left this week on a flying business trip through Texas and Louisiana.

Mr. S. J. Bear, of Topeka, Kan., has been elected supreme chancellor of the telegrapher's organization, at the recent Kansas City meeting.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

THE
Electrical Engineer.

VOL. XIV. SEPTEMBER 28, 1892. No. 230.

THE GENESIS OF THE MODERN DYNAMO: ANTONIO PACINOTTI.—II.

BY

Franklin Leonard Pope

MORE than twenty-five years after his original work Dr. Pacinotti presented a detailed statement concerning the history of his discoveries to the jury of the International Electrical Exposition at Turin, in 1884. This statement is a document of surpassing interest, and conclusively establishes the claim of its author to the credit of the invention of the modern system of armature winding and commutation, if not to the further honor of a discovery which so eminent an authority as the late Clerk-Maxwell once asserted, and justly so, to be the most important one that had been made in twenty-five years—the reversibility of the dynamo machine. The paper bears date September 24, 1884.

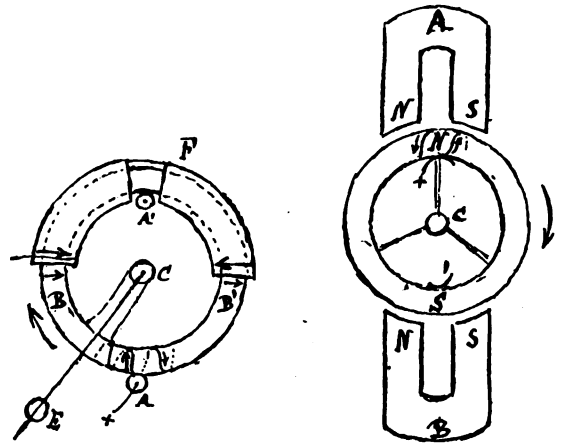
The earliest conception in the mind of Dr. Pacinotti of the ideas which afterwards led in logical sequence to the construction of the machine on which his title as a discoverer rests, appears to be contained in a manuscript notebook which has been preserved by him, in which, under the date of 1858, is found the following entry:

> Perhaps the use in magnetic machines of the induced current in lieu of currents obtained directly from the battery might be found useful.

This passage embodies a distinct conception of the idea of the reversibility of the magneto-electric machine; but the further conception of the closed armature winding, or, as Pacinotti usually terms it, the "transverse connection" follows almost immediately in another entry in the same book, in which is clearly outlined the suggestion of making use, in an apparatus for measuring electrical currents, of an annular helix composed of a single layer of wire with transverse connections (Fig. 6). The following is a translation of this memorandum:

> The instrument consists of a light ring B B' wound helically with a copper wire whose turns might be insulated as in the rheostat, without the wire being covered with silk.[1] The two ends of the wire are soldered together and the helix is closed. This circular helix is placed in a vertical plane, is centered at C, and counter-weighted so that its equilibrium may be indifferent. The helix described is surrounded by another stationary helix, F, which forms a semicircle. The circular helix rests upon two brass rollers A A^1, one of which A is at the middle of the stationary helix, the other being at the extremity of the diametrical line. The current goes through the stationary helix, thence passes through the movable circular helix by means of the brass rollers A A'. Supposing that A be in connection with the positive pole, A' with the negative, the current divides into two portions at the point A, and as is readily understood, the portion that goes through the part B goes from the circumference to the centre on the front side of the helix, while that which goes through the part B' goes from the centre to the circumference. Supposing the current to go through the stationary helix as indicated by the arrows, the half B of the movable circular helix is attracted, while the half B' is repelled, which compels the movable helix to rotate in the direction indicated by the arrow.
>
> A pendulum E is raised by the motion; this is prolonged in such way as to prevent the deviation from exceeding a right angle; the force of the current is proportional to the sine of the angle of rotation. * * * * The induction current, which during the motion is generated in the contrary direction to the current that produces it, does not exist any more when the motion ceases and does not therefore affect the readings.

It does not appear, however, that Pacinotti ever attempted to reduce this apparatus to practice in the form above suggested, doubtless for the reason that the conception of applying the same principle of construction to the armature of an electromagnetic motor, or, as he calls it, a "magnetic machine," appears to have struck his mind almost immediately, for on the very next page of the same note-book the matter is set forth explicitly in the following sketch and description. (See Fig. 7.)



FIGS. 6 AND 7.

> *Electromagnetic machine without interruption of circuit.*
>
> The wheel C has a ring of iron on which is wound a helix whose turns are insulated as on the wooden cylinder of the rheostat. At N and S are the rollers or springs which touch the successive coils of the helix; from what we have previously said the ring of soft iron will be magnetized transversely; let us suppose the current to be directed in such a way that the north pole is at N, and the south pole at S; if two horseshoe magnets A, B are placed in proximity, as indicated in the figure, the wheel ought to turn in the direction indicated by the arrow. It is easy to see from the arrangement that the induced currents will be able to set a limit to the speed of the wheel but will not be able to produce sparks.

In the last sentence will be noted an expression which goes to show that the author was not unfamiliar with the reaction which we now call "counter-electromotive force."

---

[1] The reader is reminded that the term rheostat was then applied exclusively to the now obsolete form consisting of two cylinders, one of wood, the other of metal, geared together so as to wind or unwind from the wooden cylinder a bare wire, the space between the turns being depended on for insulation.—[TRANSLATOR.]

In his written notes, Pacinotti goes on to set forth a method of applying a plurality of layers of conducting wire to the ring armature. This, though afterwards superseded by more practical designs, deserves mention as illustrative of the gradual evolution of ideas in the mind of the young inventor:

> *Construction of the closed helices; continuous induced currents.* * * *
>
> In the circular magnet electromagnetic machine there is developed an induction current contrary in direction to that of the battery. If the current of the battery is no longer sent through the ring, but the latter is turned by power in front of two permanent or temporary magnets, there will be a current induced continually, directed in the same direction. One could consequently make use of such an apparatus for obtaining an induction current directed always in the same direction, just as one might make use of devices adapted to show the rotation of a finite current produced by a circular current.[2]
>
> In constructing the circular helix which is necessary in the electromagnet machine as also in the induction apparatus,[3] I would propose the following plan for enabling more helices to be put on:
>
> Taking the ring, either of iron or of other substance, there will be wound over it a rather thin well-insulated copper wire in case it is desired to make the apparatus for producing the induction current, and a very thin copper strip in case it is desired to construct an electromagnetic machine. At every three or four turns there should be left a loop of the wire or the strip, and after going entirely around the ring the two ends should be soldered together. On top of this first spiral, there can be put another, perfectly similar, but wound in the contrary direction, then another in the same direction as the first, etc. Let us suppose that there are two helices; on the ring we will place a circle of some isolating substance and in this at one portion we will imbed a number of small metal pieces[4] each one of which may connect with the corresponding end of the first helix; on the other portion those that connect with the second, (see Fig. 8). If at the end A we put one end of the first helix in connection with one pole and that of the second helix in connection with the other pole, and at the opposite side B the ends of the two helices are connected together, the current goes through both halves of the ring in the same direction in the two helices, as is necessary.

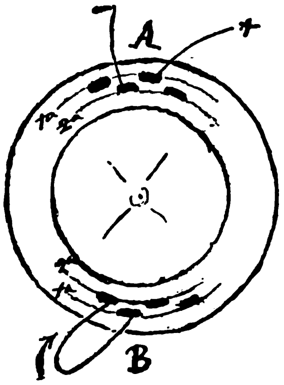


FIG. 8.

Following up the ideas which had suggested themselves to his mind, as shown by the extracts which have been quoted from the note-book of 1858, Pacinotti entered upon a systematic course of experimentation. Providing himself with a ring of round bar iron, he wrapped it for better insulation with a coating of silk, and then wound upon it an endless helix of copper wire of moderate thickness which he insulated with silk and varnish. This helix constituted but a single layer of wire, and its ends were soldered together. A disc of wood was tightly fitted into the interior of the ring after having been thus wound, and the whole was mounted upon a rotatable axis, which was made to pass through its centre. Two contact springs of brass were mounted upon fixed supports, so as to bear respectively against diametrically opposite points on the external periphery of the ring coil. The insulating coating was then removed from each turn of the helix, at the point where, in passing, it would touch one or the other of the two contact springs. The contact springs themselves were connected with the opposite terminals of a galvanometer. Two permanently magnetic steel bars were also provided, which could be supported in various positions with reference to the ring, in such manner that their poles would be in close proximity to its periphery during its rotation.

Under date of January 10, 1859, the following entries appeared in the note-book, referring to experiments made with this apparatus:

> A north pole placed at one extremity of the diameter normal to that which joins the springs, gives a strong deflection when the wheel is turned. After a little time, the needle oscillated very near to 30 degrees; on reversing the direction of the rotation, the direction of the current was also reversed.
>
> On placing another north pole at the other extremity of this normal diameter, the needle oscillated near zero. On placing a south pole instead, at that extremity, the needle resumed oscillating near 30 degrees. The direction of the deflection was the same as with the single north pole; and it was reversed with the direction of rotation.

After making some preliminary experiments with the ring described above, Pacinotti commenced the construction of a somewhat larger one, covered in the same manner with a silk wrapping, and then closely wound with a helix of silk insulated copper wire. Loops were left for forming the connections in the manner referred to in the note quoted above. Only one such helix, however, was made, for the idea had now occurred to the experimenter that the ring might with greater advantage be wound with a number of equidistant consecutive helices, each having a plurality of layers, and that these helices might be connected with each other, and with the corresponding contact upon the commutator, by means of intervening loops left during the progress of the winding. A subsequent experiment, made with a second ring wound in this manner, enabled Pacinotti to observe that when the current from a battery was made to pass between two loops of the helix an actual magnetization of the iron ring took place, the points of opposite magnetic polarity being situated directly underneath the respective points of entrance of the opposite electricities into the helix.

Pacinotti had progressed thus far with his experiments, when his work was suddenly interrupted by the call for volunteers in the war for Italian independence. He responded promptly to the summons of his country, and it was while serving in the field during the campaign of 1859, that another conception of no small importance came to his mind. He relates that he was sitting one evening on the ground upon the heights of Goito, when the radial arrangement of the stacked muskets near at hand chanced to catch his eye, and associating themselves with the constant object of his thoughts, the magnetic machine, gave rise to the suggestion that the inductive influence of the stationary field magnets upon the rotating ring might be enhanced by enlarging, or by forming radial projections upon the iron ring or core of the armature in the intervals which had been left between the helices, a conception which, as we have seen, was embodied in the actual machine which he afterwards constructed.

INDUCTO-SCRIPT.

AT the recent meeting of the British Association, the inducto-scripts of the Rev. F. J. Smith, of Glasgow, were shown and explained by the recorder, Mr. Baynes. A coin or engraved metal is placed on a photographic plate and the induction spark passed from the coin to the metal; on developing an image like the breath-figures appears, not, however, if the experiment is made *in vacuo*. Mr. Glazebrook, F. R. S., has tried moistened bromide plates without or with the external current of one cell; he obtained similar, but rather irregular results.

---

2. This comparison is obscure. The original text gives no clue to what devices are referred to.—[TRANSLATOR.]

3. Literally "apparatus for induction," the term by which Pacinotti first designated his electric machine when acting as a generator or dynamo.—[TRANSLATOR.]

4. This first set of commutator segments is designated in the diagram by the figures 1^a (*prima*). The second set is designed by the figures 2^a.—[TRANSLATOR.]

THE MOUNT WASHINGTON SEARCH LIGHT.

BY

A. C. Shaw.

THE top of a mountain 6,300 feet above sea level seems at first sight a curious location at which to install an electric search light, and it will be admitted that few men would ever have conceived the idea of making the experiment. To Mr. L. H. Rogers must be attributed the honor of first suggesting that a search light would be an attraction on the top of Mount Washington, and that it could be operated successfully. Mount Washington, as is well known, is the highest mountain in the States east of the Rockies and north of the Carolinas, and belongs to the White Mountain range in New Hampshire. Large numbers of people visit these mountains every summer, and beautiful little towns and large hotels nestle in the surrounding valleys, most of them being situated where a good view of the king of the mountains may be had. Access to the mountains is extremely easy, the Concord and Montreal Railroad from Boston being the most popular route, as the line runs through country abounding in fine scenery, and takes the traveler to the very base of the mountain where the Mount Washington Railroad begins. Besides affording a vast amount of interest and amusement to the mountain summer visitor, the search light, poised at this extreme elevation, is of great scientific interest, and as much has already appeared in the daily press, an illustrated description of the plant will doubtless be found interesting. Results have been achieved which have never before been thought possible, and many new problems in the study of search lights for signaling and other scientific purposes are attracting the attention of the scientific world. Before describing further the effects of the search light in penetrating the darkness of the rarefied atmosphere at the altitude of 6,300 feet, a description of the plant itself will be found interesting, as it is, perhaps, the highest mountain electric plant—other than mining—in the United States, and has to overcome obstacles not met with in lower levels.

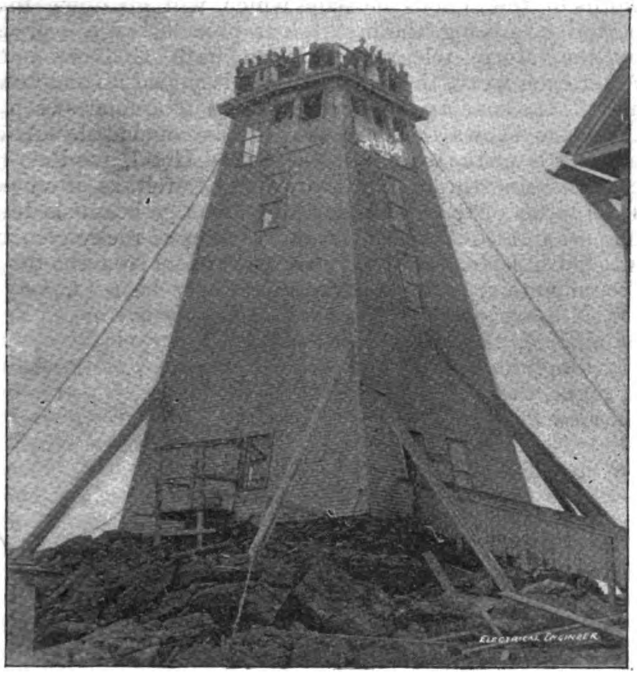

FIG. 1.—TOWER OF THE MOUNT WASHINGTON SEARCH LIGHT.

A tower has been erected on the very highest point of the mountain, a view of which is shown on this page, occupying the site of the old rough open tower used formerly by the Geodetic and Coast Survey. The tower, Fig. 1, is 27 feet square at the base, 50 feet high, and tapers to 14 feet square at the top. It is built of eight 9-inch spruce timbers reaching from the foundation to the top, each of the floors being supported on similar timbers, and the whole tied together by iron straps and bolted, and the frame work chained down to the rocks on the mountain top. The whole building was then covered by heavy planking and clapboarded on the outside, but even with this protection, so severe are the wind and rain storms, the moisture penetrates the building and makes the condition of operating a dynamo extremely severe, the armature after a severe storm being frequently saturated with moisture. The first floor of the tower contains engine, boiler, dynamo and switchboard, the whole steam plant having been furnished by J. A. Grant & Co., of Boston. It consists at present of a 30 h. p. vertical tubular boiler, manufactured by the Erie City Iron Works, of Erie, Pa., which works at a pressure of 80 pounds. The engine will eventually be a 25 h. p. McIntosh & Seymour high-pressure engine, as it is expected that current will be furnished for lighting the Summit Hotel; but at present a 15 h. p. Armington & Sims engine is used. Rainwater is used for the boiler, and it is fed through a National heater by means of a small Worthington pump, which lifts the water from a tank 10 feet below. In dry weather the water is brought up in tanks by one of the Mount Washington Railroad locomotives filled from the watering tanks on the side of the mountain. The dynamo is of the Thomson-Houston spherical armature type, compounded and capable of giving 75 volts and 110 amperes. In spite of the severe conditions owing to the extreme dampness, it has given every satisfaction, and has run without a hitch from the first. The switchboard is of the skeleton type, made of wood, and contains ammeter, voltmeter, a double-pole single-throw 120 ampere switch for the main search light circuit and two 10 ampere switches for the 18 incandescent lights distributed on the different floors of the tower. These lamps are on two circuits, one for the upper floors and one for the engine-room. Fuse blocks and lightning arresters are also mounted on the switchboard so as to prevent any chance of accident. In the engine-room and protruding through the floor may be seen the top of the highest point of the mountain, and the picture, Fig. 2, shows in the centre of the room a red incandescent lamp burning in a vase filled with water, which serves to mark the position of the copper bolt inserted in the

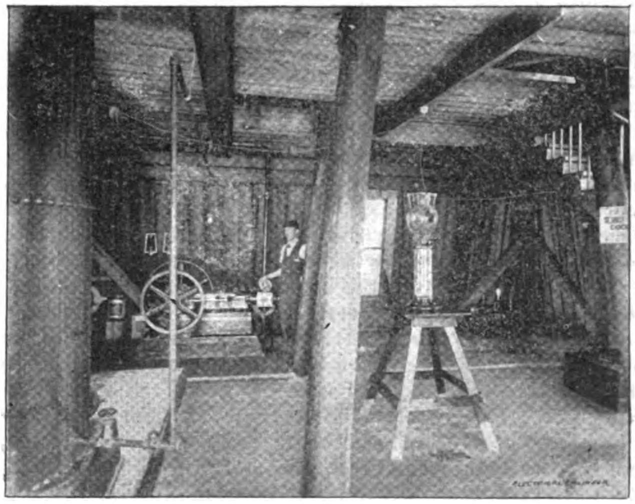

FIG. 2.—DYNAMO ROOM, MOUNT WASHINGTON SEARCH LIGHT.

rock, which formed one of the station marks set by the Geodetic and Coast Survey during their operations, now completed. The second and third floors of the tower are used as storerooms, the fourth as the lower observation-room, and the fifth as the general observation and controlling-room. In this room is the controlling stand shown in Fig. 3, on which is mounted a standard Weston voltmeter and ammeter, resistance coils and various switches for operating the light and the motor in the base of the search light by which the projector can be turned round in any direction, and the elevation altered at will. On the roof of the tower, open to the atmosphere, is situated the search light, Fig. 4, which was manufactured by the General Electric Co. The light is enclosed in a projector of 30 inches diameter, the largest ever made in America, and is of 100,000 c. p., nom., the actual candle power of the lamp without the reflector being 20,000. Hardtmuth carbons, made specially for this work in Vienna, Austria, are used in the lamp, measuring 1¼ inches diameter for the positive, and 1 inch for the negative, the positive carbon being cored. The reflector consists of a Mangin lens with 14 $\frac{15}{16}$ inch focal point made in Paris by a secret process, by which the quicksilver on the back of the reflector can withstand the extreme heat of the arc. The lamp when operating requires 45 volts and about 90 amperes, the voltage of the dynamo being reduced by resistances on the floor below. A full description of the details of the lamp may be found in the ENGINEER of Aug. 24 in Mr. Knowles's excellent article on "The Modern Electric Search Light," so that it is not necessary in this article to describe the lamp in detail, but rather to point out a few of the interesting results.

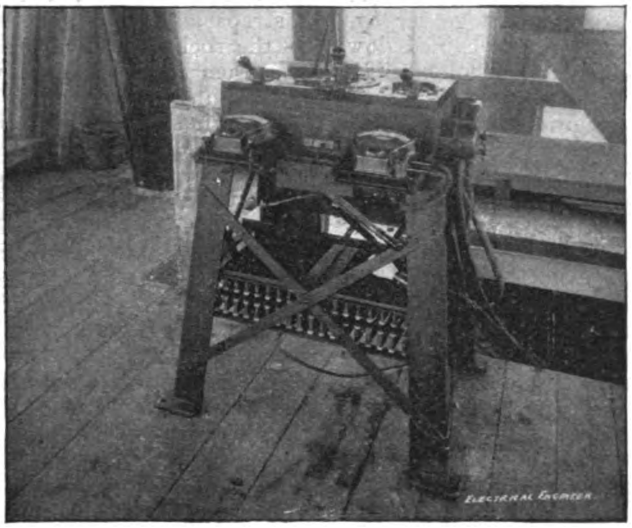

FIG. 3.—CONTROLLING STAND FOR THE SEARCH LIGHT.

Viewed from any of the well-known summer resorts in the vicinity the effect is very fine, and it is astonishing to note the interest shown in the light by the visitors to these hotels, who gather in knots on the verandas and discuss the all-absorbing topic of "search lights" and endeavor to read the messages signaled to them, by means of a code which has been distributed in thousands all over that section of the country. At Maplewood, for instance, where the writer recently stood on one beautiful clear night 20 miles from the top of the mountain by air line, the light was "turned on" the hotel for about 20 minutes, and signals were read with the greatest ease and precision. At that distance the light is almost too bright to be looked at comfortably, and the effect of the illumination on the hotel is quite marked. The time on a watch is easily told and type as large as the heading of this article read with ease. On white surfaces such as the front of the hotel a curious shimmering effect is produced, and small dark patches seem to float constantly over the surface, produced perhaps by the magnified effect of minute particles of vapor in the atmosphere, or by some other phenomenon not yet accounted for. The signaling is accomplished by a metal damper in the inside of the projector which can be lowered between the arc and the lens by a lever extending to the outside, and by means of which flashes of short or long duration can be effected. At Maplewood, on the night when the writer was present, several signals were given and readily interpreted. Before spelling out the words, ten short flashes were given to attract attention; and then came a series of long and short flashes, spelling out the words of the famous message which will go down to all posterity as being the first telegraphic message ever sent by the Morse telegraph: "What hath God wrought." After each word, the beam of light is moved up and down, and at the conclusion of the sentence a circular sweep of the beam shows that the message is concluded. A few minutes later the words: "Maplewood Hotel, good night," came flashing through the air, and one felt as if on personal terms of friendship with the friendly beam shedding its pure light over the intervening miles of rocky glen and wooded hillside. At Fabyan's, eight miles from the top of the mountain, ordinary type can easily be read, and at Mr. Milliken's Glen House, which is only five miles away by air line, the light makes the grounds as light as day. Standing alongside of the projector on the top of the tower at night, the sight is also a very grand one, and a beautiful view of the beam of light can be had. When the projector is turned in the direction of any of the portions of the mountain from one-half to one mile away, the effect is very pretty, as it makes a round circle of light, and shows up any particular object even more distinctly than by daylight. It is a great source of pleasure to the visitors and they never seem to tire of watching the different effects produced. That it is a great attraction in the mountains is amply proven by the fact that in small places where the lights of the village cannot be seen by the naked eye from the mountain top, large bonfires are nightly kindled in the hopes that the ray of light will be turned in their direction. Many letters and telegrams are also received daily with "special requests for the search light," and letters from many emiment men within a radius of 100 miles have

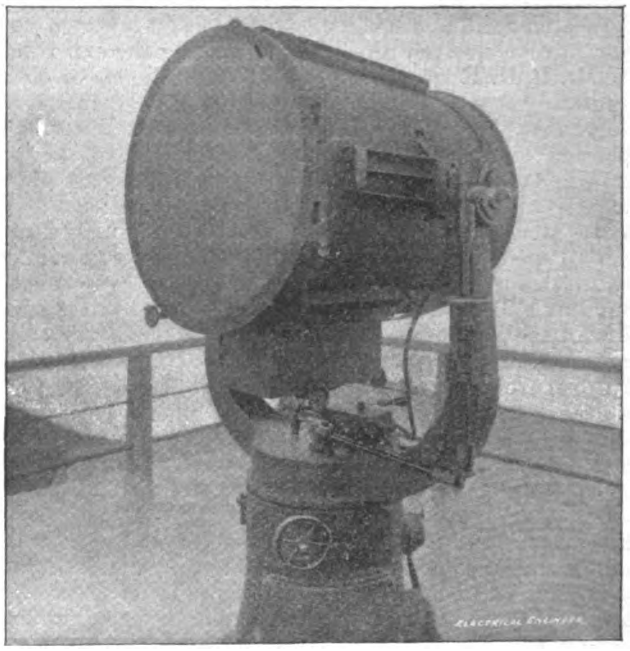

FIG. 4.—THE PROJECTOR ON MOUNT WASHINGTON.

been received stating that the light had been seen and asking for further experiments in their particular directions.

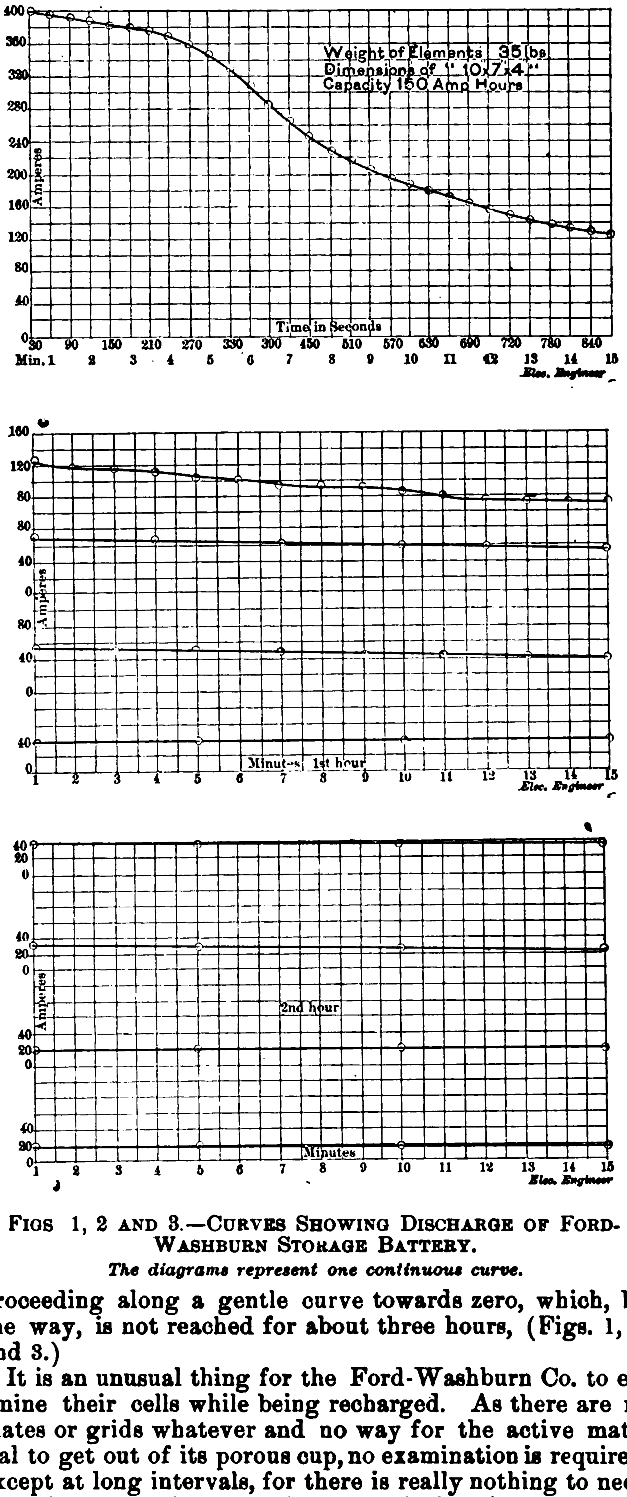
As to the distance from which the light has been seen it is a little difficult to get accurate figures. At Portland, which is 85 miles away, the beam of light has been distinctly seen, and actual telegraphic conversation held with the operator on the mountain, the search light flashing out a message, and the telegraphic operator at Portland repeating it by ordinary telegraph back to the mountain. Many towns 100 miles away have reported seeing it, and one report states that it was seen on one occasion at Pigeon Cove, Cape Ann, on the coast of Massachusetts, a distance of 116 miles. Recently the New England district of the Weather Bureau has instructed Mr. Rogers to make experiments on weather signaling, and for the past three weeks weather signals have been shown at eight o'clock every evening to the surrounding districts, a combination of long and short flashes signifying fine or rainy weather according to the reports from the Bureau. These signals have been seen and read at Exeter, N. H., a town about 100 miles from Mount Washington, and are giving general satisfaction to the surrounding countryside.

It is just about a year since the idea first occurred to Mr. Rogers to put a search light on top of Mount Washington, and great credit is due him for his persistent effort in the face of all adverse criticism and general unbelief in its practicability. The raising of the necessary funds was also a difficulty to overcome, but eventually Mr. Rogers was enabled to raise sufficient subscriptions, to partly pay for the plant, from the railways in the vicinity and from the hotel proprietors, who were slowly led to believe in the value of the search light as a mountain attraction. Mr. T. A. McKinnon, of the Concord and Montreal Railroad, was one of the first to favor the scheme, and rendered all the assistance in his power. Mr. Payson Tucker, of the Maine Central, also added his support to the project, and now nearly all the hotels in the mountains are subscribers. The operating expenses of the plant are all taken care of by Mr. Rogers, who has made a contract with the subscribers to keep the plant in running condition for a period of five years, and expects to refund himself by making a nominal charge of 25 cents admission to the tower.

Mr. Mark Lowd and Mr. Frank C. Sargent are in charge of the plant, and are kept busy showing the interesting features to the numerous visitors, and pointing out the various places of interest from the top of the tower. The light was started on August 13, and will be stopped for the season on October 1, but next season it will be reinstalled at the same place, and from its commanding position amongst the clouds, its piercing rays will without doubt once more light up the mountain tops and penetrate for miles through the surrounding atmosphere to thousands of watchful people in the valleys below, who have come to look upon it as an actual friend and a part of their summer entertainment.

THE FORD-WASHBURN STORAGE BATTERY CAR.

An interesting and impressive test of the storage battery car of the Ford-Washburn Storelectro Co., of Cleveland, Ohio, took place last Thursday in Cleveland. There were on the car a number of gentlemen, capitalists, electricians and others, among whom were Mr. Leopold Wallach, of New York; Chas. W. Kohlsaat, of New York; Messrs. Geo. A. Ford, L. A. Cobb, Geo. A. Washburn and Geo. Hoyt, of Cleveland, and Mr. F. R. Colvin, of The Electrical Engineer. Col. F. K. Hain, General Manager of the Manhattan Elevated Railroad Co., was also to have been present, but telegraphed he would be detained in New York a few days longer and would therefore not be able to inspect the car until the following week. An early start was made with the car over the tracks of the principal street railway companies of Cleveland. There was not a hitch of any kind in the trip. The passengers, after having viewed the beauties of Euclid avenue and compared the behavior of the car with that of its trolley companions before and behind it, proceeded to the works of the company to witness a few simple tests of the battery itself. Those who had not before seen it were surprised at the short-circuiting test in which a cell was connected with heavy copper strips direct to an ammeter of negligible resistance; the instrument showed 400 amperes at the moment of contact, slowly falling to 350 amperes in the course of a few minutes and then gradually and steadily proceeding along a gentle curve towards zero, which, by the way, is not reached for about three hours, (Figs. 1, 2, and 3.)



Figs 1, 2 and 3.—Curves Showing Discharge of Ford-Washburn Storage Battery.

The diagrams represent one continuous curve.

It is an unusual thing for the Ford-Washburn Co. to examine their cells while being recharged. As there are no plates or grids whatever and no way for the active material to get out of its porous cup, no examination is required, except at long intervals, for there is really nothing to need attention or repairs. As the rate of charging can be 25 amperes or higher without any injury to the battery, the company justly claims another point of superiority. It intreested and delighted the electricians present to see Mr. Washburn pick up stray short bits of copper wire of various sizes and attach them across terminals of any cell he happened to be near without the least concern for the welfare of the cell; the wire would simply smoke, sizzle and burn off. A comparison was then made between the elements of the Ford-Washburn battery and the broken-down and broken-up grids of other storage batteries of the old type of manufacture which had been subjected to the same treatment.

The elements of the Ford-Washburn battery, which had been in use for nearly a year, were as good as new, while the grids of its companion cells were in various stages of fracture and disintegration.

Before the party left, the Ford-Washburn Co. was put in possession of an order for several thousand cells, which will necessitate an immediate and considerable increase of facilities. It is the intention of the company to open a branch office in New York City at the earliest possible moment, where a good-sized battery of its storage cells will be permanently on exhibition. It is not unlikely, also, that after the car has been exhibited at the coming Street Railway Convention in Cleveland it will be seen running in the streets of New York. As the trolley is as yet unknown in the heart of New York City, the car will, perhaps, not create the comment bestowed upon it in Cleveland on the day of the test, when a little street urchin shouted, with some perturbation: "Mister, your trolley is broke!"

THE PHYSICS OF THE VOLTAIC ARC.[1]

THIS paper by Prof. S. P. Thompson, F. R. S., refers to recent work which he has carried out in conjunction with Mr. Eustace Thomas and Mr. Portheim. The potential difference of the steady arc is about 40 volts. Part of this is constant, independent of the current and the length of the arc. This constant part, 35 to 39 volts, has also been called the back electromotive force of the arc, and its seat has been found by Prof. Thompson to be at the crater. The great absorption of energy there might be due to the volatilization of carbon; the light intensity at the crater is indeed a constant, according to Captain Abney. Quite recently, however, Mr. Crookes has observed that the flaming discharges produced at high alternations and high voltage are endothermic flames of nitrogen and oxygen, that is, they absorb heat. Prof. Thompson, therefore, surrounded the arc with a glass tube into which various gases were introduced; the back electromotive force was not altered; the possible combination of nitrogen and oxygen; has, therefore, nothing to do with the electromotive forces observed. Small variations may, however, be due to endothermic actions. The gases have, of course, to enter in a gentle current, as any blowing raises the voltage very much (up to 75 volts in air), and the nature of the gas affects the crater. With carbonic acid and chlorine the crater and the negative cone flatten out. Hydrocarbons deposit soot all round; in oxygen, both carbons burn away very fast.

PHOTOGRAPHS OF ELECTRICAL DISCHARGES.[2]

MR. CAMPBELL SWINTON lets the sparks of a Wimshurst machine strike a gelatino-bromide plate which is simply placed between the electrodes. Negative sparks are like graceful palm leaves and feathery; positive less regular, and more ramified like rootlets. Alternate discharges from a Tesla coil show both figures superposed. Mr. J. Brown, of Belfast, who exhibited some beautiful spark photographs at the Bath meeting, ascribed them to an electrographic or electro-chemical, and not to ordinary light action. Mr. Swinton seems to have disproved this. He covered his plates partly with mica and ebonite; the obaque ebonite prevented the effect, the transparent mica did not. The character of the film has no influence. The plates are covered with metal foil at the back.

STRONG'S VERTICAL TRIPLE-EXPANSION ENGINE.

THE engine shown in the accompanying illustrations has been designed to meet the demand for a compact machine suitable for driving dynamos, and for other purposes where it is desirable to economize space, to secure economy in fuel, and to utilize the higher ranges of expansion, either as a condensing or non-condensing engine. There are many places where it is not practicable to use a condenser on account of the scarcity of condensing water, and as it is possible to secure about the same economy with very high steam pressure without condensation this engine has been designed to fulfil that end. It has been the aim of the designer, Mr. Geo. S. Strong, the well-known mechanical engineer, of this city, to put a triple-expansion engine into the simplest and most compact form, and at the same time to meet all the requirements that are considered necessary for general efficiency and economy.

A peculiarity of the design is that the engine is self-contained and balanced. The reciprocating parts of the two sides have simultaneous opposite movements, the cranks being 180 degrees apart, and thus, in a manner, balancing each other. In consequenee of this, and the fact that each side is independently balanced by a counter-weight on the crank, less foundation is required and more quiet running is produced than would otherwise be the case. This is very important in buildings where jarring from engines is very annoying. If it is desired that the engine shall be absolutely noiseless it can be placed upon a foundation insulated on the bottom by cork from the foundations of the building, while on the sides packing or other material can be used that will not transmit noise or vibrations to the walls.

To meet the requirements of an engine using steam of 180 to 200 lbs. pressure, piston valves have been selected for the high and intermediate cylinders and gridiron slide valves for the low pressure cylinders. By this means frictionless valves for the high and intermediate cylinders, where the pressure is high, are secured. In those cylinders the matter of clearance is comparatively unimportant. In the low pressure cylinders, however, small clearances are very necessary for economy and are brought about by the use of the gridiron valves in the cylinder heads.

The high and intermediate cylinders are double acting, while the low pressure cylinders are single acting with trunk pistons, which act as cross-heads for the engine. The piston rods extending up through from the low pressure cylinders, carry the two pistons, one of the high and the other of the intermediate cylinders. The steam is admitted to the high-pressure cylinders by a central piston valve, located in the same valve chamber, and between the two piston valves that exhaust the steam from the high-pressure cylinder, on to the piston of the intermediate cylinder. This first valve admits steam to the high-pressure cylinders, and cuts it off according to the requirements of the engine to maintain a uniform speed, but does not exhaust it, the exhaust being controlled by the end valves, as described.

The movement to this central valve is transmitted through the solid valve stem, which works through the hollow valve stem that operates the two end valves. This solid valve stem is worked from the link block, which block is controlled by the governor, while the hollow valve stem that controls the movement of the end valves, receives its motion from the pin in the end of the link, and has a constant travel.

The two end valves exhaust the steam from the two ends of the intermediate cylinder into the passages which lead to the gridiron slide valves that admit the steam into the low-pressure cylinders and it is exhausted from the low-pressure cylinders through the gridiron valves situated on the outside and in this same casting which forms the heads of the high and intermediate, and also the heads of the low. Thus all the valves are in the one casting that joins the high and intermediate cylinders. This casting is finished entirely by boring, as all the valves are intro-

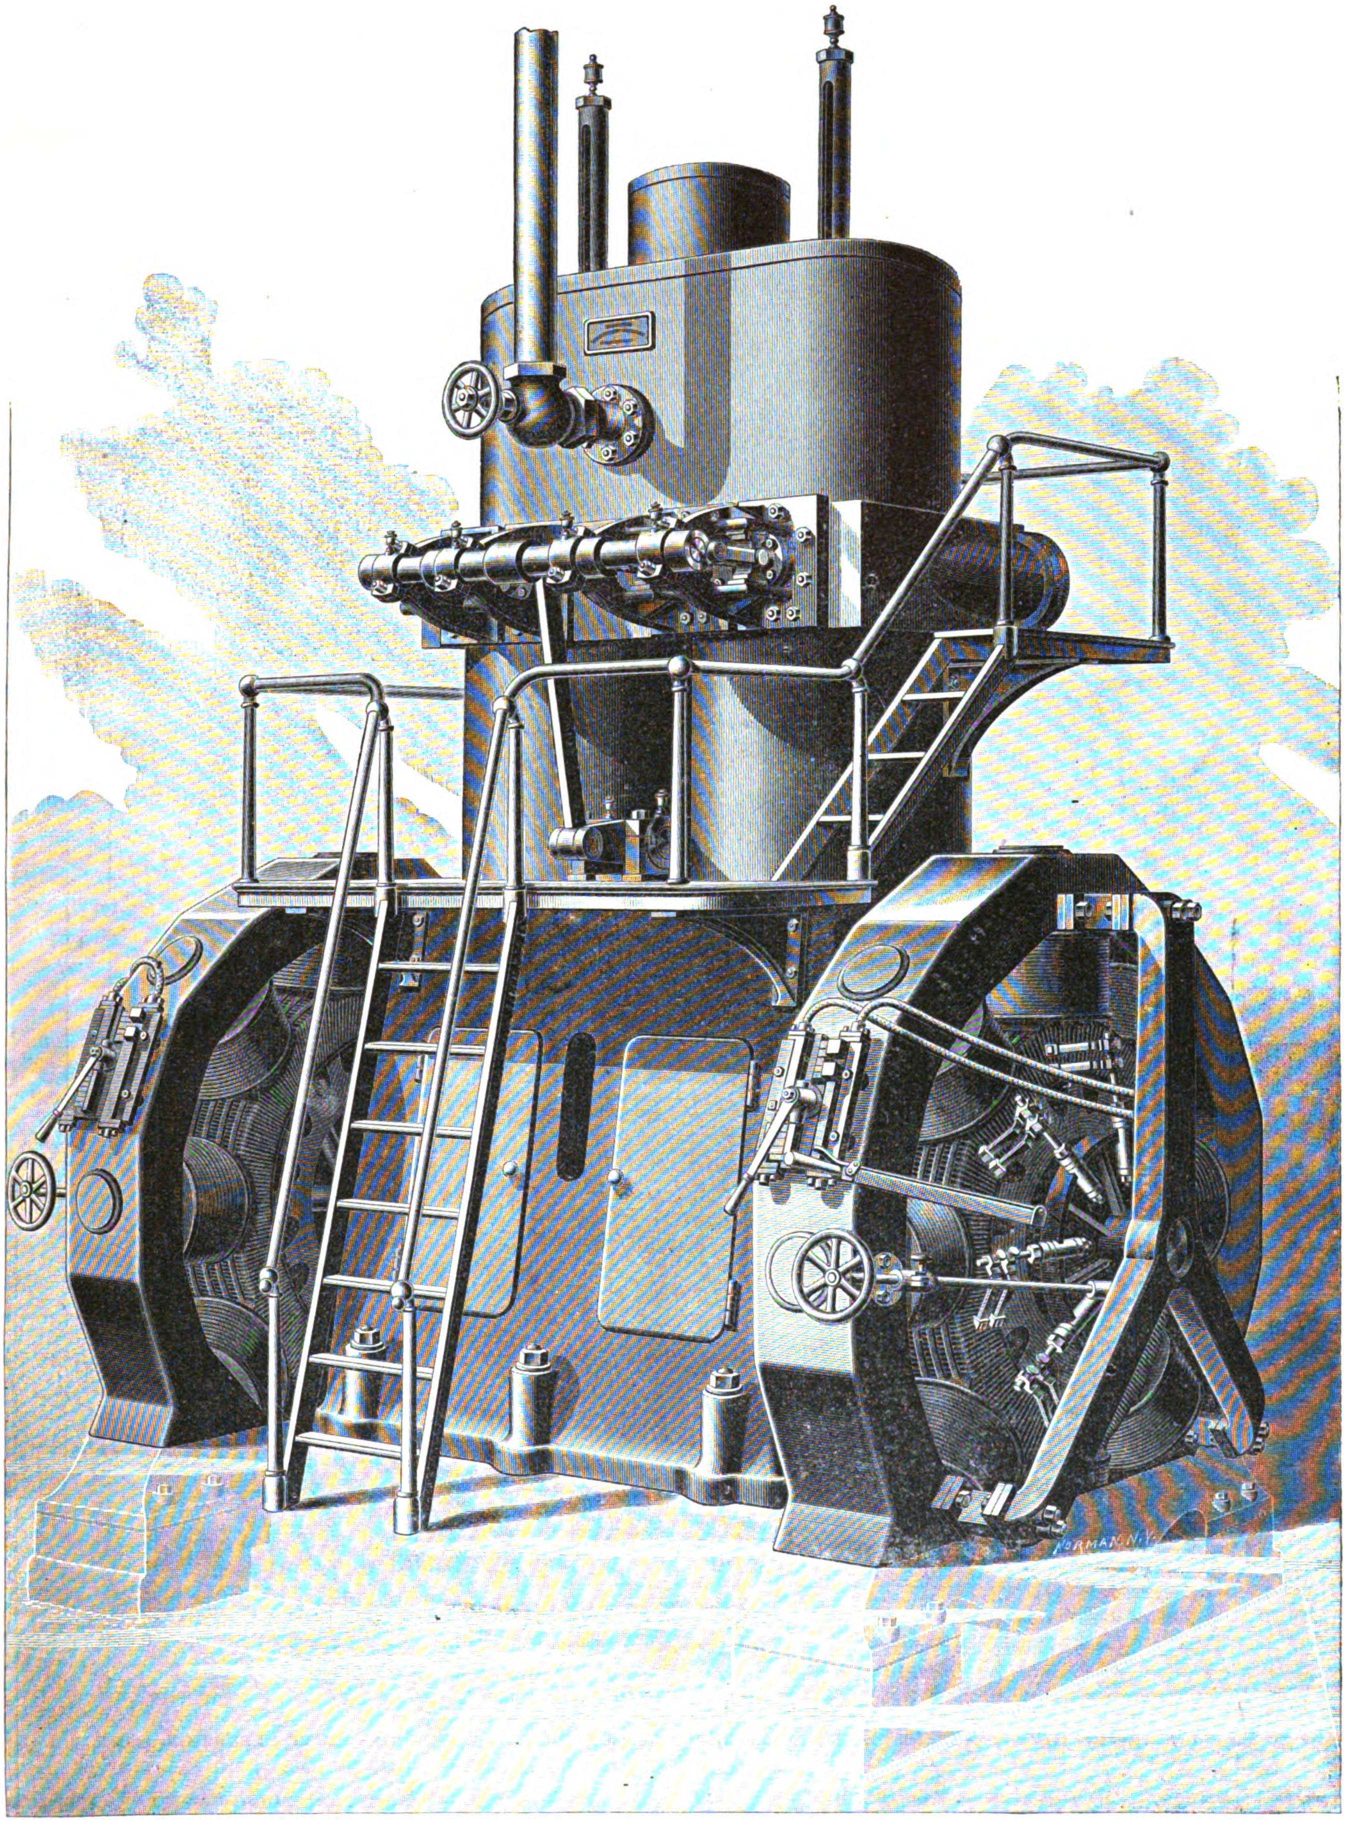

FIG. 1.—THE STRONG VERTICAL TRIPLE EXPANSION DIRECT CONNECTED ENGINE.

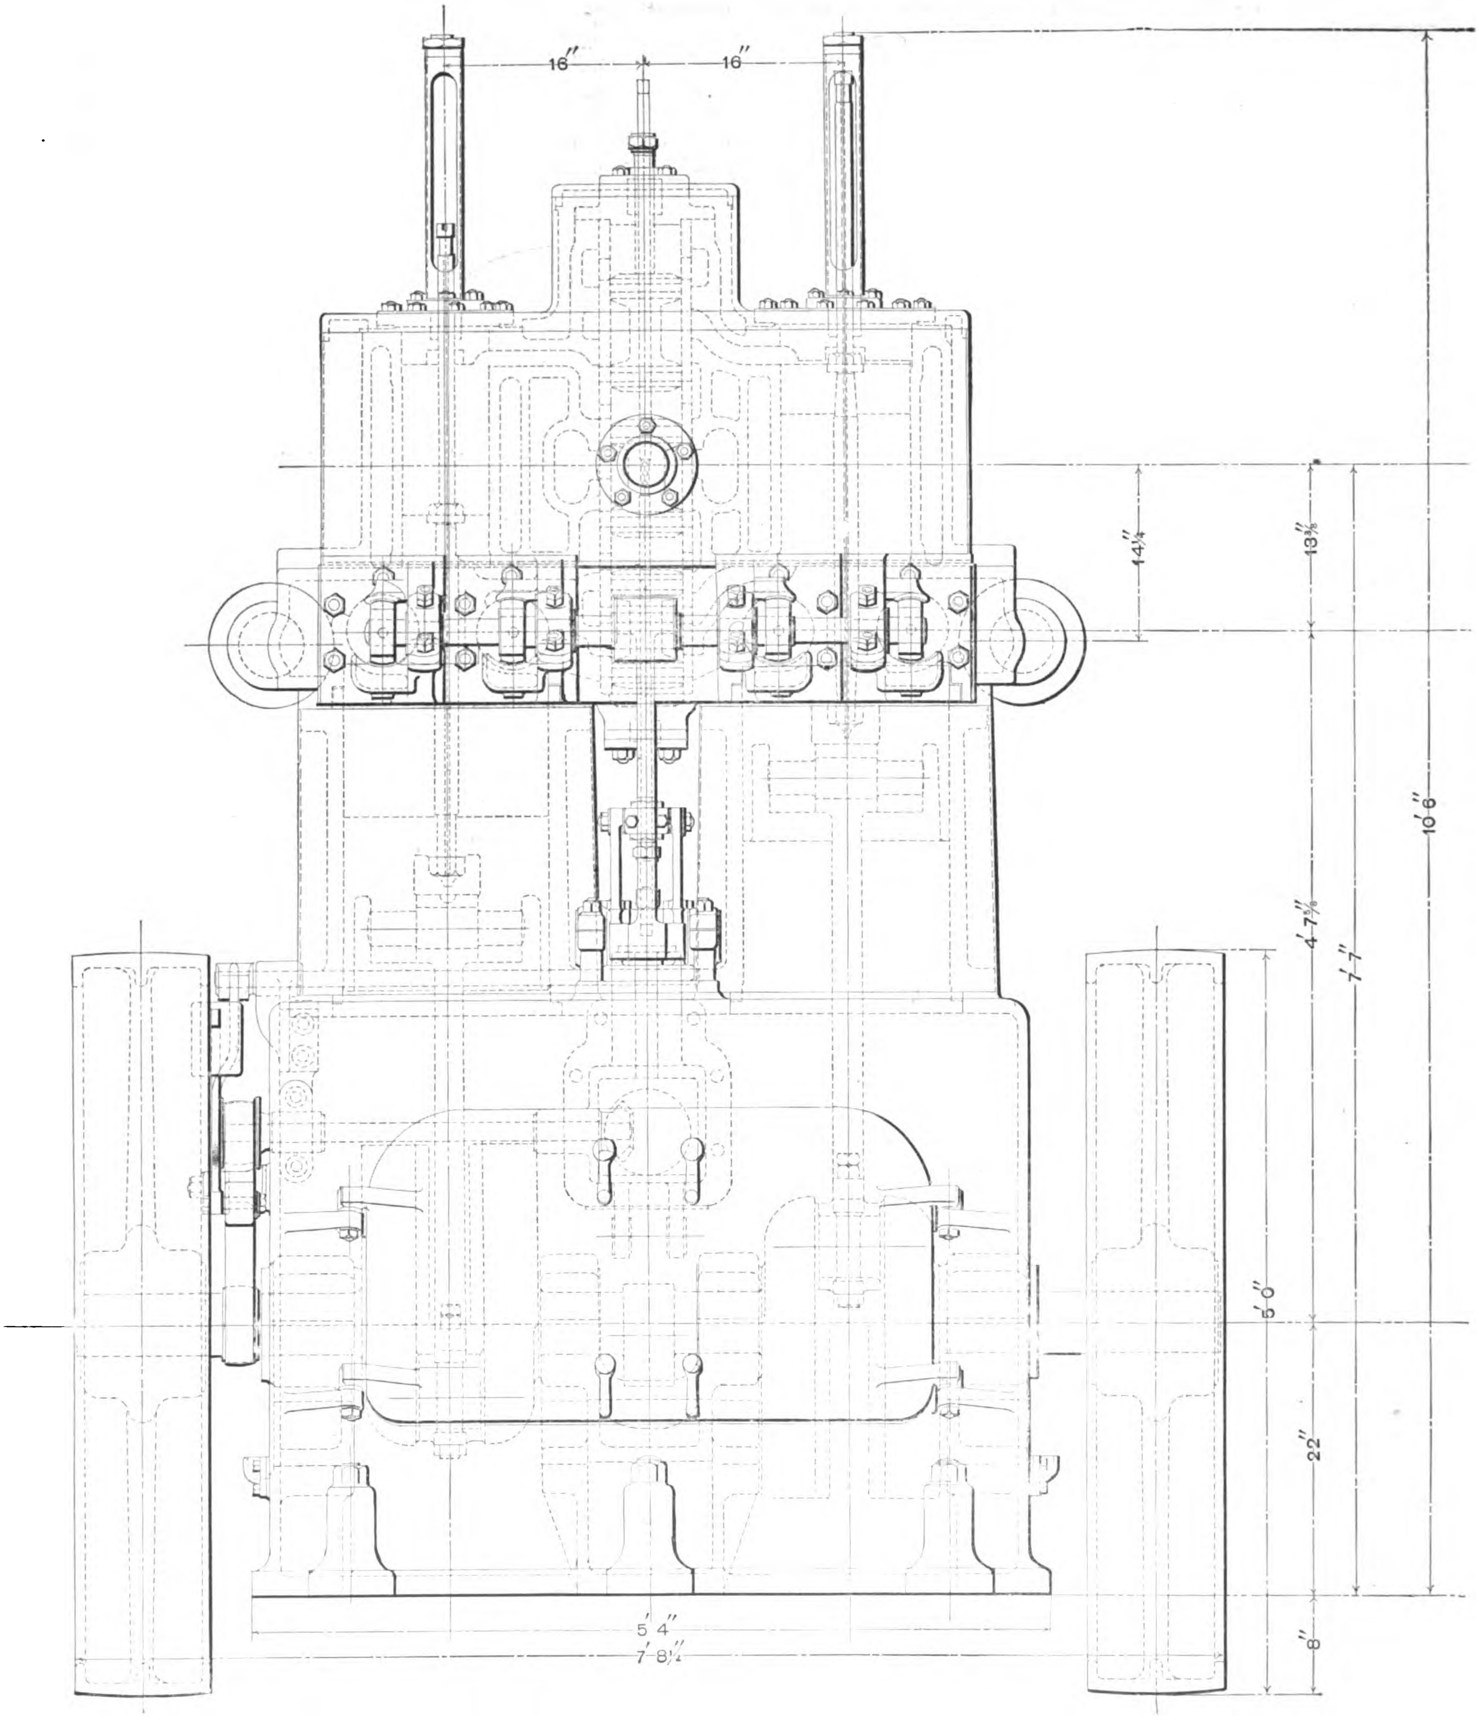

FIG. 2.—THE STRONG VERTICAL TRIPLE EXPANSION DIRECT CONNECTED ENGINE—FRONT ELEVATION.

duced by borings. The valve seats of the gridiron valves are taper plugs with the valve faces milled or planed in them so as to make a plain flat-faced valve in a cylindrical seat which can be easily introduced and easily removed, or replaced.

The piston valve of the high pressure cylinder is actuated by a block sliding in the well-known Fink link, so designed as to give a perfectly equal lap and lead, and at the same time equal cut-offs at both ends of the cylinder. The position of this block, and, therefore, the cut-off, is

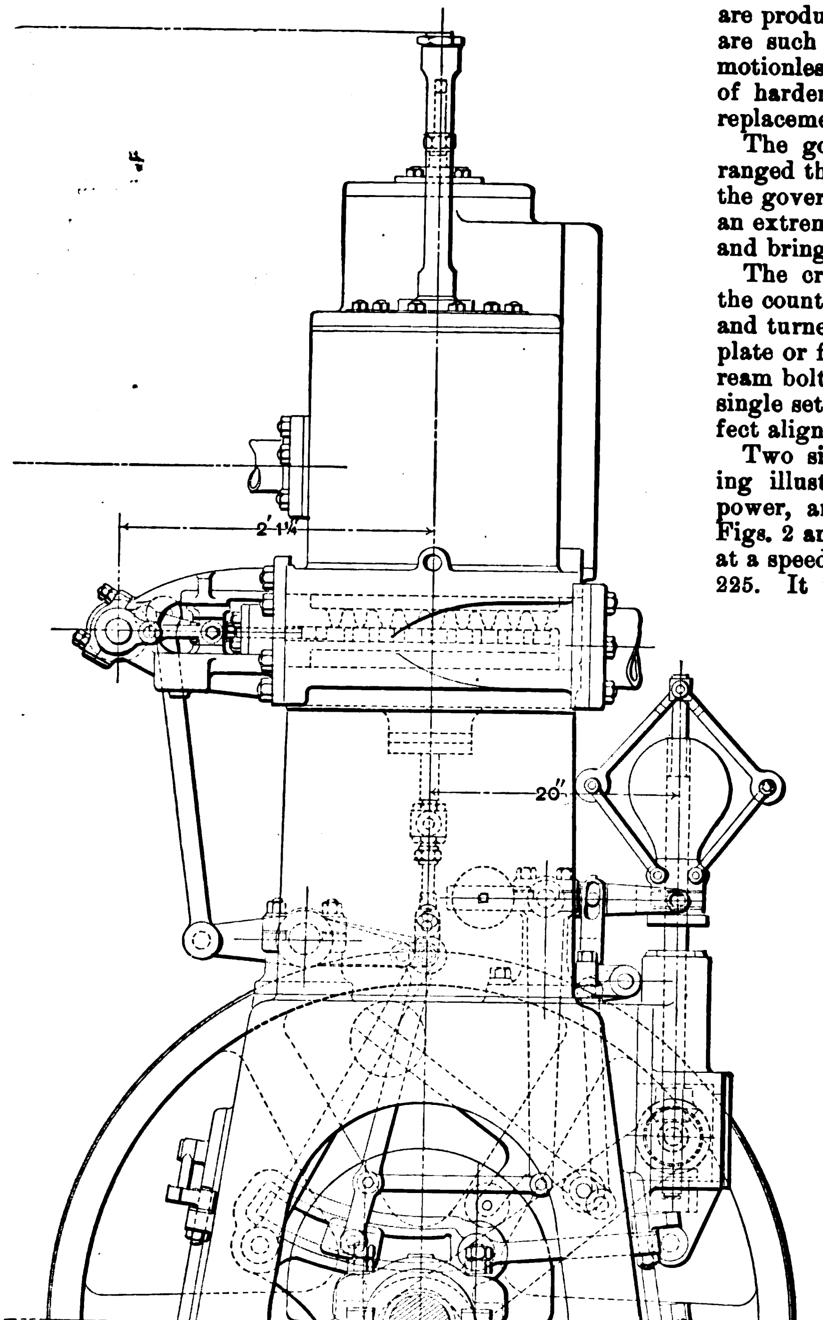

Fig. 3.—The Strong Vertical Triple Expansion, Direct Connected Engine—Side Elevation.

controlled by a sensitive high-speed governor, the resistance to the movement of which is very slight. The exhaust of the high pressure cylinder and the admission and exhaust of the intermediate cylinder are controlled by a connection to a fixed point at one end of the link. These valves have a fixed travel and point of cut-off. The movements of the low pressure valves, both inlet and exhaust, are produced by the same connection to the Fink link, and are such that when these valves are unbalanced they are motionless. All pins and bushings in the valve gear are of hardened steel, thus reducing the wear and rendering replacement easy.

The governor is provided with a safety device, so arranged that in case the governor belt breaks, the arms of the governor will be elevated and the link block thrown to an extreme position, thus cutting off the supply of steam and bringing the engine to a stop.

The crank shaft is forged from a solid steel ingot, and the counter-weight is bolted on. The pedestals are bored, and turned on their bases to fit a bored seat in the bedplate or frame of the engine, to which they are secured by ream bolts. The seats for these pedestals are bored by a single setting of a boring bar, and are consequently in perfect alignment.

Two sizes of this engine are shown in the accompanying illustrations, Fig. 1 being of 150 indicated horse power, and the other, of which two views are given in Figs. 2 and 3, of 250 indicated horse power. The first runs at a speed of 300 revolutions per minute and the second at 225. It is the intention of the builders to manufacture these engines in sizes up to 2,500 h. p.

The engine is manufactured by the Providence Steam Engine Co., who build the well-known and excellent Greene automatic cut-off engine. The details of the engine have been worked out under the supervision of Mr. F. W. Dean, of Boston, Mass.

ELECTRIC LUMINOSITY OF VACUUM TUBES.

In the course of a discussion before the British Association on a paper by Prof. Schuster on "Primary and Secondary Cells," Mr. Crookes stated that if a long vacuum tube containing oxygen exhausted to a point giving the greatest luminosity is held somewhere near a plate connected with one of the terminals of a high-tension coil, it becomes very luminous. If the tube has been lighted and put in a cool, dark place, and thereafter held near a coil, it remains dark, and no amount of placing it near the coil will make it luminous. If the tube is rubbed, it suddenly flashes into luminosity, and remains so; but if laid down in a dark room for an hour, it becomes non-sensitive again. It seemed to him that the gas inside the tube requires to be put in a state of dissassociation. Prof. H. Von Helmholtz, who was one of the lions of the meeting, said he believed that in these vacuum tubes, if there is a little stratum of gas adhering to the surface there are always molecules, which can be separated into positive and negative. There is really a measurable stratum of air adhering to the interior of the glass tubes. If a rarefied vacuum is made, the greater part of that air goes away; but there are always traces of gas left, even in the vacuum of a glass tube which is completely melted.

TESLA MOTORS IN EUROPE.

We understand upon good authority that the reports current in Europe as to the control of Tesla motors secured there by leading concerns are well founded. Three of the largest engineering firms on the continent have acquired the rights for the motor in their respective territories and will proceed to introduce it on a large scale. The concerns are, Ganz & Co. of Buda Pest; the Helios Co. of Cologne, and Schneider & Co. of Creusot, France. The delays usually attendant upon commercial negotiations have been unduly prolonged by the conditions of affairs in Europe; but now that the ground has been cleared, work will be actively pushed. In this country, the Westinghouse Co. have the control of the Tesla motor, and will now push it vigorously.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 203 *Broadway, New York City.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

VOL. XIV. NEW YORK, SEPTEMBER 28, 1892. No. 230.

Electric railroading is here for our upbuilding and national prosperity, as surely as steam railroading was fifty years ago.—G. W. Mansfield.

THE STATE STREET RAILWAY MEETING.

WHILE a very quiet and unpretentious affair in its way, the annual meeting of the Street Railway Association of the State of New York is not to be despised, and the convention this year at Saratoga Springs accomplished, as usual, some interesting and valuable work. We have our doubts as to the likelihood that State associations will increase. They have been tried in the electric light field and have failed, and now that the tendency towards unification of ownership of the lines in each community is so marked it may be questioned whether the street railway interests can maintain many gatherings outside the yearly national one. In a large state like New York, however, there will always be plenty of material for a strong and influential association, and it should be the aim of every street railway man to lend his support to the body. This year, at Saratoga, a most significant new departure was made in the formation of a supply men's association to work in co-operation with the street railway organization on all matters in which support may be desirable. We should not be surprised to see this action repeated on a larger scale next month, at Cleveland, and we would certainly commend it to the notice of the electric light and supply trade, some well-meaning members of which have more than once imagined that their interests lay in antagonizing the National Electric Light Association.

It must strike everybody that, no matter how much New York City may have lagged behind, New York State is wholly and heartily committed to the electric railway. At this meeting, all the roads represented were electric, and the resolutions adopted congratulating this city on the starting of its first trolley cars showed how eagerly the State at large has been waiting for this city to fall into line. Not only was this so, but the address of President Beckley and the report of the executive committee both commended electricity, and the remainder of the session was given up to the discussion of Mr. L. H. McIntire's able paper on the present situation of affairs in electric traction.

There are a number of important questions raised in Mr. McIntire's survey of the various departments of work, and the opinions he expresses are not likely to be accepted by everybody, though it may be hard to gainsay him. Thus it is evident that he favors a deep girder rail, and would abandon the supplementary wiring of the tracks, depending entirely on good bonds. He believes that very few eight-wheel cars will be seen. His preference is for a medium sized car. He likes the multipolar generators and is in favor, therefore, of large units, but is wary of saying what a "large unit" is. He offers the excellent and timely suggestion that there should be a better method of designating the actual capacity of motors. "Horse power" means absolutely nothing, and perhaps Mr. McIntire's idea that motors should be rated by the draw-bar pull, is the most feasible plan. A point that was touched on in the paper and taken up in the discussion was the means of helping passengers to distinguish cars at night-time. Where a company runs a dozen lines and wisely has all its cars alike, so as to be available for any single line, it becomes a serious question how to distinguish cars simply and easily at night. Colored lights don't appear to be adequate, even with big bull's-eyes.

SPECIAL AND SPECTACULAR LIGHTING.

THE present issue of this journal furnishes remarkable evidence as to the growing appreciation of the electric light for decorative purposes and as a special feature of attraction. Mr. Shaw's interesting article reveals the modern search light installed on the top of Mount Washington, at the expense of railways and hotel proprietors, and irradiating the country for a hundred miles with its flashing dots and dashes. Should we ever talk with Mars it must be in some such way, one would think, but in the meantime, it is evident that a new method of earthly communication has been secured.

While Mount Washington affords one illustration of the flexibility and utility of the electric light, the illuminations at St. Louis, of which we give a detailed account, supply the other example. The Emerson Company has shown remarkable ingenuity in this work, which opens up a new and valuable department of applied electricity. Last year at Detroit, as this year at Washington, the Grand Army Encampment has seen some beautiful electrical displays, and New York and Chicago during the coming Columbus celebration will again exemplify the advantages and beauties of this modern form of decoration.

Stanley Transformer Tests.

THE theory of transformer action is gradually getting to be thoroughly understood and may be said to follow in a certain time lag upon the improvements in transformers. We are constantly recording increased efficiencies at all loads, and this week publish the results obtained by Prof. H. J. Ryan on a Stanley transformer. The results obtained leave little room for doubt that the lightly loaded transformer will soon lose its terrors for the station manager.

THE ACME STORAGE BATTERY FOR STREET RAILWAY WORK.

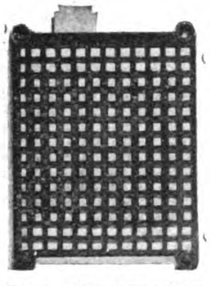

Fig. 1.—The Acme Storage Battery Plate.

When the first elevated railway in New York was put in operation, not many years ago, it was believed that the question of rapid and economical transit for its inhabitants had been solved, not only for the present but for many years to come, but in less than a decade it was found that the facilities which they offered were inadequate to the demands of the public. The result has been that the rate of speed on these roads now exceeds but very little that of the horse cars. Pending the construction of underground railways the surface roads are still taxed to their very utmost and have for years been seeking to increase the carrying capacity of their lines in which one important element is increased speed of their cars with higher economy in the motive power than can be obtained by means of horses. The success of electric traction in other cities in the United States has pointed the way to the solution of this problem but the objection to the employment of the trolley has naturally brought about the consideration by the New York companies of storage batteries for the propulsion of their cars. The experiments which have already been carried out in this city have not lacked in demonstrating the feasibility of this method of operation, which indeed is now well established by the cars in operation abroad, especially in Paris. It may be safely claimed, however, that if storage battery cars, properly equipped, were put upon a road in New York City to the entire exclusion of horses the result would be entirely satisfactory. That the faith of street car managers in this respect is still unshaken is evident by the renewed attempts which are being made, and we are glad to be able to note that the Ninth Avenue Railway Company, in this city, has again taken up the subject with a view to the adoption of storage battery cars.

As a preliminary step this company has given the Acme Storage Battery Manufacturing Co., of this city, an opportunity of demonstrating the feasibility of storage traction, and we were last week privileged to ride upon the car equipped with the Acme cells. This car, which weighs 6½ tons, is equipped with 144 cells, each weighing 27 pounds complete, and having a capacity of 140 ampere hours at an average discharge rate of 25 amperes. The car left the stables, at Fifty-fourth street and 9th avenue, and proceeded up the road on the regular track to One-hundred-and-sixteenth street, a distance of three miles. The grades on this road are exceedingly heavy, one of them, at the end of the route, being no less than six per cent. for a distance of more than 600 feet. On this grade the battery was called upon to deliver 75 amperes, while the average reading of the entire up-trip was 31 amperes. The time occupied was 24 minutes and 50 seconds.

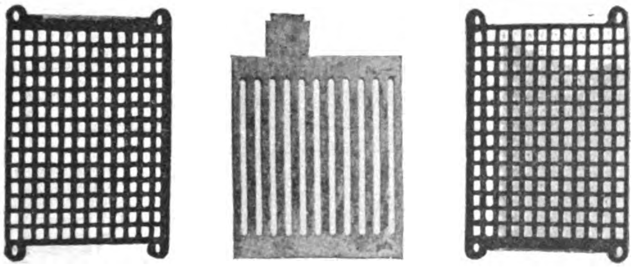

Fig. 2.—The Acme Storage Battery Plate.

On the return trip, during which the grades were mostly descending, the average current drawn from the battery was only 19 amperes, or little more than half of that required on the up-trip, the time occupied being 22 minutes and 30 seconds. The entire trip of six miles was made in 47 minutes and 20 seconds, and the car in every way operated smoothly and was shown to be under perfect control, eliciting much favorable comment from a number of street railway officials, and others present, who undertook the trip.

The Acme Storage Battery Manufacturing Company have started out to develop every detail in their work and employ a specially designed motor. Much of the success of such a system must naturally depend upon the battery employed and to this branch the company has devoted particular attention. Their aim has been to construct a cell which, while having the least weight for its storage capacity, shall, at the same time, be so constructed as to avoid the deteriorating influences which have in the past caused rapid destruction of storage cells employed in this class of work. In the carrying out of these designs the company has employed a storage battery built up in a special manner, which is well illustrated in the accompanying engravings. Each plate consists of a thin, slotted sheet of lead having a projecting tongue for making connection between adjacent plates. This thin sheet is then surrounded by the active material which is held in place by grids made of insulating material which are placed on either side. The four holes shown at the corners of the grids serve for the insertion of the bolts, which maintain the grids in position, and, passing through the successive elements, bind them all into one solid mass which is able to successfully withstand the severe service imposed by street car traction. The engraving Fig. 1 shows one plate with the grids complete. Fig. 2 shows the grids and lead sheet taken apart.

The company operating the car are confident that with the improved battery above described and their motor they can show the economy of storage battery traction, and it is to be hoped that they will be afforded every opportunity for their present tests.

A BIOGRAPHICAL SKETCH OF THE KHOTINSKY ACCUMULATOR.—III.

BY

Capt A. de Khotinsky

In November, 1881, the manufacture of gaufré accumulators was transferred from the laboratory of *l'Electricien* to that of my established manufactory at Rue des Martyres. Here I had opportunity to make an improvement by performing the soldering by electricity instead of by tin.

At this time my friend, Prof. Latschinoff, of St. Petersburg, experimented in my factory at Paris with a solution of lead oxide in caustic soda, to produce electrolytically from this spongy lead and peroxide. These experiments determined me to make an accumulator in which spongy lead was used as an electrode. I pressed spongy lead together in plates and laid between every second plate a lead plate perforated with holes, and wrapped up the whole in a perforated leaden case, as shown in Fig. 12.

This electrode was soldered electrically. The negative plates had twice the weight of the positive plates, because by this time I had accepted the gas theory for the work of accumulators. In May, 1882, in this way, I completed a secondary battery which gave me satisfactory results in the following respects :

1. The formation was accomplished without necessarily changing the polarity in forming it.
2. The forming required not more than three days, after

which time the spongy lead in the positive electrode was completely changed to peroxide.

3. The quantity of accumulated energy was three times greater per kilogram (weight) than with the gaufré accumulator, after the latter had been charged for a month.

All these advantages determined me to devote myself to earnest attention to this new construction. I went therefore to London to see Mr. W. H. Preece, chief electrician of the postal telegraphs, to show him my new element, to get his opinion, and ask for his advice as to the steps I must take for the practical commercial realization of my battery. I had charged my cell completely in Paris, then removed the acid and covered the plates with wet felt to keep them in a moist condition.

After my arrival at London, I filled the cell again with a ten per cent. acid solution. Mr. Preece requested his engineer, Mr. Cooper, to measure the capacity of the present charge in the cell, and Mr. Kempe to measure the resistance of the cells. After two days I went to Mr. Preece to obtain information about the results of these tests. Mr. Preece appeared to be satisfied with the results thereof, and told me he would for commercial realization recommend me to Mr. Arnold White, at that time director of the Edison Company in London, and at the same time president of the British Insulite Company, Limited, in London. Mr. Preece also advised me to immediately apply for a patent.

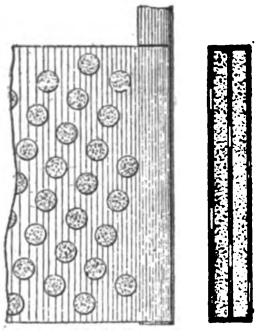

FIG. 12.

After I had made an agreement with Mr. Arnold White, I returned to Paris to arrange for my establishment in London.

In the manufactory of the British Insulite Company in Charlton, a place was assigned me, where I prepared for constructing an experimental battery.

After some months this battery was ready and I could make public experiments for the board of the Insulite Company and others interested. These turned out very satisfactory. To my sorrow, I found that the company was in want of capital, and I was therefore compelled to discontinue for a while my further experiments, of which I shall speak later.

THE "BRAIN" ELECTRIC TRAMWAY SYSTEM.

In our last issue we gave a general description of the above tramway system, to illustrate the operation of which an experimental line has been laid down at the Telegraph Construction Company's works at Helsby, England. We are now enabled to place before our readers further illustrations of this system, for which we are indebted to *Industries*. In Fig. 1 a view showing details of the permanent way are given. Fig. 2 shows a side elevation of the under frame of a car showing the method of connecting the collector trolley to the car frame, and Figs. 3 and 4 show respectively side elevation and sectional view of the collector trolley. Figs. 5 and 6 show enlarged sections of the cover rail and slot in the conduit, the cover rail being shown both seated in its bed and raised similar to when a car is passing.

From Figs. 3 and 4 it will be seen that the carrier frame and contact arrangement are carried on a strong girder G, which is shown connecting the two rollers T that run on the surface of the cover rail. The contact arrangement consists of a sliding contact piece or shoe B, which is attached at each end to the lever rod L, of about $\frac{3}{8}$-inch square steel. Both these levers are moved by one flat steel spring S; thus a constant downward pressure is maintained against the conductor A. The levers (being square) and the upper part of the contact shoe B are fitted into a strong lock frame, in which they work easily. This lock frame is well enameled and insulated, and let into a solid block of hardwood, previously treated with a hardening hydrocarbon insulating liquid. In position, the block overhangs the metal of the box-lock frame like the deep cup of an insulator. The whole is like a long insulator cup with the lock frame up inside. This travels along the slot opening of the conduit, and the thickness of insulation on each side of the metal is more than twice the total width admissible in an open conduit slot. From the contact shoe B the current is taken by the strip conductor D to the grip Z, and from thence by the cable C to the car; W W are the carrier wheels supporting the cover rail B.

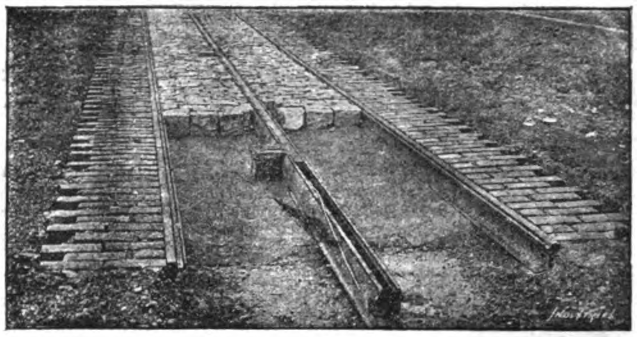

FIG. 1.—THE BRAIN ELECTRIC RAILWAY CONDUIT.

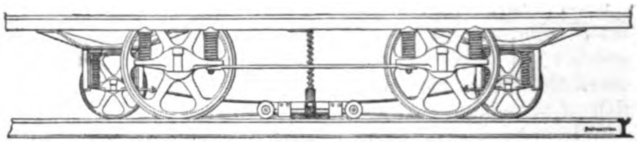

FIG. 2.

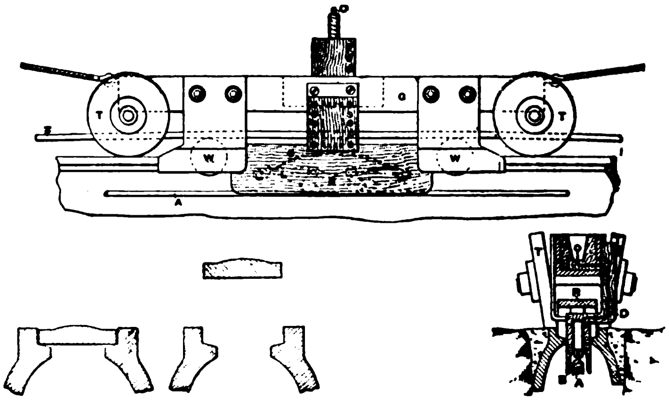

FIGS. 3, 4, 5 AND 6.

At the turnouts and all crossings, the conductors can be made continuous, as at their junctions they are simply made to present a flattened surface over which the contact shoe can easily slide in either direction.

SPECIAL ELECTRICAL ILLUMINATIONS AT ST. LOUIS, MO.

The ready adaptability of the incandescent and the arc lamp to decorative effects is now so generally recognized that these methods of illumination are being employed to the almost entire exclusion of others. The ease with which wires can be run and made to conform to any outline makes the work of illuminating arches or set pieces of any description a comparatively simple matter, while, on the other hand, where changeable light effects are desired the electric method is facile princeps.

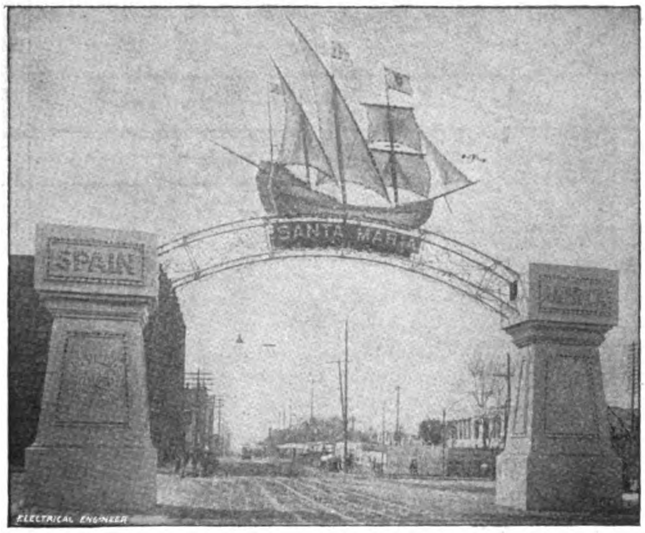

Fig. 1.—The "Santa Maria" Electric Arch.

No better illustration of this could have been found than was exhibited in the illuminations gotten up in connection with the recent autumn festivities and Columbus celebration at St. Louis. These lighting effects, which were all carried out by the Emerson Electric Manufacturing Co., of St. Louis, deserve more than passing notice, and may be said to have constituted the crowning feature of the festivities.

Probably the most elaborate piece is the "Santa Maria" arch, Fig. 1, located on 12th street, between Market and Chestnut streets. The extreme outside dimension of the arch is 70 feet, and the inside distance, from column to column, 45 feet. It spans the double track of the Union Depot Railroad (electric line) and has a clearance of 34 feet at the centre. The arch is made of $2\frac{1}{2}$-inch iron pipe, with special cast iron fittings, and is held together with $\frac{3}{4}$-inch tie rods. The pillars are of wood built around 3-inch iron pipe and a telegraph pole. The ship itself is of $\frac{3}{8}$-inch wood, covered with canvas, and painted.

The electrical apparatus is arranged in three circuits, with separate 500 ampere knife switches. The first circuit includes the ship "Santa Maria;" the second circuit includes all the lights representing the waves, and the third includes all the lights in the columns, names and borders.

The first and third circuit are controlled directly by the switches, while the second circuit is cut in by the switch but goes through an improved contact cylinder driven by a one-eighth horse power Meston alternate current motor. The cylinder takes the different circuits of the waves. By means of the cylinder an excellent imitation of wave motion is obtained. This design is alike on both sides, thus constituting a "double design."

The first circuit contains no less than 750 lights; the second circuit 520, and the third 600 lights, making a total of 1,870 lights. Not the slightest hitch has occurred with this arch since the current was first thrown on, several weeks ago. The highest light is 61 feet above the railroad tracks. Current is supplied by 18 Stanley 100-light converters, situated in the west pillar.

An equally effective piece though of a different nature is the "Flag Arch," Fig. 4, showing side byside the American flag and that of Columbus. This arch is located on 12th street, between Olive and Locust streets, over the statue of Gen. U. S. Grant. The circle enclosing the statue is 25 feet in diameter. The side columns are 19 ft. high, surmounted by four wooden balls representing cannon balls, and an eagle, the distance to the top of the flag pole being 45 feet. Both flags cover an area of 10 x 13 feet. The flag pole and supporting arch are made of iron pipe, the flags being of wood as are also the columns.

The American flag is, of course, red, white and blue. That of Columbus represents the one said to have been given him by Queen Isabella, when he left Palos. It has a white ground, gold border, gold crown and cross, and bears the letters F and Y in green, standing for Ferdinand and Isabella. This is not a Catholic flag as a great many suppose, but the personal ensign of Christopher Columbus.

The lights are divided into two circuits. The first circuit is controlled entirely by its switch. The second comes through its switch and is then divided by one of the Emerson Co.'s cylinders as in the "Santa Maria" arch. This circuit contains all the lights of the flags, each of which is divided into eight circuits. The first circuit of each flag is connected together and then led to the cylinder, and so on with the rest of the circuits. The first circuit contains 590 lights, and the second 630 lights, making a total of 1,220 lights supplied by 11 Stanley converters.

The converters are placed back of the statue and covered over; the cylinder is in the west column. This piece is also a double design.

The piece known as "The New World Pole," which is illustrated in Fig. 2, is located on 12th street, just south of St. Charles street, being one block from the works of the Emerson Co.

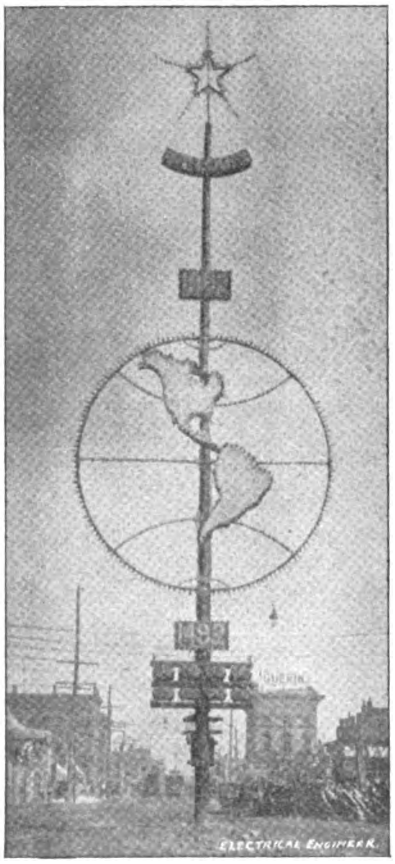

Fig. 2.—The "New World" Electric Standard.

This is the design that was shown, in part, at the St.

Louis Exposition this Spring. It is built around a telegraph pole, about 14 inches at the butt. The circumference of the circle and pipes supporting it are held to the pole by special castings. The circle is 25 feet in diameter and the highest lamp is 93 feet from the ground, being the first lamp in the upper streamer of the star. The continent is made of wood, painted white, and all the iron work and the pole are painted black. There is but one 1,000 ampere knife switch employed with this piece. The different circuits are led to a "duplex contact cylinder" which is shown in the engraving, Fig. 3.

The lights are arranged in the following order : 1. Red lamps in circle ; 2. White lamps in circle ; 3. Blue lamps in circle ; 4. Border of dates ; 5. "1492" and single lamp for "San Salvador ;" 6. The lights begin at the Gulf of Mexico and go around the continent to about New Foundland and down to the mouth of the Amazon, when all the rest of the continent comes in with the geographical circles. 7. "1892 ;" 8. St. Louis and Star ; 9. The circle is made to appear to revolve ; 10. When the circle is revolving the star is made to twinkle.

It is said the flashing of this star 90 feet high can be seen for miles on a clear night. In this piece there are 1,360 lights fed by Stanley 100-light converters. The "New World" cylinder is operated by a duplex cylinder driven by a $\frac{1}{8}$ h. p. Meston alternating current motor at 105 volts. The vertical cylinder brings in all the different effects as mentioned above and at a certain time the horizontal or fast cylinder is cut in and gives the twinkle to the star and the revolving to the circle. There are 24 distinct circuits in this cylinder.

The "Pyrotechnic Arch" is located at Seventeenth and Olive streets, just at the crown of a hill, from which it can be seen a long distance in either direction, especially from the west.

This arch has a span of 38 feet and a clearance of 25 feet. It begins at the centre of the board and lights up each of the designs separately, then the lights flow out, as it were, along the supports and up the pole by degrees until the umbrella is reached, where it remains a while, then goes out, and then begins over again.

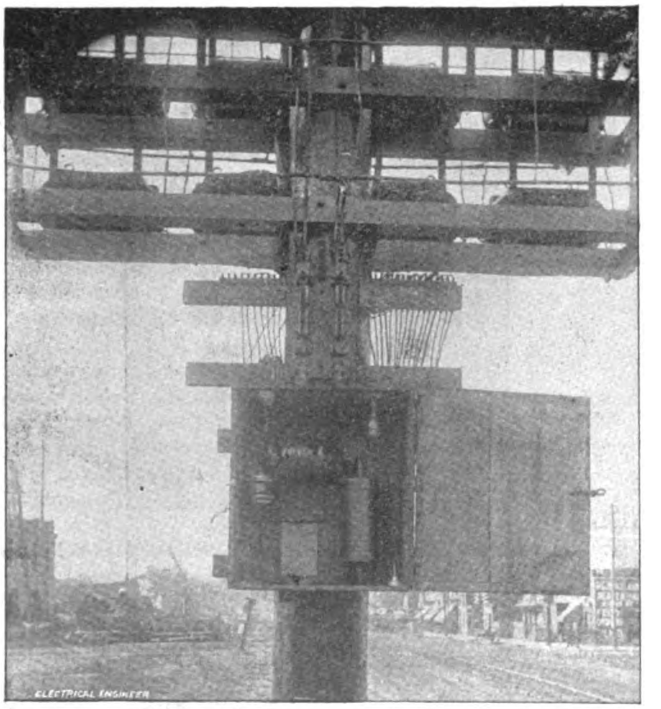

FIG. 3.—CYLINDER SWITCH FOR CONTROLLING ILLUMINATIONS.

There are 650 lights arranged in 20 distinct circuits, in this arch, controlled by a 500-ampere knife switch and a single contact cylinder driven by a $\frac{1}{8}$ h. p. motor.

The "Columbus Arch" is located at the corner of Olive and Thirteenth streets, just east of the Exposition Building. Its dimensions are the same as those of the "Pyrotechnic Arch." It bears a transparency of Columbus in the centre, lit up by 380 lights and one arc light in the interior. This piece has no moving effects.

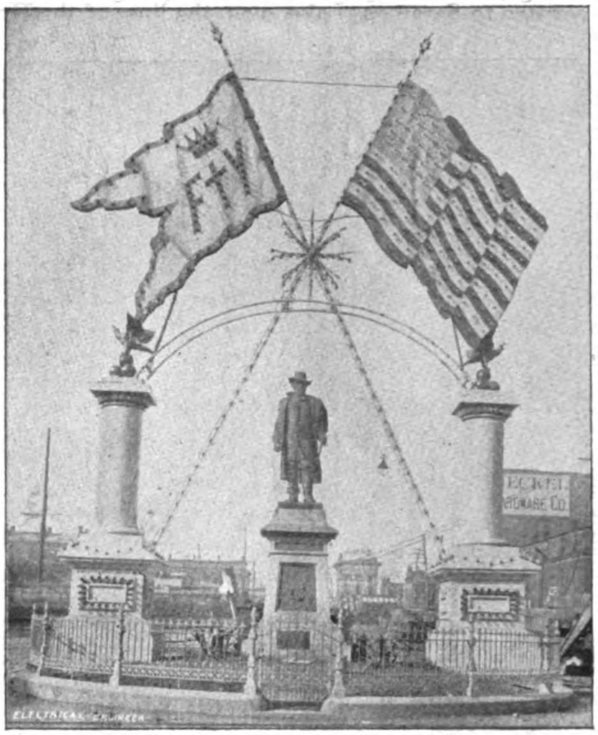

FIG. 4.—THE "FLAG" ELECTRIC ARCH, ST. LOUIS.

The "Washington Transparency" is located at the corner of Broadway and Washington avenue. It is placed on top of a boulevard pole of the Lindell Street Railway Company (electric line). The transparency is illuminated from within by means of an arc light and the borders are out-lined by 140 lamps run from a Brush converter.

These pieces constitute probably the most elaborate installations of this character thus far undertaken in this country and might afford valuable suggestions to the numerous Columbus celebration committees now at work.

Patent Notes.

THE CARPENTER ENAMEL RHEOSTAT.

IN a patent just issued to Mr. Chas. E. Carpenter, entitled, Rheostat, No. 481,781, Aug. 30, 1892, the inventor describes the ingenious enamel rheostats recently illustrated in our columns. The patent is assigned to the Carpenter Enamel Rheostat Co., of Bridgeport, Conn., and is claimed to cover the controlling features of this form of rheostat. The patent was filed Feb. 18, 1891, and contains the following claims :

1. A rheostat or resistance comprising a base plate corrugated, ribbed, or recessed on the rear face thereof and provided with a coating of enamel or similar vitreous material on the front face and resistance coils or sections embodied in such coating, substantially as and for the purpose described.

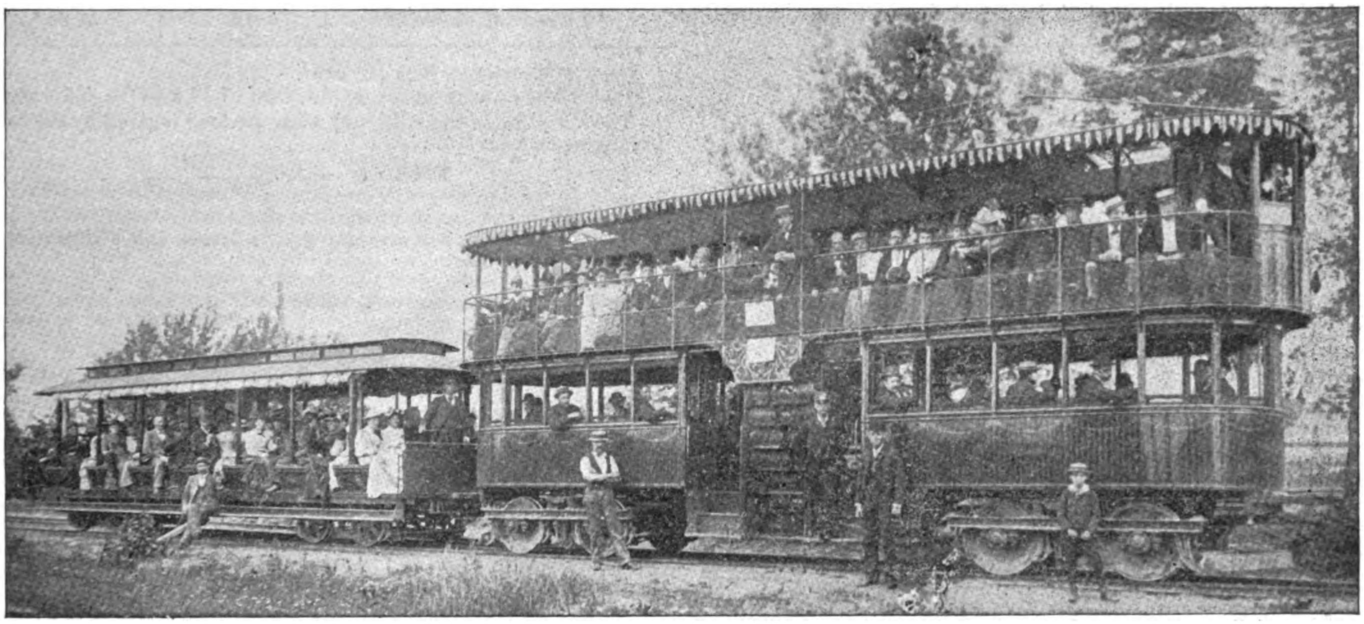
2. A rheostat comprising a base plate provided with a coating of enamel or similar vitreous material, a series of resistance coils or sections, and a corresponding series of contact blocks therefor embedded in such coating, and a switch key co-operating with such series of blocks, substantially as described.

3. A rheostat comprising a base plate provided with a coating of enamel or similar vitreous material, a series of resistance coils or sections, and connecting wires embedded in said coating beneath the surface thereof, but out of contact with the base plate, a corresponding series of contact blocks also embedded in said coating, but projecting beyond the surface of the same, and a switch key co-operating with the series of blocks, substantially as and for the purpose described.

We understand that applications for a number of additional patents of importance covering the manufacture of enamel rheostats will soon be put through the Patent Office.

THE PULLMAN DOUBLE-DECKED ELECTRIC CARS AT SARATOGA SPRINGS.

One of the most interesting features of the meeting of the New York State Street Railway Association last week at Saratoga, was the trip made from the Springs out through the country to Saratoga Lake, over the line of the Union Electric Railway Co., by invitation of Mr. C. E. Arnold, the president of the company. The ride was made in a car of the new centre vestibule, upper-seat type, now being introduced by the Pullman Co., of Chicago, and as few of the street railway men even had seen these cars, the element of curiosity intensified the pleasure of the excursion. It was a critical party, but unless the signs are greatly mistaken, it was a verdict of approval that was given. The opinion of the writer—who was present, and who has ridden on every type of electric car, since Mr. Leo Daft experimented with his at Saratoga nine years ago—is one of entire approval. It seems to him that such cars must solve the problems of heavy summer travel, and meet many conditions of normal traffic on crowded city lines.



The Pullman Double Deck Car at Saratoga Springs, N. Y.

A picture is here given of the car with a trailer. There are four of these double-deckers on the road, which has also eight Pullman trailers, four single-truck motor cars, and five single truck trail cars, or twenty-one cars in all, the motor and power equipment being of Thomson-Houston make. As will be observed from our illustration, the Pullman double decker is eight-wheeled, and consists below of two compartments. It is 32 feet long over the body proper, and has a total length of 33 feet 7 inches. Its body width is 7 feet 4 inches, and its height is 14 feet 9½ inches. Each of the lower compartments is 12 feet long. The lower floor will seat 40 passengers, and the upper 40 more; while many times during the past season the car has carried 150 passengers for several successive trips, as well as hauled its trailer. It has even done much better than that, but of course the capacity is limited by the ability of the motors, which are two of 25 h. p. each. The spiral stairways occupy about the same space—eight feet—as is usually devoted to the end platforms, and the pilot houses are up on the second deck, handy to the trolley and giving a fine point of vantage for looking well ahead on the track. The upper deck is covered in by a very handsome and substantial canopy, and the car above and below is well lighted by no fewer than 25 incandescent lamps. The Pullman trucks that carry the admirably distributed weight of the car are fitted with Allen paper wheels.

Judging from personal experience, riding in these cars is a most agreeable pastime. In the lower compartments, one seems to be occupying a choice seat in an observation car on a steam road. Upstairs the seats are broad, easy and nicely shaded. Even when the car has its heavier load on top, with the down stairs compartments nearly empty, it travels easily and smoothly with very little, if any, tendency to tilting. This stability, due to a low centre of gravity, was particularly noticeable at high rates of speed, both on grades and curves, the rate made ranging from 8 up to fully 25 miles an hour.

The road is new, having started only on July 1, but thanks to these cars and their enormous carrying capacity, it has been a pronounced success and has done a very large business. The road has often carried in a day from Saratoga Springs to the Lake, 3,000 passengers at 25 cents the round trip; 1,500 to the Geyser Spring at 10 cents and 1,000 to the Race Track, when the races are on, at 20 cents. These are excellent rates of fare, but the road has found it possible to get them and to be inconveniently crowded. Provided with such sumptuous and enjoyable accommodations, the public that visits Saratoga has felt itself well treated, and the patronage has been of the kind that always responds to liberality of management. In conversation with officers of the road, the writer learned that so far as they could discover, it took practically not an ampere more of current out of the station to run one of these cars than it did to run one of the ordinary motor cars, and yet the earning capacity was doubled absolutely.

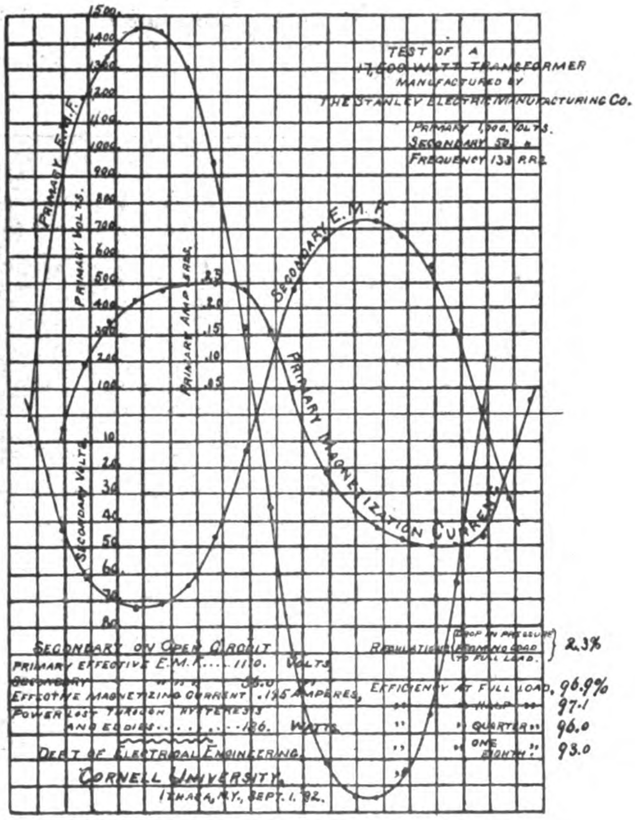
THE TOMMASI MULTIPOLAR ACCUMULATOR.

The Tommasi accumulator is now being manufactured in three sizes by Messrs. Rouart Bros., of Paris. Their charging current varies from 1 to 4 amperes per kilogramme of plates, and the discharge from 1 to 3 amperes. The available capacity in ampere hours, under a discharge of 1 to 3 amperes per kilogramme, is 20 ampere hours per kilogramme. The price of the accumulators is 30 francs per ampere hour. The Tommasi multitubular, it will be recalled, is formed of electrodes enclosed in a sheath of insulating material pierced with holes. In the centre of the sheath is a lead conductor in contact with a layer of oxide.

TEST OF A STANLEY 17,500-WATT TRANSFORMER.[1]

The method employed for testing your 17,500-watt 1,000 x 50 volt transformer for a frequency of 132 periods per second, was as follows:

The power dissipated through hysteresis, eddy currents, etc., was determined by the use of a contact maker, condenser, and electrometer as described in the paper on transformers in the *Proceedings* of the American Institute of Electrical Engineers, Vol. vii, p. 1. The transformer received current from a Westinghouse alternator at 132 p. p. s. This machine was driven by a high speed 60 h. p. tandem compound automatic engine, that has a fair speed regulation. It was found in the outstart, however, that the total loss of power in the transformer at full load was in the neighborhood of but 3 per cent. of the load. On account of the natural drift of the speed of the engine within certain limits, it was not found practicable to measure the total power delivered to the transformer and that given out by it with such a degree of accuracy that the probable error would be less than 1 per cent. This would mean a probable error in the determination of the total power dissipated by the transformer of 30 per cent.



Test of Stanley Transformer.

Were there no magnetic leakage in transformers, we would get a measure of the power lost through heating of the primary and secondary conductors by the product of the drop in volts observed on the secondary into the current output of the same. This measure would then be rigidly accurate when the secondary is at work on incandescent lamps, and the primary magnetizing current is as small as it is for this transformer. Actually, however, there is always some magnetic leakage that increases with the output of each transformer, and lowers the E. M. F. of the secondary by lessening the magnetization through the same. Since this action results in no waste of power, in ignoring its presence we shall make an error that counts against the transformer. It is highly probable that in a transformer with a drop in pressure due to load of only 2 or 2½ per cent., the error thus made against the efficiency at full load will not amount to more than ⅛ per cent.

The drop of secondary pressure due to load was observed by taking simultaneous readings of the effective pressure at the terminal of the primary and secondary when the transformer was loaded with lamps to an output of 17,500 watts and when it was unloaded. In this way errors due to the drift of the speed of the engine are eliminated.

The accompanying diagram with its curves gives graphically the observations made for determining the power taken up by the transformer with the secondary on open circuit. From the curves of primary impressed E. M. F. and primary current the power lost through hysteresis and eddies in the iron core, was determined to be 186 watts with the pressure at the primary terminals of 1,110 volts. It is desirable to know the power lost at the standard pressure of 1,000 volts. In making this deduction we have assumed that this loss varies as the 1.7 power of the magnetic density in the iron core. The power lost in the transformer on open circuit at a primary pressure of 1,000 volts is therefore 157 watts.

The drop in the secondary pressure due to load was determined from the following effective primary and secondary pressure readings which are given as the mean of a number of observations:

Full Load.		No Load.	
Primary.	Secondary.	Primary.	Secondary.
1,077	53.30	1,122	57.03

Reduced to a primary pressure of 1,000 volts:

Full Load.		No Load.	
Primary.	Secondary.	Primary.	Secondary.
1,000	49.67	1,000	50.83

Drop 1.16 volts, or 2.32 per cent.

Power lost in heating the conductors: 1.16 x 350 = 406 watts.

The variation of the efficiency with the load is given by the following equation:

$$\text{Efficiency} = 100 \frac{W}{W + H + K^2}$$

Where W = the output of the transformer in watts;
H = the power lost through hysteresis and eddies in the core;
K^2 depends upon the effective resistance.

Substituting the numerical values of H and K, we have:

$$\text{Efficiency} = 100 \frac{W}{W + 157 + .00000132\, W^2}$$

The efficiencies at full load, half load, quarter load and one-eighth load are 96.9, 97.1, 96.0 and 93.0 per cent, respectively. For one 16 c. p. lamp the efficiency is about 24 per cent.

For a determination of the all-day efficiency when the primary pressure is kept up at all hours of the day it is assumed that this transformer would have a working output equivalent to 17,500 watts for five hours out of every 24. Under these conditions the all-day efficiency is 93.8 per cent.

GOVERNING WATER WHEELS.

In the last issue of The Electrical Engineer I noticed an article on the difficulties of governing water wheels when the load under which they operate varies. The writer of the article has pointed out the reason why it is impossible to design as quick-acting a water wheel governor as some of our steam engine governors. The remedy he suggests when viewed from a practical electrical standpoint can hardly be recommended.

Whenever we have to deal with water powers having a small head and a large volume, I think the best plan is to use as quick acting a governor as circumstances will allow, and in addition, use either a very heavy fly-wheel or a generator having an armature of very large diameter, such as has been placed on the market by the General Electric Co., Siemens & Halske and others.

For water powers operating under a large head, I think the best plan is to use a deflecting nozzle such as is employed by the Pelton Water Wheel Co. With this device, whenever the load is diminished, the nozzle is deflected so that but part of the water stream strikes the buckets. This, together with as large and heavy a wheel as feasible ought to make a very good governor. It is, of course, for the water wheel companies to say whether any practical difficulties prevent the use of this device.

The amount of water used in this case will be always the same whether the generator is working under light or full load, but this is not of great importance, as it would, as a rule, be very foolish to try to use a water power when only sufficient water for the average load is available. A successful water power plant requires an abundance of water during all seasons of the year.

Wm. M. Schlesinger.

Butte, Mont., Sept. 16, 1892.

TENTH ANNUAL MEETING OF THE NEW YORK STREET RAILWAY ASSOCIATION.

THE tenth annual meeting of the N. Y. Street Railway Association was held at the United States Hotel, Saratoga Springs, on September 20.

The following gentlemen were present:

John W. McNamara, president, Albany Railway, Albany; Daniel F. Lewis, president, Brooklyn City Railroad Co., Brooklyn; W. J. Richardson, secretary, Atlantic Avenue Railroad Co., Brooklyn; Joseph A. Powers, superintendent, Glens Falls Electric Railway, Glens Falls; John N. Beckley, president, and Charles J. Bissell, counsel, Rochester Railway Co., Rochester; Charles Cleminshaw, president, and Charles H. Smith, superintendent, Troy and Lansingburgh Railroad Co., Troy; T. R. Taltavall, *Street Railway News*; T. C. Martin, THE ELECTRICAL ENGINEER; James H. McGraw and C. B. Fairchild, *Street Railway Journal*; M. J. Sullivan and E. S. Reynolds, *Street Railway Gazette*; F. L. Kenfield, *Street Railway Review*; and N. D, Webster, *Electrical World*; H. C. Evans, Johnson Company; J. A. Hanna, McGuire Truck Company; W. F. D. Crane, W. H. Johns Mfg. Co.; D. W. Pugh, John Stephenson Co.; W. J. Clark, A. Lewis, and Prof. Feary, General Electric Company; W. H. Delaney, Royaline Mfg. Co.; W. S. Silver, Graduated Car Spring Co.; F. D. Russell and E. Packer, Rochester Car Wheel Co.; C. S. Merrill, Engineering Equipment Co.; G. N. McKibben, Reed & McKibben; Elmer Morris, Thomson-Houston Co.; J. E. Wallace, Smith & Wallace; A. R. Cook, Q. & C. Co.; J. F. Ostrom, Pennsylvania Steel Co.; Frank R. Ford, Short Electric Railway Co.; Willard S. Brown, American Casualty and Insurance Co.; John Patterson, Taylor Truck Co.; Frank A. Magee, The E. S. Greeley & Co.; J. H. Jones, West Troy, and Louis Pfingst, Boston.

Mr. John N. Beckley, of Rochester, president, made the following address:

PRESIDENT'S ADDRESS.

Gentlemen.—The year past has been without special incident, so far as the street railroad interests of the State are concerned. I shall take your time but a few moments in giving a brief summary of the record of the year, and in calling your attention to a few practical matters.

Many members of the Association feared that the street railroad interests would be subjected to uncalled-for attacks on the part of the legislature at its late session, and much apprehension was felt that unjust and hostile legislation might be successful in impairing the value and usefulness of street railroad properties throughout the State. The Executive Committee of this Association took early action, looking to the protection of our common interests. The report of the work done by the committee in this regard, will, I am sure meet your approval. The success which has attended the efforts put forth is evident to every member of the Association. No bill striking street railroad interests, and no bill which injuriously affected street railroad interests became a law. The obligation of protecting the properties which we are called upon to manage against adverse and iniquitous legislation is often lost sight of. Certain of our brethren seem to rely upon the success of efforts which they trust will be put forth by others who, perhaps, have no larger interests to protect than have they.

The most important function of a State street railroad association is to furnish information to the members of the legislature as to the needs of street railroad companies, and to combat before legislative committees, and in personal intercourse with senators and assemblymen the erroneous propositions which are often advanced without adequate knowledge of the condition of things. A great majority of the members of our legislature are honest men, who, when informed of the facts will act intelligently without injury to any legitimate industry or business. There always have been and there always will be others in every legislative body, who take advantage of every opportunity which ingenuity can suggest, to strike corporations by the medium of unjust and hostile legislation. Thus far, the street railroad companies of the State have not been injured by unwise or dishonest legislation. But immunity cannot always be secured, except as the result of diligent and intelligent effort on the part of the street railroad companies themselves. A fair and intelligent presentation of the facts as they exist, made at the proper time, I believe will always protect the interests with which we are identified; but such presentation ought to be made by the representative of this Association, and such representative ought to stand for every street railroad corporation in the State.

I trust the time will very soon come when every street railroad company in this Commonwealth will not only have its name enrolled on the books of this Association, but will be as well an active, earnest and enthusiastic member. Our interests are common, our efforts should be united.

During the past year much progress has been made in the education of the people of the larger cities of the State upon the subject of the "Trolley System" of propelling street cars. Even in the city of New York, where a year ago it seemed electric cars could never be operated, because of the intense and unreasonable prejudice of the people, franchises are being obtained, and there is every reason to believe that the old-fashioned, slow-moving and nuisance-causing horse car system of that great and prosperous city, will soon give place on all the lines to the modern systems of propulsion by electricity or cable.

Our Brooklyn friends have carried on their campaign of education with skill and unceasing effort, and the complete success of such effort seems now to be assured. So, throughout the State, until as error, ignorance and hostile interests are cleared away, the people of every community are coming to realize that they live in the last decade, and not in the middle of the 19th century. The improvements which have been made in electric and cable railroad appliances, machinery and construction, may be said to have kept pace with the demand for the same. The electric motor of to-day represents a great advance over the electric motor of last year, and the cable roads under construction in the city of New York represent the cable system at its best.

We shall have the pleasure and the honor to-day of listening to papers from two gentlemen, each of whom is in the front rank of his profession, and from them we shall learn what science, skill and experience have done in perfecting the two systems of street car propulsion, which are doing so much to make life the more worth living in the cities of our State.

Street railroad men are learning that in the management of our properties it pays to be liberal. I do not mean that it is wise to be extravagant, or reckless, or improvident in the management of such properties, but that a broad and progressive policy, which furnishes to the people increased facilities for travel, adds to the net income to be derived from the operation of street railroads. The public, as most of us have come to know, are quick to appreciate improvements made, and as quick to respond with their nickels to the effort of a company to intelligently and efficiently serve them.

It seems to me wise and in accordance with the best business principles, to keep a little in advance of the reasonable demands of the people, with reference to improvements, additions and extensions. I do not mean that a company should heed the request or demand of a hundred families to extend a line where it will require 1,000 families to support that line when extended. But constructing an extension somewhat, perhaps, in advance of the time, when such extension will pay operating expenses, is, in my opinion, as a rule, the wise thing for a railroad company to do. The same principle obtains as to number of the cars to be run on each line, and as to other improvements and betterments of the system. We depend upon the people for our patronage and every street railroad man knows that a good feeling on the part of the people towards the company which serves them, adds to the receipts of the line, makes it easier to obtain needed concessions from city governments, as well as from individuals, and prevents the granting of franchises on parallel lines to competing companies where, perhaps, only one line can be made a commercial success.

While upon this subject of liberality of treatment on the part of railroad companies, I desire to call your attention to the advisability from a business standpoint of adopting, whenever local conditions will warrant, a transfer system. It seems to railroad companies who now obtain two fares from passengers, who desire to go from one part of the city to another by means of the cars on two lines, that the income of the company must necessarily be decreased if passengers are carried for a single fare of five cents.

After a careful study of this whole question, we decided at Rochester to introduce a transfer system, under which a passenger can ride from any point in that city reached by the lines of the Rochester Railway Company to any other point reached by said lines for a single fare. We commenced giving transfers on this plan on the 5th day of October last. We provided reasonable restrictions and necessary conditions. The experiment has proved an undoubted success, not only from the standpoint of the passenger but from the point of view of the company as well. There is no question but that the receipts of the company have been materially increased by the adoption and use of the transfer system. Perhaps the location of lines and other local conditions prevailing in other cities of the State may prevent the successful introduction of a transfer system. But I thought it might be of interest to members of the Association to know of the pronounced financial success of the undertaking, so far as the Rochester Railway Company is concerned.

Until March 1st the conductors and motormen of the Rochester Railway Company were paid the same wages as were formerly paid to conductors and drivers of horse cars. We very soon found after commencing operating electric cars, that we required men of higher capacity to perform the duties of motormen and conductors than seemed to be necessary with the old system. It seemed to us that as the duties of the positions which the men held under the new system were more onerous and exacting, and as it required more judgment and skill to properly handle electric cars, the men should be paid a somewhat higher compensation than they had before received. Therefore, the company, before the men themselves made any request for an increase of wages, advanced such wages. The action of the company gave, of course, great satisfaction to the men, and the result has been very beneficial, so far as the company itself is concerned. It has been found that while the item "wages of employees" has been materially increased, the cost of operating the road per mile has in fact been diminished. This is accounted for in the fact that the men are more attentive to duty than before and more careful in the handling of cars; in greater freedom from accidents and in the material lessening in the cost of maintenance.

I am satisfied that the management of many street railroad corporations, where electricity is the motive power, have not as yet given sufficient attention to the thorough instruction of their motormen as well as conductors, as to the function of each part of the motor and as to the proper thing to be done by the motorman and conductor when trouble develops while the car is in service on the line.

Some weeks since I had occasion while riding on an electric car in a city of another State, to ask the motorman some questions about the motors he was running. I found he did not know whether the motors were Thomson-Houston, Westinghouse, Edison or Short. He did not know whether they were double or single reduction. He did not even know whether he had under his car body one or two motors. I asked him what he did in case he had any trouble on the line? He said, "If the motor don't work I wait until another car comes along and pushes me in." I found that this motorman had been for nearly nine months in regular service as motorman in that city. This motorman knew enough to turn on and turn off the current, and to set and loosen the brakes. This, of course, is an extreme case, but it illustrates the principle. My own judgment is, based upon some experience, that too much pains cannot be taken to thoroughly instruct the motorman as well as the conductor, so that each will know the cause of trouble when trouble develops in either of the motors in service.

The plan the company with which I am connected has adopted is to select from among the motormen one of the men who is pronounced by the master mechanic, the electrician, and the superintendent, the best posted as to the construction and use of a motor and make such man, for the time being, instructor of motormen on cars in actual service. This instructor rides with motorman after motorman, observes the manner in which he handles his car under all conditions and gives detailed instruction as to exactly what to do whenever trouble of the usual sort develops. The instructor spends from half a day to three days with each man until he pronounces him in every way qualified to run a car on every portion of the line and to do that which needs to be done when trouble develops.

I might call your attention to many other matters of practical interest if occasion seemed to call for further statement. It is perhaps presuming in me, to say what I have said, addressing as I am many who have had more experience than I. My only object in calling your attention to the matters I have referred to, is to make some suggestions which may be of value to some who have had less experience than I have, brief and limited though that experience may be.

REPORT OF EXECUTIVE COMMITTEE.

The report of the executive committee stated that the Association had twenty companies in its first class of membership and five in the new second class. It stated that there had been no strikes during the year, and that the outlook was an encouraging one. As to electric traction, it said: "Electricity has been booming in this State since we last met. Brooklyn, fortunately for its citizens, will soon be blessed with the overhead system on a scale nowhere equaled in the world; the very best construction both for track and overhead work having been adopted throughout the city. When fully developed to successful operation in that city, the system will bring about the condition of things throughout the country by the substitution of electricity for horses, set forth in the advertisement of a famous patent medicine, of which it is declared the 'children cry for it.' Already some of the leading dailies of New York City are beginning to change their hitherto insane abuse of the so-called 'deadly trolley,' that has never yet killed one human being; and they will soon be tumbling over one another in their enthusiastic advocacy of a system regarding which they have finally decided to learn something; and no longer to depend upon their imagination for their facts. Whatever recent improvements with manifest merit have been made in the electric system will be hailed with delight by those interested in this form of motive power."

The report was signed by Daniel F. Lewis, John N. Beckley, C. Cleminshaw and W. J. Richardson.

Mr. C. J. Bissell made an interesting report of his work as counsel in watching legislation at Albany.

It was suggested by Mr. Lewis, that the Association would be stronger if the smaller companies came in, and if the supply men would help in various ways. The suggestion was acted on later in the day.

The paper on "Cable Traction," expected from Mr. G. W. McNulty, engineer of the Broadway road, New York, was not presented, as the road is not yet running by cable.

Mr. L. H. McIntire, the engineer of the Union Co. of New York, then read the

REPORT OF COMMITTEE ON RECENT IMPROVEMENTS IN ELECTRIC TRACTION.

We understand that anything which tends to an increase of reliability or economy of operation of an electric railway is an improvement; and it is with the intention of bringing before you in a brief manner the results of my experience and observation during the past year upon these points that this article has been written.

As you, of course, know, electric systems as first constructed, were built on altogether too light a plan, and the increasing tendency year by year has been, and is, for heavier and more solid construction in every department, but particularly in the way of track and station equipments. It has been well said that no new departure is ever perfect at the beginning, and no one realizes this more than he who has watched the development of electric traction during the last few years.

The storage battery has made but little progress during the past year, and is not likely to cut much of a figure in electric traction until it is able to make a better showing, financially, than it has in the past.

It may seem strange that the management of roads, even at present operated by horses, cannot see that a change of some kind must come soon owing to the great cry for rapid transit; and yet I know of roads at present being laid with flat centre-bearing rails on stringers in streets being newly paved. I do not mention this as an "improvement," but simply to show that what may be regarded as an improvement by some would be called simply a makeshift or temporary piece of work by others.

The general tendency of the times to consolidate all common interests under one management is showing its effects in electric traction, more now than ever, and scarcely a week passes that we do not hear of some syndicate obtaining control of some horse-road, and the information usually ends with the statement that "it is intended to equip all the lines with electricity." From many points of view this is an improvement and a marked one.

TRACK.

The improvement in track construction has been very great, and although many expensive errors have been made, we ought, on the whole, to feel satisfied with the progress.

The early forms of track construction were too light and soon went to pieces; but during the past year heavier rails have been rolled and better joint plates made, so that it is possible to keep the road-bed in perfect line and surface. This improvement has been a great help to the electric equipment and has reduced the cost of maintenance. As the cost of laying tracks is about the same, whether light or heavy, it is economy to put in only the best.

Now on the question of what constitutes the best form of track, there is considerable variance of opinion. My experience and observation has convinced me that the deep girder rail, about nine inches high, spiked directly to the ties, is the best form for paved streets, and in dirt or Macadam streets, a six-inch girder rail laid in the same manner. In the country and where the local authorities are willing, I would lay a T-rail, spiked directly to the ties.

The weakest place in all forms of track construction is at the joint. Every manufacturer of rails, and many of the railroad companies, have tried to overcome this trouble. There are probably as many patents upon rail joints as upon car couplers, and most of them about as impracticable. Up to the present time there has been nothing brought out which surpasses a properly designed "fish plate."

While speaking of track construction, it might be well to call attention to the bonding of rails for the return circuit. Many forms have been used, and some of them are still in operation. I believe that a No. 0 copper bond wire long enough to connect with the web of the rail on each end of the fish plate is the best plan, and then grounding the whole system at frequent intervals, and abandon the supplementary wire which it has been the custom to use with the common form of bonding.

ELECTRIC EQUIPMENT.

Probably the greatest advance in any particular line has been in the matter of armatures for motors and dynamos. I consider that the introduction of the "iron clad" type will do more towards reducing the bill for repairs in that direction than any other one thing that has been introduced during the year. The electric companies have all, I believe, now adopted this form as their standard, and all roads that have tried them will, I think, agree with me that, for simplicity, ease of repair and ability to stand the hard usage they receive, they stand at the head.

In the manner of controlling the motors most of the companies still use the time-honored rheostat; although I believe one company are endeavoring to introduce a new type of controller, which they will, doubtless, be happy to explain at a later date.

Many roads, acting under a misapprehension of the requirements, started off with motors too small for the work, and endless trouble has been the result. Some new classification should be adopted by the electrical companies for designating the power of their motors, as the present "office classification" does not afford a proper understanding of its capacity, and the "horse power" term is but little better, depending on so many limiting conditions. A more satisfactory way would be to specify the number of pounds the motor can pull at different speeds, with the maximum current for which it is designed.

TRUCKS.

The first car trucks employed in electrical work were of the pedestal form; that is, the trucks were fastened to the car body and oscillated with the car. The motors, of course, had to be suspended from the car body, and the result was that the grinding of the gears was transmitted through the whole car; also, the oscillation of the car body caused the motors to correspondingly rise and fall. This was very undesirable, and it was soon found necessary to adopt the post form, in which the truck was complete in itself and the motors supported directly on the frame of the truck. The body was connected with the truck only by springs, thus being entirely free from the jolts and pounding of the truck.

In this form slight spiral springs were first used, the same as in the previous styles, but it was soon found that the high-speed attained caused the body to oscillate to such a degree that it became very objectionable, and the different builders then modified their trucks by extending the side bars beyond the axle boxes a sufficient distance to allow an auxiliary spring to be added at each end. For this auxiliary support, coil and elliptical springs have been used, both forms with marked success, and it is now possible to carry a car body 28 feet over all, practically without oscillation. This last modification has been a very great improvement, and has settled the long car question on most street railways. I mean by this that but very few double-truck cars will be used, though, of course, there are places where two trucks can be used to advantage, and in such places they will still be employed. But where we are able to carry nearly as many people on four wheels as on eight, and to apply the power equally on each axle, so that there is no possibility of lack of traction, there can be no gain to the railroad company in using eight wheels.

CARS.

The car bodies first employed were of the same style and proportions as those used for horse roads, and were not properly designed for electrical purposes; first, the framing of the roof was too weak and would not support the trolley board properly; second, the framing of the floor was not adapted for the use to which the cars were put; for not only was the framing too weak, but it was also not well planned for putting in the trap doors which are required in order to inspect the machinery underneath the floor.

The car which it seems to me is best adapted for the present service is one 18 feet 6 inches long inside, with platforms 3 feet 6 inches long. The rafters should be strengthened with steel plates and the framing throughout should be heavier.

The coloring of the cars and the necessary signs are attracting considerable attention from the different railway companies, but up to the present time I do not think any concerted action has been taken. For my part, I believe that all of the cars on a system should be painted the same color; that is to say, each separate line should not have a distinct color, but signs should be used to designate the different routes; preferably by means of the well-known reversible sign on the top of the car both at the sides and front. At night the lines might be distinguished by the color of the ventilator glass, which would in each case be the same as the ground color of the reversible sign.

OVERHEAD CONSTRUCTION.

There has been a general improvement in all parts of the overhead material. We are using stiffer poles, stronger span wires, better trolley wire insulators and handsomer curve fittings; so that the general appearance of the system is much pleasanter. The quality of insulation now in general use is far superior to what we had two years ago, and as double insulation is now employed on the span wires, very little trouble from leakage is experienced.

The method of feeding the line is a very important matter and should receive careful attention. The best arrangement is to divide the system into several sections, so that in case of trouble along any portion of the line, such as fire, etc., that section can be cut out and the balance of the system run as usual.

THE POWER STATION.

This may be rightly called the heart of any electric system. The trolley and feeder wires form the arteries, the rails and return wires the veins, and the cars the capillaries connecting them. The Biblical injunction to "Guard thy heart with all diligence, for out of it are the issues of life," would certainly seem applicable to the station. The chief element to be considered should be reliability, and after that economy. Just what means shall be used to attain this end seems so far to have been a disputed matter, as shown by the stations now in operation, which contain almost every conceivable device, good, bad and indifferent; all shapes, sizes and descriptions of engines, boilers and dynamos. Many designers of stations—if some of them can be said to have been designed at all—seem to have gone at their task utterly regardless of the future and oblivious to the experiences of the past. However, through it all I can say that a very marked improvement is observable lately. The designers of stations are learning wisdom from their past experiences, and the makers of apparatus are more alive to the requirements of the system, and better material and workmanship can be had where required.

The recent introduction of large multipolar dynamos has brought about a change in station arrangements not heretofore obtainable, and in all large stations now being built countershafting is dispensed with entirely, and the general tendency is towards reduction of parts, which in turn means simplicity. It is very probable that we have reached now a form of station that will be fairly permanent, and the main point in the future will be the size of the units. For medium size stations engines with releasing valve gear belted direct to a multipolar dynamo will be the best where the price of land is not excessive, and direct-coupled engines and dynamos for larger stations. To my knowledge there have been no comparative tests made as to the economy of the various types of stations, although all reasoning would point to those latest types as being by far the most economical.

There has been heretofore too much taken for granted or assumed in electrical work, and the rapid growth of the business has called into it many who were totally unqualified for the positions which they obtained. I attribute much of the unsatisfactory work in the past to this course, but am happy to note that the great majority of these are passing into the background, and their places are being filled with men of good judgment and mechanical resources.

Respectfully submitted,
L. H. McIntire,
Committee.

At the close of Mr. McIntire's report, the following set of resolutions was offered by Mr. Lewis, and carried unanimously:

Whereas, The Street Railway Association of the State of New York, assembled at Saratoga Springs for its Tenth Annual Meeting, has learned that the Union Railway Company of New York has put in operation this week the first electric trolley cars within the city of New York;

Resolved, That the Association congratulates the company and the public of the greatest city in the Union upon this adoption of the latest and most improved method of street railway traction;

Resolved, That the Association earnestly deprecates the opposition manifested against the trolley system in various quarters, as being founded upon neither reason nor fact, and as being contrary to the best interests of any community seeking rapid transit facilities and suburban homes for a growing population; and

Resolved, That the Association hereby tenders to Mr. L. H. McIntire, engineer of the Union Company, its thanks for his able address on the work already accomplished in New York, and its wishes for the development in the metropolis of the system thus inaugurated.

A brisk discussion then ensued on Mr. McIntire's paper, in which Messrs. McNamara, Powers, Cleminshaw, Beckley and others took part, the points touched upon being size of units, depth and weight of rail, distinguishing cars at night, joints between rails, headlights, etc. Opinions differed as to rails and joints, but it was urged that deep rails could neglect provision for expansion as they went well into the earth and radiated the heat. Hence the rails could be put solid together. At Glens Falls, even with a 40-pound rail, Mr. Powers had adopted the solid practice of the New York Central Company as seen at Poughkeepsie; and nobody could count the joints on his road. As to distinguishing cars at night, the practice varied. At Troy, Mr. Cleminshaw had bull's eyes four times as large as usual. Mr. McNamara had tried colored rims an inch wide around the headlight. It seemed to be the opinion that now so many cars are under one management, and the cars are of uniform color, a better means of telling the cars quickly at night was needed.

Messrs. Cleminshaw, Lewis and McNamara were appointed a committee on nomination, and proposed the following names, and the gentlemen were thereupon elected: President, C. Densmore Wyman, New York; vice-president, Daniel B. Hasbrouck, New York; 2d vice-president, J. A. Powers, Glens Falls; secretary and treasurer, W. J. Richardson, Brooklyn; executive committee, D. F. Lewis, Brooklyn; John N. Beckley, Rochester; John W. McNamara, Albany.

Mr. Lewis offered an amendment to the by-laws, increasing the annual dues of members in the first-class to $50, as recommended by the executive committee, which was adopted.

The meeting then adjourned, to meet in Rochester, the third Tuesday in September, 1893.

In the afternoon those in attendance at the meeting were invited by the Union Railway Company, of Saratoga, to participate in a trip on the electric road to Saratoga Lake. The ride was enjoyed by all.

MATERIAL MEN'S AUXILIARY ASSOCIATION.

In accordance with a suggestion made in the Convention that a Material Men's Auxiliary Association should be formed, the material men present met on the U. S. Hotel piazza at 1.45 p. m.

On motion, H. C. Evans acted as chairman and appointed John

F. Ostrom, W. J. Clark and J. H. McGraw a committee to report organization and name and to name officers for ensuing year. After a trip over the line of the Union Railway Company, of Saratoga, the material men met in parlor 8, U. S. Hotel, at 5 p. m. and received the committee's report as follows:

The name of this organization shall be "Association of Dealers in Street Railway Materials, of the State of New York."

The object of the association shall be to make possible concerted action on any matters that may affect the business of its members and to aid the New York State Street Railway Association in its efforts to prevent any legislation which it may consider hostile to the interests of the street railways of the State of New York, as well as to aid it in promoting beneficial legislation.

The officers of the association shall be a president, two or more vice-presidents and a secretary and treasurer, to be elected annually.

The work of the association shall be performed by the officers and committees as follows:

A. An executive committee of nine members, to be elected annually.

B. A legislative committee of five members, to be appointed by the president annually.

The dues of the association shall be: Initiation dues, $5.00; annual dues, $5.00.

This association shall hold an annual meeting on the date and at the place of the annual meeting of the New York State Street Railway Association and other meetings at such time and place as may be called for by the president.

Membership.

Any individual, firm or corporation dealing in street railway materials, any engineer, individual, firm or corporation engaged in street railway construction work, or any trade paper published in the interest of the street railway profession, may become a member by registering with the secretary and treasurer and paying the initiation fee and annual dues.

Each member to carry one vote.

Your committee would suggest the following as officers and committee to serve for the ensuing year:

President, Wm. J. Clark, New York; vice-presidents, Jno. W. Fowler, Brooklyn; D. W. Pugh, New York; John Jones, E. J. Gilbert, Troy, N. Y.; secretary and treasurer, C. E. Stump, New York. Executive committee, W. J. Clark, New York; H. C. Evans, New York; Jno. A. Wood, New York; Wm. S. Silver, New York; C. E. Stump, New York; T. C. Martin, New York; S. W. Baldwin, New York; F. D. Russell, Rochester; D. C. Breckenridge, New York.

It would also suggest that the president be authorized to appoint a committee to perfect a constitution and by-laws as embodied in the above.

Respectfully submitted,
(Signed) JOHN F. OSTROM, Chairman.

After some discussion, the report of the committee was adopted and the officers declared elected. It was decided that only residents of New York State be eligible as officers or committeemen, and that the constitution contain such a provision; also resolved that the president be appointed a committee of one to advise with the New York State Street Railway Association and advise it of the action of the meeting.

Society and Club Notes.

AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.

THE above association have now issued their programme, mentioned in our last issue, for their annual meeting at the New York Academy of Medicine, Oct. 4, 5 and 6. The list of papers is a long one and very interesting from the medical standpoint. Among the electrical contributors are Prof. Houston and Messrs. A. E. Kennelly and J. J. Carty. Committees are to report on standard coils and meters. On Oct. 4, after the evening meeting, the members will visit the Electric Club. On October 5 there will be a reception in the evening, with a phonograph lecture by Dr. J. Mount Bleyer. On Thursday afternoon the members will visit the Edison laboratory and see some physiological experiments with magnetism. During the convention an exhibit of electro-medical apparatus will be made by T. A. Edison, J. H. Bunnell & Co., Waite & Bartlett, The Galvano Faradic Co., W. F. Ford, Otto Flemming, McIntosh Co., Law Battery Co., etc.

A ST. LOUIS ELECTRIC CLUB.

IN view of the meeting of the National Electric Light Association in St. Louis next February, the electrical people of that city have taken steps to organize an electric club, which will be ready to extend its hospitalities at that time, and will be made a permanent society as soon thereafter as possible. A committee is actively working on the matter now.

Inventors' Record.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED SEPT. 13, 1892.

Alarms and Signals:—

Adjustable Thermostat, M. D. Compton, Newark, N. J., 482,420. Filed Nov. 21, 1891.

Employs electromagnets brought into circuit by the motion of the thermostat bar and serving to hold the bar in firm contact.

Rudder Indicator C. Cory, New York, 482,421. Filed Nov. 24, 1891.

An electrical device for indicating the position of the rudder of a vessel.

Burglar Alarm, H. T. Wilson, Louisville, Ky., 482,464. Filed March 4, 1892.

A contact device adapted for attachment to door or window casings without the necessity of channeling the casings.

Distribution:—

Means for Controlling Electric Generation, T. A. Edison, Menlo Park, N. J., 482,549. Filed March 12, 1881.

Claim follows:

The combination, with a minor consumption circuit with one or more magnetoelectric machines connected therewith, an exciting machine supplying the field circuit of the main machine or machines, means for varying the speed of the exciting machine independently of the main machine or machines, and a suitable electrical indicator indicating the condition of the main circuit.

Dynamos and Motors:—

Ventilating Armature for Dynamo-Electric Machines, E. Thomson, Lynn, Mass., 482,397. Filed April 2, 1885.

Designed especially for application to hollow armatures or armature carriers. Employs a blower. The armature shaft may be hollow.

Galvanic and Thermo-Electric Batteries:—

Galvanic Battery, T. T. Eckert, New York, 482,425. Filed May 16, 1892.

Claim 3 follows:

In a galvanic battery, a zinc electrode formed of perforated zinc plates and separate zinc pins or screws, said pins or screws being employed to fasten adjoining plates together and to suspend the composite electrode from a cross-bar or other support above the cell.

Voltaic Pile, W. E. Washburn, Cedar Rapids, Iowa, 482,444. Filed June 14, 1892.

Adapted in form and structure for convenient use in therapeutics. The construction is such that the entire pile may be immersed in an exciting fluid.

Heating:—

Electrical Furnace, J. Parker, Newbridge, England, 482,586. Filed July 5, 1890.

Employs a strip or bar of conducting material on each side of a furnace, each strip having two sets or series of holes corresponding to similar openings in the walls of the furnace, one set of holes being above the other set and fitted with metallic sockets holding stationary electrodes. There are also adjustable metallic or carbon rods fitted in the lower set of holes for striking the arc when commencing to work the furnace.

Lamps and Appurtenances:—

Electric Light Fixture, E. R Crolius, Chicago, Ill., 482,339. Filed Jan. 4, 1892.

Relates to a fixture joint.

Electric Arc Lamp, H. H. Cutler, Waltham, Mass., 482,435. Filed June 25, 1891.

Relates to feed mechanism for a lamp adapted for use either on a constant potential or a constant current circuit.

Line-Wire Tightening Device for Electric Lamp Supports, C. A. Pfluger, Chicago, Ill., 482,486. Filed May 3, 1892.

Employs a rotary binding post and means for holding the post against the strain of a tightened wire.

Clamp for Arc Lamp Carbons, A. Weber, Schenectady, N. Y., 482,535. Filed Nov. 4, 1891.

Device to facilitate the work of the lamp trimmer.

Electric Arc Lamp, H. H. Bigland & J. Burns, Newcastle-on-Tyne, Eng., 482,568. Filed April 20, 1892.

Regulating apparatus, having a twist-rod, a movable carbon-holder controlled thereby, means for lifting said twist-rod and holder simultaneously, and means for imparting a rotary motion to the twist-rod at a determinate point of its lift, as and for the purpose set forth.

Miscellaneous:—

Safety Device for Electric Circuits, L. B. Atkinson, London, Eng., 482,433 Filed Sept. 12, 1891.

Employs a subsidiary circuit (shunt) protected by a fuse or cutout operating with less than the normal current carried by the main conductor.

Electrical Apparatus, L. G. Woolley, Grand Rapids, Mich., 483,668. Filed June 6, 1892.

An apparatus designed to permit the employment of current for alarm purposes and for medical purposes at one and the same time.

Railways and Appliances:—

Inclosed Conductor for Electric Railways, G. A. Dupuis, Detroit, Mich., 482,348. Filed May 16, 1891.

Employs an insulated conductor and conducting pistons or plungers reaching through the insulation at definite intervals, and friction rollers on the outer end of the pistons or plungers, the latter actuated by a traveler.

Railway Crossing Protector, R. J. M. Danley, Columbus, Ohio, 482,422, Filed March 2, 1892.

For sounding an alarm or closing a gate at a highway crossing. Employs two sets of relays operating for trains coming in either direction.

Railway Crossing Protector, R. J. M. Danley, Columbus, Ohio, 482,423. Filed April 20, 1892.

Amplification of the above.

Underground Trolley, J. Fischer, Cleveland, Ohio, 482,506. Filed March 5, 1892.

Employs an anti-friction sleeve fitting loosely on the trolley arms for protecting the latter from wear in the conduit slot.

Railway Time-Signal, W. Scott, Hot Springs, S. D., 482,699. Filed May 13, 1892.

For signaling the time of passing trains.

Electric Locomotive, W. H. Soley & W. Washington Perkins, Philadelphia, Pa., 482,594. Filed Jan. 7, 1892.

Designed to permit the car to run at a high or low rate of speed while maintaining the motor at a contant speed.

Switches and Cut-Outs:—

Automatic Electric Cut-Out, C. O. Mailloux, New York, 482,374. Filed Sept. 9, 1890.

Relates to cut-outs in which the switch is normally locked by a catch or detent operated by an electromagnet.

Telegraph:—

Telegraph Relay, W. Maver, Jr., New York, 482,440. Filed July 18, 1891.

A quick-acting relay. Claim 2 follows: In a telegraph system, the combination of a main-line conductor, relatively movable coils in series with each other and in a circuit with the main-line conductor, two portions of each coil being at an angle to two portions of the other and the remaining portions of each coil being parallel to one another, an independent or local line conductor, and a circuit-closer in circuit therewith and controlled by that coil which is movable.

Letters to the Editor.

GOVERNING WATER WHEELS.

In your issue of Sept. 14, "Mechanical Engineer" propounds a question upon the governing of water wheels. He has probably been urged to this by experience in operating them, which I do not think is peculiar to himself.

I desire to take issue with him on his suggestion of allowing the wheels to run at full gate always, and absorb what power is not required upon the electrical circuits by electrical means in the stations. It does not seem right to use and pay for the means of converting power in the basement for the sake of reconverting it to a useless end, and I think it is neither necessary nor expedient.

The fact of there being plenty of water may apply to a few large plants, but certainly not to the much larger number of smaller plants. I believe a very large majority of the water powers at present in use need all the water they can get at some periods. These powers are subject to dry seasons, hard winters and very often to limited rights of flowage, and a small reservoir capacity above the dam. In designing a central station, one of the most important features to be attained is continuous service, and therefore the above conditions cannot be ignored.

The method suggested by your correspondent, or a similar one, has been used and with some success, according to an issue of The Electrical Engineer of some months back, but two blacks do not make one white, and I wish to make some suggestions.

1. The fly-wheel is an old friend whose usefulness is in no way impaired at present, although some think that electricity should and will eventually do everything. Taking a railroad circuit, for instance, the changes of load are great, sudden, and very frequent. Under these conditions I think a fly-wheel may be designed to be of considerable service.

2. It is possible to build a turbine with arrangements for controlling the water supply, which, instead of being a "gate," may more nearly approach a "valve." This will incur expense and is scarcely possible with some types of turbines. The valve should have a large number of small openings requiring only a small motion to control it. This motion may be derived by mechanical means from variations of speed, or directly from the electrical circuit attached to the power.

Either of these methods may be used in conjunction with the fly-wheel, and will entail less expense than the absorption dynamo suggested by your correspondent, and will save a large amount of water, which is of considerable importance to a large number of plants, as already pointed out.

J. A. Cross.

New York, Sept. 19, 1892.

ACME STORAGE BATTERY MFG. CO.

This company which is incorporated under the laws of the State of New Jersey, with a capital stock of $5,000,000, has been organized for the manufacture of cells for electric storage batteries and motors for traction work, and of storage batteries for stationary and lighting purposes. It has acquired the patents on storage ba teries just issued to Messrs. Patrick Kennedy and Chas. J. Diss, of Brooklyn. These batteries are employed on the storage car on the Ninth Avenue surface road in this city, and are described on page 293 of this issue. The officers of the company are, G. C. Warner, president; Wm. H. Fletcher, vice-president; G. S. Stringfield, treasurer; C. T. Griffith, secretary; and W. M. McDougal, general manager. The company's offices are situated in the Columbia Building, 29 Broadway, New York City, and in the Fuller Building, Jersey City. Preparations are now actively going forward for the placing of the new storage cells on the market, and we understand that negotiations for the equipment of two roads, one in the East and one in Chicago, are now under way.

Liggett, Turbayne & Co., No. 54 Grand River avenue, Detroit, Mich., have equipped the Michigan Forge & Iron Company's plant with Turbayne arc lamps.

TRADE NOTES AND NOVELTIES

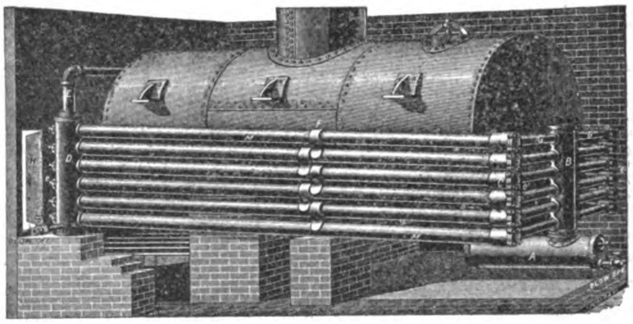
AND MECHANICAL DEPARTMENT.

People rarely, if ever, buy articles that are not advertised.

THE SLOANE IMPROVED STEAM GENERATOR AND BOILER AUXILIARY.

The accompanying engraving illustrates the latest type of steam generator design by Mr. G. W. Sloane, of 343 Manhattan avenue, Brooklyn, N. Y. Its construction is based on the same principle as the older type but one of the main features of improvement consists in placing hand holes opposite each end of every tube for facility of internal examination and cleaning out. The tubes are of the best quality American lap welded, four inches in diameter, and are inclined upwardly one-half inch to the foot, to allow of easy ingress of steam into the boiler.

These tubes are expanded in the usual manner into the drums D which are placed at the front of the boiler, one on each side, and into the heads C at the back of the boiler. Heads C are provided with heavy flanged and faced caps *e e'*, and the drums D are provided with suitable hand holes *e*, plates, guards and blow-off cocks. A 5-inch pipe O supplies the generator with water from the boiler. This flows through the mud drum A and through a 5-inch connection to drum B, thence through the pipes G (which are lap welded 2-inch internal diameter and have right and left hand threads) into heads C and tubes M through pipe E into the boiler. Pipe E varies in size from three to four inches in proportion to size of generator and boiler. Pipes G provide for any unequal expansion of tubes M. Openings are made in the front provided with doors H or an equivalent covering plate to give free access to hand holes in drums D. Openings and doors are placed in the rear wall to provide access to flanged caps *e e'*. Tubes M rest on suitable cast iron supports F.



Sloane Improved Steam Generator.

The mud drum is 12 inches in diameter and made from steel five-sixteenth inch thick, and is fitted with a hand hole, plate and guard, also with a 2-inch blow-off cock for the purpose of blowing off the scale which is carried into the drum by the circulation constantly maintained through the generator and boiler. The circulation through the mud drum being only one-sixth as rapid as in the 5-inch connections, retains the scale and sediment until the cock is opened to blow it off.

The economy both as a fuel economizer and in increased power developed is attested by many testimonials in the hands of the inventor.

THE RIES REGULATING SOCKET FROM THE STATION STANDPOINT.

The following is a copy of a letter recently received by the Ries Electric Specialty Company, of Baltimore, Md., which speaks for itself:

Office of the Dover Electric Light Company,
Dover, N. J.

The Ries Electric Specialty Company,
Baltimore, Md.

Gentlem n.—Your last shipment of regulating sockets was duly received. They meet with great favor from our customers, and we expect to have some in every building that we light. They are a great convenience to the user and are a potent factor in gaining us new customers for our lights.

Yours truly,
The Dover Electric Light Company.
D. Young,
Manager.

LARGE BUSINESS OF THE KEYSTONE ELECTRIC COMPANY.

Mr. J. W. Leech, president of the Keystone Electric Co., of Erie, Pa., favors us with the following list of motors and dynamos sold by his company during the past three months. It is a very creditable exhibit for a dull summer and shows what can be done by judiciously pushing good manufactures:

Jas. H. Link, Norfolk, Va., 10 h. p. motor to run machine-shop; D. A. Fessler, Williamsport. Pa., 1 h. p. motor to run ceiling fans; Whittier Machine Co., New York, N. Y., 5 h. p. motor (reversible) to run elevator; Birdinger, Seibert & Co., Cincinnati, Ohio, 10 h. p. motor (reversible) to run printing establishment; J. H. Link, Norfolk, Va., ¼ h. p. motor (reversible); Jamestown Electric Light Co., Jamestown, 2 h. p. motor to run printing establishment; J. Page & Son, Cohoes, N. Y., 25-light incandescent dynamo to light cotton mill; Smith Crawford, Youngstown, Ohio, 10 h. p. motor to run feed mill; Youngstown Electric Light Co., Youngstown, Ohio, 1 h. p. motor to run fans; E. E. Johnson, Chicago, Ill., 3 h. p. dynamo; E. E. Johnson, Chicago, Ill., 1 h. p. motor to run triplex pump; H. M. Sutzinger, Wilkesbarre, Pa., 2 h. p. motor; A. K. Dysher, Reading, Pa., 5 h. p. motor (reversible) to run elevator; Genessee Hotel, Buffalo, N. Y., ¼ h. p. motor to run fan; Geo. Dun, Erie, Pa., ¼ h. p. motor to run ceiling fan; M. J. O'Donnell & Co., Cleveland, Ohio, 10 h. p. motor (reversible) to run passenger elevator; Youngstown Electric Light Co., Youngstown, Ohio, 1 h. p. motor to run fans; Youngstown Electric Light Co., Youngstown, Ohio, 1 h. p. motor to run fans; Youngstown Electric Light Co., Youngstown, Ohio, 2 h. p. motor to run printing establishment; E. A. Sarran & Co., Cincinnati. Ohio, ¼ h. p. motor to run fans; E. A. Sarran & Co., Cincinnati, Ohio, 2 h. p. motor; Jas Curney, Erie, Pa., ¼ h. p. motor to run fans; Jamestown Electric Light Co., Jamestown, ½ h. p. motor to run fans; E. A. Sarran & Co., Cincinnati, Ohio, ¼ h. p. motor to run fans; E. A. Sarran & Co., Cincinnati, Ohio, 3 h. p. motor; E. A. Sarran & Co., Cincinnati, Ohio, 40-light dynamo; Youngstown Electric Light Co., Youngstown, Ohio, 1 h. p. motor to run fans; Hunt & Connell, Scranton, Pa., 1 h. p. motor to run fans; Youngstown Electric Light Co., Youngstown, Ohio, 1 h. p. motor to run fans; St. Mary's Catholic Church, Erie, Pa., 1 h. p. motor to run church organ; Marshall Bros., Pittsburgh, Pa., 5 h. p. motor (reversible) to run passenger elevator; J. H. Link, Norfolk, Va., 25-light dynamo; J. H. Link, Norfolk, Va., 12-light dynamo; J. V. Yelgerhouse, Erie, Pa., ½ h. p. motor to run optician shop; E. A. Sarran & Co., Cincinnati, Ohio, ½ h. p. motor, to run fans; E. A. Sarran & Co., Cincinnati, Ohio, 3 h. p. motor to run machine shop; Buffalo Forge Co., Columbus, Ohio, 15 h. p. motor to run ventilating fan; Buffalo Forge Co., Columbus, Ohio, 15 h. p. motor to run ventilating fan; H. Ward Leonard & Co., New York, N. Y., 3 h. p. motor to run printing establishment; H. J. Reedy Elevator Co., Cincinnati, Ohio, 7½ h. p. motor (reversible) to run elevator; H. J. Reedy Elevator Co., Cincinnati, Ohio, 15 h. p. motor (reversible) to run elevator; McCreery Ventilating Co., Toledo, Ohio, 3 h. p. motor to run ventilating fan; Heat, Light and Power Co., Muncie, Ind., ½ h. p. motor to run ventilating fan; Heat, Light and Power Co., Muncie, Ind., 1 h. p. motor to run ventilating fan; Heat, Light and Power Co., Muncie, Ind., 5 h. p. motor to run printing establishment; Heat, Light and Power Co., Muncie, Ind., 5 h. p. motor to run printing establishment; Hazeltine Woolen Mills, Warren, Pa., 40-light incandescent dynamo; M. J. O'Donnell & Co., Cleveland, Ohio, 7½ h. p. motor to run elevator; E. A. Sarran & Co., Cincinnati, Ohio, ¼ h. p. motor to run fans; Baker & Handley, Cincinnati, Ohio, 40-light dynamo; Youngstown Electric Light Co., Youngstown, Ohio, 5 h. p. motor; Rothchilds Bros., Ithaca, N. Y., 1 h. p. motor to run cash carrier; Bigelow Elec. Supply Co., Lincoln, Neb., 1 h. p. motor; Stuart & Harper, Winnipeg, Manitoba, 60-light incandescent dynamo; Dunkirk Printing Co., Dunkirk, N. Y., 7½ h. p. motor to run printing establishment; Geo. F. Patterson & Co., Baltimore, Md., ¼ h. p. motor (reversible); Buffalo Forge Co., Buffalo, N. Y., 5 h. p. motor to run ventilating fan; Kirby-Carpenter Co., Menominee, Mich., 125-light incandescent dynamo to light saw mill; F. W. Bacon & Co., Erie, Pa., 40-light incandescent dynamo to light fish house; Ames & Walker, Fargo, N. Dak., 40-light incandescent dynamo to light store.

It may be noted, in explanation of several of the items above, that the company makes a specialty of its reversible motors, without rheostats, and that it enjoys remarkable success with them.

INSULLAC.

It is a noticeable fact that the progress of practical electrical science has been so rapid that the allied chemical and mechanical arts have failed to keep the pace. Especially has this been apparent in the case of insulating compounds, shellac being the only practical agent for effective work in coil and armature winding and in the multitudinous applications where insulation resistance and waterproofing is required. The following quotation from Prof. Ayrton's "Practical Electricity," is a volume in itself. "At the present day it is very difficult to buy really good shellac, the material of commerce being very much adulterated."

The fact that shellac is manufactured abroad readily explains this condition of affairs, which is still further complicated by the adulterations of the dealers. Shellac cut in grain alcohol is much superior in resistance to solution in wood alcohol, a fact which is familiar to all electrical experts.

Some months ago the Massachusetts Chemical Company, of Boston, called the attention of their chemists to this state of affairs, believing that it should be possible to produce a varnish which could be marketed at a lower price than shellac and at the same time be of uniform quality and high resistance. That their efforts have been successful in a very great degree is demonstrated by the production of an alcohol varnish of an insulation resistance nearly four times greater than that of the best grain alcohol shellacs. The Massachusetts Electrical Engineering Company is the authority by which this superiority is established.

This varnish is aptly named "Insullac" (insulating gum). It is of a beautiful transparent amber color, but to suit the public taste the manufacturers will produce it in any desired color. Its appearance when applied, method of application and rapid drying qualities are identical with those of shellac, whose place in electrical work it may entirely supersede.

Prof. Babcock, the well known Boston chemical expert and assayer, reports that a careful analysis of the new compound shows no traces of any acids injurious to any materials to which it may be applied, or any constituent in any way injurious to the health of workmen.

The fact that "Insullac" is placed upon the market at a lower price than the poorest shellacs should at once attract the attention of all users of shellacs for electrical purposes.

THE BILLINGS & SPENCER CO.

The Billings & Spencer Co. say in regard to the past year's business and present outlook: "Our business for the present year has been very satisfactory to us and in amount has far exceeded that of last year. Our trade in Billings patent commutator bars, drop forged, of either pure Lake copper or Tobin bronze, has been constantly increasing and we are now doing a large business in this line, not only with the electrical companies manufacturing dynamos and motors, but also with the street railway companies direct, who require these goods for repairs. The sales in our machinist's tool department have been very satisfactory and constantly on the increase. In the electrical line. our linemen's hand vise, combination pliers and drop forged wrenches are meeting a large demand. We consider the outlook for the coming year to be very promising and in evidence of same would state that we are at present erecting a new factory, office and shipping department. The total length of buildings will be 208 feet by 40 feet wide, two stories and basement."

QUEEN & COMPANY.

Queen & Co. of Philadelphia report steadily increasing sales of their "Magnetic Vane" ammeters and voltmeters, which instruments meet with much favor for switchboard use. They have now been on the market long enough to show real "staying" qualities, and combine a handsome appearance with accuracy and moderate prices. An entire absence of permanent magnets and other changeable parts renders them, it is claimed, constant in indication, so that recalibration is unnecessary, unless required mechanically.

Four manufacturing concerns have adopted these instruments, and install them with both light and power plants, while numerous others use them to a considerable extent. The Queen factory is taxed to its utmost capacity and every effort is being made to keep up with the demand. Descriptive circular No. 330 will be mailed by the firm, upon request.

INTERIOR CONDUIT AND INSULATION CO.

The Interior Conduit and Insulation Co. shipped over 1,000,000 feet of their insulated tubing during the month of August last, which fact best attests the popularity of their system. Among the buildings now being wired by their system in New York City, are the American Fine Arts Building, Havemeyer Office Building, Morris Office Building, Hotel Waldorf, and the residences of C. P. Huntington, Whitelaw Reid and J. Pierpont Morgan, Jr.

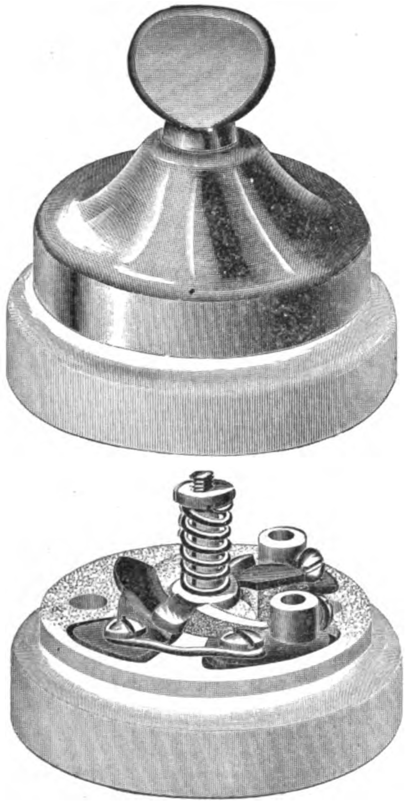
The General Electric Company has made a contract with the Merrimac Valley Street Railway Company, of Lawrence, Mass., for 15 car equipments of two each of the S. R. G. 30 type of motor. It has also contracted with the Cass Avenue Street Railway Company, of St. Louis, Mo., for 85 car equipments, each car to be equipped with two 25 h. p. motors of the W. P. type. The power plant will consist of three 800 h. p. direct-coupled dynamos.

STORAGE CARS AT A SACRIFICE.

J. C. Chamberlain & Co. of 136 Liberty street, are offering for sale the entire plant and equipment of the United Electric Traction Co., cars, engines, etc., at Marion, N. J. This equipment includes a number of railway motors of standard make, some entirely new, and others that were used but a few months; also, two 75 h. p. Straight Line Engines in perfect running order. The desire is to close out, regardless of price, this entire equipment of storage battery cars, etc., which were operated so successfully in the city of New York by the Julien Co., until litigation unfortunately brought an abrupt ending of what promised to be a most successful enterprise.

THE "IONA" SNAP SWITCH.

We illustrate in the accompanying engravings the "Iona" snap switch, which is something quite novel. It is a switch and cut-out combined, every switch being fitted with a fuse. This switch is claimed to be simpler and to have fewer parts than any other circuit breaker now made. There is nothing to wear out; it is convenient to wire, and the contacts are of soft brass, which obviates the difficulty experienced with spring clips, which lose their temper by heat and render the switch useless. The switch is made of vitrified porcelain, with nickel covers, and also in china, both plain and decorated. It is being put on the market by the Redding Electric Co., of 41 Federal street, Boston.



Figs. 1 and 2.—"Iona" Snap Switch.

THE FRINK SYSTEM FOR THE WORLD'S FAIR.

A writer in *The Collector*, a journal of art, bibliography, etc., says: "I recently mentioned the liklihood that the art section of the World's Fair at Chicago would be lighted by the Frink system of reflectors—the only system I am acquainted with which would be adequate to this important purpose. I have studied the various methods of lighting picture galleries for a number of years, and have on occasions experimented in that direction myself; and under no other system than the Frink have I found it possible to avoid those numerous drawbacks in the reflection and refraction of light by which pictures suffer so much under artificial illumination. In view of the vast preparations for the art exhibit at the Chicago Fair, therefore, it struck me as a matter of the first importance, both in justice to the exhibitors and for the benefit of the public, that the managers should give especial attention to this important feature of their galleries. I now learn that the Frink system has been finally adopted by Mr. D. H. Burnham, chief of construction of the Exposition, for use in all the seventy-eight galleries of the fine arts. The award was, moreover, made upon the tested merit of the system. Mr. James W. Ellsworth, who owns one of the finest private collections in Chicago, is a director of the Exposition, and his two private galleries have been fitted with the Frink reflectors. Their practical application, with completely successful results, led him to recommend their adoption for the department of the Exposition in which he was specially interested."

PHILADELPHIA NOTES.

The Bliss Engineering Co. have taken the agency for the District of Columbia for the Kester arc lamp for incandescent circuits, manufactured by the Kester Electric Manufacturing Co., Chicago. The Bliss Co. are wiring two halls and four large stores on G street for Mr. Geo. E. Emmons, and have just completed the wiring of Kernan's Theatre for 206 lights, which has been stated by Mr. Jas. P. Freeman, inspector of fire underwriters, to be the best-wired theatre in Washington.

The Helios Electric Co., assisted by Mr. Max Luhn, of Germany, made some very satisfactory tests, last week, with their new arc lamp, which will soon be placed upon the market. Mr. Luhn, the inventor of the Helios lamp, and who for the past nine years has acted as electrical engineer for the Helios Co., Cologne-Ehrenfeld, Germany, states that during the two years the lamp has been in use 30,000 have been sold in Germany, England and France.

Mr. C. J. Swift, general manager of the Duplex Electric Co., of Corry, Pa., was in town last week and closed a contract with Messrs. Hoopes & Townsend for a large Duplex motor and other electrical apparatus to be placed in the factory at Broad and Buttonwood streets. The Duplex Co. are running their factory night and day until an additional new factory, now under way, is ready for occupancy.

Mr. George Herbert Condict, the electrical engineer, has just returned from Europe where he has been making a study of electrical work. He has paid special attention to storage traction, in which he has had considerable experience, and he expresses himself as thoroughly satisfied in regard to the bright outlook of that industry.

The Sussex Independent, published at Deckerstown, N. J., gave a very flattering account last week of their new central station recently installed by the Heisler Electric Co., of this city. The installation has been under the supervision of Mr. John W. Carr, of Hackettstown, N. J., special agent for the Heisler Co.

W. J. Parker & Co. have just received an order for a complete steam power plant of 100 h. p., including engine, boilers and all construction work from the Elkton, Md., Electric Light and Power Co.; also a 300 h. p. Ball automatic cut-off engine from the Suburban Electric Light and Power Co., of Scranton, Pa.

NEW YORK NOTES.

The Butler Hard Rubber Company, of 33 Mercer street, this city, solicits correspondence from any one interested in storage and primary battery cells. The hard rubber cells they make are manufactured under the valuable patents granted to William Kiel, and owing to the exceeding durability and imperviousness to acids, have become recognized, it is claimed, as the best cell produced. Their construction prevents leakage and they are most satisfactory and economical. All sizes and patterns are made to order at short notice.

Truex & Vail, of the Electrical Exchange Building, 136 Liberty street, have secured the exclusive agency for the "Brilliant" high grade incandescent lamp, manufactured by the Electric Manufacturing Co., of Oconto, Wis. Although this lamp is not yet well known on the Eastern market it has gained much favor out West, and now, by the firm of Truex & Vail, will be introduced in their territory, which comprises all the New England States, New York State and Northern New Jersey.

Mr. T. A. Pamperin, the general manager of the Electric Manufacturing Company, of Oconto, Wis., makers of incandescent lamps for all systems, is now in the East and was a caller last week at the offices of The Electrical Engineer. He reports business as excellent. The company is now making lamps in all voltages from 50 to 118, and railway lamps with filament hook. Prices are maintained, as well as the quality of the product.

The Joseph Dixon Crucible Co., of Jersey City, has issued a useful little pamphlet explaining simply and clearly the value and some of the uses of pure flake graphite as a lubricant, and explaining why ordinary graphite won't do. The pamphlet should prove very interesting to mechanical and electrical engineers.

Mr. Alfred C. Boughton, a valued member of the business staff of The Electrical Engineer, was married in Brooklyn, on September 21, to Miss Ellen De Mott of that city. The happy pair are spending their honeymoon in Connecticut.

NEW ENGLAND NOTES.

Washburn and Moen Manufacturing Company, of Worcester, Mass., gave an interesting test this week of their new Salamander wire in the laboratory of the Massachusetts Electrical Engineering Company in Boston. The test was a comparative one, four different kinds of high grade rubber-insulated wires of standard manufacture being mounted on the same board, and the ends of same all joined up in series. The wires all looked equally good before the test, but afterwards there was a marked difference. The size of the wire was 14 B. & S., and 140 amperes were passed through until the copper was gradually heated to a white heat. It was observed that with the other insulated wire some took fire or burst open, or were almost consumed. The "Salamander" wire, on the contrary, remained intact, and after cooling off looked almost as good as new, as far as the insulation was concerned. The test was made to show conclusively that rubber-covered waterproof wire can be made fireproof, although up to the present no such wire has been put on the market. The copper in the "Salamander" wire is covered in the usual way with rubber insulation, which in turn is covered with a fireproof substance, which looks almost like rubber, and then braided over all and slaked with a fireproof compound. The tests proved all that Washburn & Moen have claimed for the wire, and there is no doubt but that they have filled an actual want, and that the wire will meet with an unqualified success.

Mr. J. M. Orford, who has been well known for the past eight years as the successful general manager of the Bridgeport Electric Light Company, of Bridgeport, Conn., has left that city and has accepted a position as assistant general manager of the Boston Electric Light Company, of Boston, under Mr. Fred. Gilbert, who is president and general manager. Mr. Orford has been connected with the electrical business since his early youth, and his successful career in Bridgeport has eminently fitted him for the position he now occupies, and Mr. Gilbert can well be congratulated upon securing the services of so able an electrical engineer and capable business man.

The Elektron Manufacturing Company, of Springfield, Mass., are paying special attention at present to electric elevator business in connection with several well-known elevator manufacturers. They have installed in various cities within the last few months as many as fifty of these elevators, all of which are working with satisfaction. The hoisting apparatus is driven by direct gear, the movement of the car being controlled by the movement of the motor. The Elektron Company claims that the arrangement is perfectly satisfactory and economical up to speeds of 250 feet a minute, and it will guarantee to install elevators to run at half the cost of water elevators.

The Germania Electric Company, of Boston, are introducing a line of fancy striped colored and variegated lamps, made from the finest imported French glass, and blown by Bohemian glass blowers at their factory in Marlborough. These lamps are not only in the ordinary bulbs, but are made in fancy designs representing candles, or candle flames and other attractive shapes. The colored lamps are extremely pretty, of every possible shade and design, and a peculiarly effective appearance is effected on some of the lamps by the process of matting the tinted glass.

The L. P. and D. Transmitter Company, of Montpelier, Vt., continue to have a good business in furnishing power transmitters for various purposes. Their system of transmission has proved very successful, and is attracting wide attention amongst electrical engineers. Amongst their recent sales are four to Ruben & Solomon, Pittsburgh, Pa.; one to the Du Bois Traction Company, Du Bois, Pa.; one to F. R. Dravo & Company, Pittsburgh, Pa.; one to Aneca Manufacturing Company, New London, Conn.; and one to the Arlington Mills, Lawrence, Mass.

Gillis & Gleason are successors to Albert L. Russell, of 106 Sudbury street, Boston, well known as the successor to Charles Williams, Jr. Mr. Russell has sold his business complete to the above firm, consisting of Mr. Duncan Gillis, who has for years been his confidential man, and to Mr. Thomas W. Gleason, who has for years been in the electrical business in Boston. Both gentlemen are well known to the electrical trade, and start out under good auspices, and there is no doubt but that business entrusted to them will meet with prompt and careful attention.

Mr. H. W. Somerset, late of the Mather Electric Company of Manchester, Conn., has resigned his position of superintendent for the above company to accept a similar position with the Wightman Electric Manufacturing Co. of Scranton, Pa.

WESTERN NOTES.

Paranite wire is meeting with such a growing demand that it is getting to be a case of nip and tuck with the factory to keep up with their orders. The Electric Appliance Company who are handling the Western trade are enabled to keep up with their orders with only the greatest difficulty. They state that every large shipment they receive is disposed of almost before it can be unpacked.

Mr. Wm. Taylor, Mr. Wells Goodhue and Mr. H. B. Ames who have been for many years connected with the Electrical Supply Company, have commenced business for themselves and incorporated a company under the name of Taylor, Goodhue & Ames, and will manufacture and deal in electrical material of all kinds for electric lighting, railway and power work. It is their intention to carry a large assorted stock of everything in this line so as to make prompt shipments from Chicago. For this purpose they have leased a warehouse, and for the convenience of their friends and patrons have opened a handsome suite of offices at No. 827 Monadnock Building, Chicago. Mr. Taylor is president of the new company, Mr. Goodhue, vice-president; and Mr. Ames, secretary and treasurer.

Mr. Frank E. Shepard, of the firm of Shepard & Searing, mechanical and electrical engineers, Denver, Col., is spending a month among the New England States on a trip of business and pleasure combined. Mr. Shepard was for two years U. S. Marine Boiler Inspector for New England, and the many friends he made in the service will be more than glad to welcome him back to the "old stamping ground." He will visit many of the new electric lighting and power plants, and make a special study of the L. P. & D. system of transmission at the Concord Gas Company's plant, Concord, N. H. Mr. Shepard will be in Boston on the 5th of October, in order to be present at his brother's wedding.

The Electric Appliance Company are exhibiting a sample of the Schuttler ratchet track drill in their store at 242 Madison street Chicago. The rapidity and ease with which it puts a hole through a section of rail is really marvelous, and it will undoubtedly be only a matter of time before it will be generally used for street railway work. The Electric Appliance Company have in preparation a modified form of the drill which will be known as the "shop drill." This is designed for general shop work as well as a track drill, and will be a very desirable tool around every electric light station and street railway plant.

Mrs. George Brown, wife of the general manager of the Pullman Palace Car Company, and mother of Charles E. Brown of the Central Electric Company, died at Gloucester, Mass., on the 12th inst., as the result of injuries received four weeks ago. She was then driving with some friends, when the carriage was overturned and her spine hurt. Mr. Brown has the sympathy of his many friends in his bereavement.

Mr. George Cutter, the electrical specialist of the West, is just moving into larger quarters in Chicago, and his address hereafter will be 329 the Rookery, that city. He will continue to handle a number of valuable specialties, and will also be heard to make some casual remarks about "Simplex."

Wm. Hood & Co., manager of the Chicago office of the Electric Manufacturing Company, makers of the "Brilliant" incandescent lamps, reports the receipt of numerous large orders, and states that the lamps are giving perfect satisfaction, as all those who have used them are ordering more.

Mr. H. E. Seemuller, formerly connected with the advertising department of the Yale & Towne Manufacturing Company, recently accepted a position with Henry R. Worthington at their Chicago branch.

Clark & Marshall, No. 4'3 The Rookery, have secured the Western agency for the Boston incandescent lamp, manufactured by the Boston Incandescent Lamp Co., of Boston Mass.

The Central Electric Company report large sales of triple and double braid weatherproof wire, besides a steady demand for Okonite wire, cord and Manson tape.

CANADIAN NOTES.

The Brantford Electric and Power Company, Limited, will apply for incorporation, with a capital of $150,000. Its object is to acquire and develop the water-power of the Grand River, at Brantford, Ont., of which, it is estimated, a minimum of 650 h. p. will be available for conversion into electricity and distribution for light and power. This company will also acquire and operate the plant and property of the Brantford Electric Lighting Company, whose present arc and incandescent lighting systems will be extended.

Mr. T. Ahearn, of Ottawa, has disposed of the United States patents on his electrical car heaters to the Railway Equipment Company, of Chicago. These heaters were used on the cars of the Ottawa Electric Street Railway during the past winter with the greatest success. The cars were comfortably warmed on the coldest days when the temperature was below zero, which the other heaters used had failed to do.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

THE
Electrical Engineer.

VOL. XIV. OCTOBER 5, 1892. No. 231.

THE GENESIS OF THE MODERN DYNAMO: ANTONIO PACINOTTI.—III.

BY

Franklin Leonard Pope

Pacinotti at the Age of 23.

Having completed his service in the army, Pacinotti returned to Pisa, and for a time was so fully occupied in preparing for his approaching University examinations, as to render necessary the intermission, for the time, of the course of experimentation upon which he had entered with such promising results. In the spring of 1860, he resumed his investigations and it was at this time that with the assistance of Joseph Poggiali, the mechanician of the Physico-Technological Cabinet of the University of Pisa, he constructed the now well-known little machine, which in later years, was destined to confer such high distinction upon its fortunate designer. After such progress had been made in the construction of this apparatus as to permit of the making of tests, the following memorandum was entered in the notebook of projects of 1858:

> April, 1860. The electromagnetic machine of which the first notions are found hereinabove recorded, has been constructed by me as a small model * * * * * * This machine has a single stationary electromagnet. It acts well as a magneto-electric machine, since it gives a continuous current always in one direction and very intense [strong].

Upon a loose sheet of paper, Dr. Pacinotti has fortunately preserved a number of memoranda, noted down at the time, of the results of these tests. Among these results are determinations of the mechanical work obtained by means of the machine, from one, two, three and four small Bunsen cells under various conditions, as for example, (1) when the same current traversed both the armature and the field magnet; (2) when the current from three cells traversed the armature alone; (3) when the current from three cells traversed the armature, and that from two additional cells the field magnets. These measurements are dated June 22, 1860. The next day, June 23, the order of the experiments was reversed, and on the same sheet as the preceding are found recorded a number of measurements of the value of the continuous direct currents obtained from the machine itself, by rotating the armature at different speeds, as well as by varying the angular position of the contact springs upon the commutator.

In September of the same year, Pacinotti prepared a thesis, which although never as yet published, was in some respects more complete in detail than the article published five years later in *Il Nuovo Cimento*. In this paper, the author sought to enumerate the advantages which he believed his apparatus to possess over those previously known, and expressed a desire that an opportunity might be found for it to undergo competitive tests, in comparison with other known machines.

With a view of making such tests, Pacinotti obtained, after his return to Pisa at the beginning of the scholastic year of 1860-61, a small model of Froment's electromagnetic motor, a well-known piece of laboratory apparatus, and at once undertook to make careful determinations, not only of the mechanical work actually produced, taking friction into account, but of the differences in the value of the current when the machine was at rest and when it was in motion, and of the internal resistance between the terminals of the machine under these different conditions. The notes made at the time of some of these quantitative results have been preserved. Subsequently, some of these observations were reduced according to the theory of Jacobi, as given in Note D of De la Rive's *Traité d'Electricité*, showing for the machine of Pacinotti a higher economic efficiency than for that of Froment.

An interesting unpublished manuscript of this date discusses at a considerable length the general theory of electromagnetic motors, in which the author has attempted to more completely develop the well-known theory of M. Jacobi. The note referred to in the treatise of M. De la Rive contains also a communication from M. Soret, in which it is pointed out that the currents of induction developed in the stationary helices at the instant of closing of the circuit constitute the chief obstacle to the development of an augmented current in proportion to the increase in the power applied to effect the rotation of the machine when used as a generator. This observation of M. Soret led Pacinotti, by a logical course of reasoning, to anticipate results of value from the system of connections which he had originated, in which the construction of the commutator was such as to occasion no interruption of the current, and which tended therefore to avoid most of the inconveniences likely to arise from induced currents.

Just as Pacinotti had reached this most interesting stage in the progress of his investigations, he received the unexpected honor of a nomination for the Assistant Professorship of Astronomy in the Royal Museum of Florence. The offer was too flattering a one to a young man just entering upon a promising career, not to be accepted, and although for many years the youthful philosopher did not forbear to cherish the idea of extending his investigations, by the construction of a machine of much larger dimensions, yet he found his time was so fully taken up by the duties of his new position that he was unable to do so. At length therefore he wisely determined to place on record an account of his work so far as it had gone, which he did by preparing and publishing the article heretofore reproduced, in *Il Nuovo Cimento.*

A BIOGRAPHICAL SKETCH OF THE KHOTINSKY ACCUMULATOR.—IV.

BY

Capt. A. de Khotinsky

For my living I had to seek other employment, and I found it with a London firm in joining small pieces of amber and giving them a certain form, which process I devised in the laboratory of my friend, Mr. L. Warnerke. After this work was completed, Mr. Warnerke placed at my disposal, in the most unselfish and friendly way, his laboratory and workshops. There I occupied myself in making filaments for high potential lamps.

In June, 1883, I became acquainted with Mr. La Grange, of Rotterdam, who heartily interested himself in my accumulators and opened bright prospects to find capital in Holland for carrying on the business there. At his request, I built in Charlton a battery, and went with it, in August, 1883, to Rotterdam. After several public experiments with this battery, and on account of the recommendations of Mr. Preece in London, a stock company, called the Electriciteits Maatschappy, System de Khotinsky, of Rotterdam, was formed. After returning from Paris to London I had—following Mr. Preece's advice—taken out a patent on the accumulator.

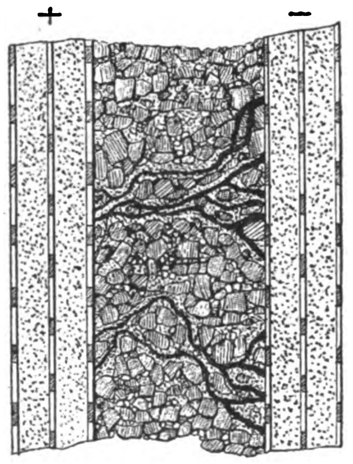


FIG. 13.

The battery with which I experimented in Holland was built according to the same patent, with this improvement, that the space between the positive and negative plates was filled with granulated pumice stone, which prevented the swelling up of the positive plate.

The tendency of the positive plates to swell up and, by contact with the negative, to cause a short-circuit, I had already noticed in my experiments in England. To gather more experience by experiments on a larger scale, the company ordered me to light, by accumulators, two blocks of houses, chiefly offices of merchants. It required about 250 glow lamps of 16 c. p. each. I built, therefore, accumulators exactly like my experimental battery, only larger, and instead of hard rubber boxes I used wooden ones. The batteries were set up in two small boats for the purpose of charging the accumulators during the day from the factory, situated on an island in the river Maas, so that they would be ready for delivery in the evening at the block stations in the harbor. For this reason it was necessary that the batteries should be arranged as transportable accumulators. The experiments were continued during eight months and gave me sufficient opportunity to detect the deficiencies which yet adhered to their construction.

The first fault I observed was that when the battery had been for some time on open circuit internal discharge occurred in some cells. I examined, therefore, the plates of these cells and found them in perfectly good condition. I fitted them out anew, set them in action, and then the internal discharge apparently discontinued and the battery worked normally. Two weeks later the existence of internal discharge again appeared in other cells. I observed thereby that during the charging of the cells in which the inner discharge occurred the boxes became hot, not over the whole surface, but only in certain parts, and in most cases at the lower part of the box on the edge side of the electrodes. This circumstance convinced me that in these places an imperfect inner short-circuit existed. In order to find the cause of the short-circuit I found it necessary to break the boxes without touching the plates, for if I were to take out the plates I must first remove the pumice stone and thus destroy the very sensitive places of the short-circuit, which I wished to see.

When the box of the self-discharged cell was opened in this way I found on the top of the warm spot, between the granulated pumice stone, ramifications of fine powder the color of which was yellowish brown at the positive plate and passing to metallic gray at the negative, having the appearance shown in Fig. 13. On examining other cells immediately after the charging I found the same ramifications, but their color was entirely metallic gray. In both cases the root of the ramifications started at the negative plates from the outer perforation of the enveloping sheath. These ramifications always formed themselves in places where the finest powder of the pumice stone was situated.

In searching for the inner short-circuit, I observed that the positive plates commenced to become ruined at the lowest parts while the upper parts were perfectly sound and good. I opened the electrode and found that the lower part of the sheathing had completely oxidized, while the inner plate, even at the lower end, showed only one-tenth mm. of oxidization. The whole quantity of spongy lead was changed into peroxide and appeared in the form of a free powder which had fallen from the carrier by its own weight and become deposited at the lowest end of the plate in compact masses.

I noticed that the destruction of the positive electrode began at the lower part on account of the higher specific gravity of the acid at that point, for on first charging and discharging a cell I noticed that the acid is heavier at the lowest point. This is caused by the fact that in discharging the active mass the electrode combines with pure sulphuric acid which becomes free again at the next charging and sinks to the bottom along the outside of the electrode.

In experimenting with one cell filled with well-mixed 10 per cent. solution of acid, after a few successive charges and discharges, I found that the specific gravity of the acid in a charged cell changed so that in the upper part 2½ per cent. and at the bottom 30 per cent. of acid was found in solution. To obtain successful results from these experiments great care must be taken not to overcharge, because the rising of the developing gas will artificially mix the acid.

From this confirmed fact it follows that the lower part of a plate must be sooner destroyed by extra work imposed on it by the stronger acid, and by the same agency in the lower part the internal resistance is reduced while in the upper part of the plate, by reason of the lighter acid, the opposite occurs and the internal resistance is therefore increased.

MR. C. G. YOUNG, late superintendent of the Mt. Morris Electric Light Co. of this city, has resigned his position and has associated himself with the firm of J. G. White & Co., the electric railway contractors. He will devote himself to the new field of work and is already busy on construction work in Baltimore.

THE POOL MOTOR AND DYNAMO.

AMONG the dynamo-electric machines of recent design possessing novel features is that of Mr. J. G. Pool, electrician of the Hubinger & Pool Co., of New Haven, Conn.

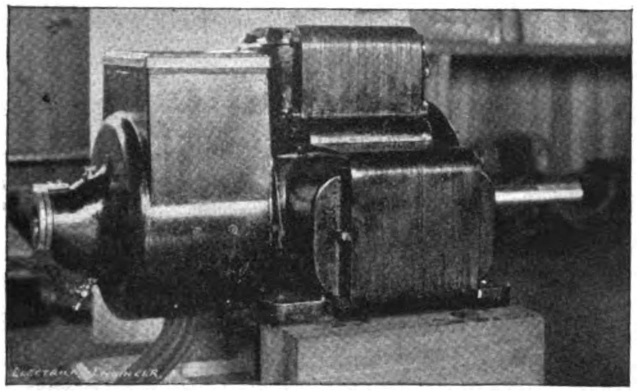

FIG. 1.—THE POOL MULTIPOLAR MOTOR.

The machine was designed especially for the purpose of operating electric yachts, but is also equally applicable to mining work, portable hoisting and pumping machinery, fire engines, and for all purposes where a motor may be required for service in wet or damp places or where exposed to the weather. It goes without saying, however, that it may also be used in all places where a motor or dynamo may be required.

The accompanying engraving, Fig. 1, shows the machine complete, and Fig. 2 shows it turned 90 degrees from its proper vertical position, exhibiting the commutator and brushes, the cover of the box enclosing the latter being removed. In practice this box is closed by a glass plate so as to show at all times the condition of the commutator and brushes. Fig. 3 shows the end of the armature case removed and the end of the armature as it appears in place in the field, illustrating the proportional size of armature as compared with the other dimensions of the machine, as well as the method of mounting the armature on the shaft.

The motor has been designed with special regard to efficiency and durability, and the protection of all wires and working parts from injury, either by moisture or otherwise. The field magnets are iron clad, the exciting coils being entirely surrounded by iron, the magnetic circuit being exceedingly short and without break. The field magnets are laminated, being formed of alternate layers of the best charcoal iron and paper similar to the construction used in armatures. Foucault currents are thereby entirely avoided and the machine runs cool even when overloaded.

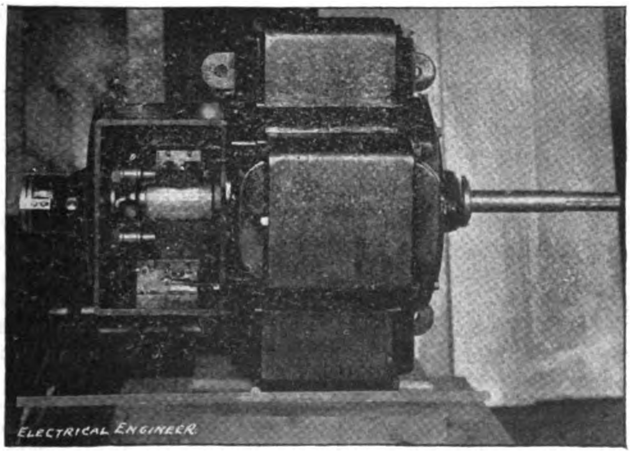

FIG. 2.—THE POOL MULTIPOLAR MOTOR.

The engraving Fig. 4 shows the shape of the sheet iron stamping of which the field magnets are constructed, one die answering for all of the eight positions in which it is placed and producing a magnet which when put together is as stiff and rigid as a solid piece. An inspection of Fig. 5 will readily show how this is accomplished. A layer of pieces such as is shown in Fig. 4 are first placed together on a flat surface and held in position by rods or bolts passed through the holes, the junctions of this layer being represented by the dotted lines B, Fig. 5; the next layer of plates is then reversed, the junctions appearing at the solid lines E. This alternation of layers is continued until the proper thickness for the field is attained, the projections D interlocking throughout, thus producing a solid, laminated field without break in the magnetic circuit and at a minimum of cost.

The field coils are wound on spools and slipped in place and secured there by clips not shown. The magnetic circuit being very short the amount of wire required to excite the fields is very small, being in this machine only 35 pounds. The magnetic circuit is shown in dotted lines through one portion of the field, which constitutes eight poles, alternately north and south.

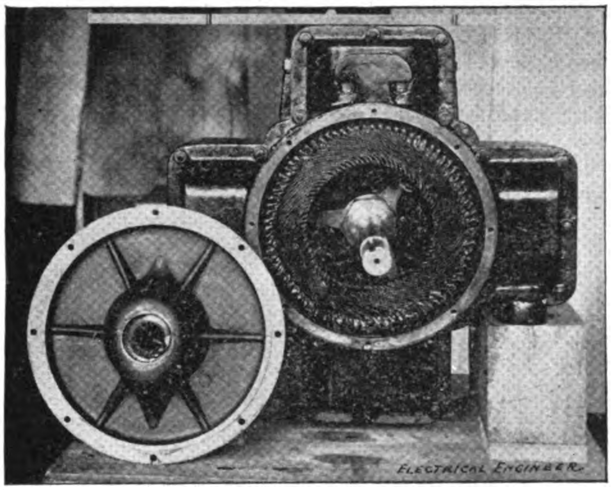

FIG. 3.—THE POOL MULTIPOLAR MOTOR.

The winding of the armature is such that the actions which take place are precisely the same as those which occur in the best style of cylinder armature when placed in a bi-polar field, each wire being carried in alternate directions under each pole of the field before being carried to the next bar of the commutator. Each wire is of exactly the same length as every other and occupies an exactly similar position in the field.

The various wires forming the winding are connected in series without any cross-connections of either wire or commutator and only two brushes are required, set at a distance apart on the commutator equal to the angle formed by two adjacent neutral points of the field. This method of winding obviates all of the objections which have been raised against the multipolar type of machine, while all of the advantages of this method of construction are retained. In the armature of the machine shown each pole of the field generates only a fraction of the electromotive force, such fraction being represented by the number of poles in the field, the electromotive forces generated being joined in series by the peculiar method adopted in winding without cross-connections. Each portion of each wire is equally influenced by each of the poles of the field at each instant, producing a complete electrical balance independent of the strength of any individual pole of the field. The armature is of special design, the wire being wound in grooves and entirely imbedded beneath the surface, thereby reducing the gap between the armature and field poles to the smallest possible amount. The resistance of the armature is $\frac{12}{100}$ ohm.

The machine runs with absolutely no spark from full load to no load and vice versa; the direction of motion may also be reversed and the machine operated throughout its full range and without moving the brushes and without spark. The brushes may be moved through an angle which is almost equal to two adjacent neutral points of the field without causing a spark.

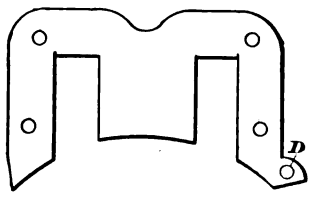

FIG. 4.—FIELD MAGNET STAMPING.

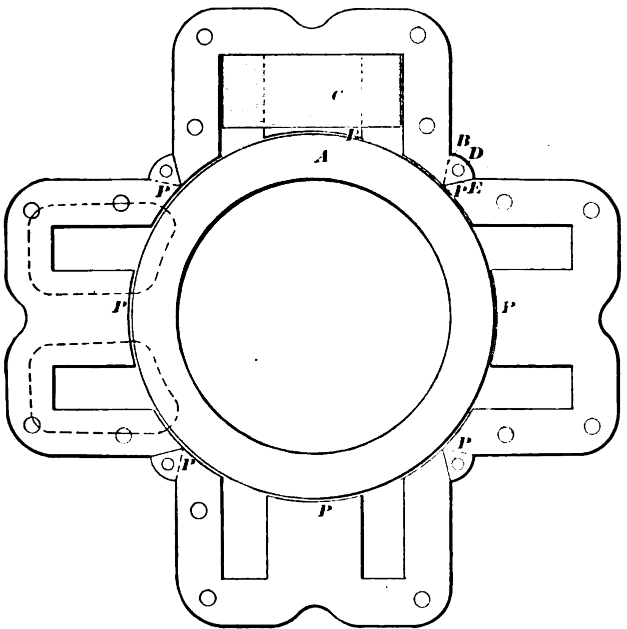
The machine is entirely encased in iron and may, if required, be placed and operated in the open air without protection in any weather or climate, thus affording a machine suitable for many purposes for which the electric motor has not heretofore been adapted.

The machine is self-oiling throughout and requires no attention. The centre of gravity is very low and it is peculiarly adapted to the operation of electric yachts for which it was originally designed, its shape allowing it to be placed low (as it nearly conforms to the shape of the hull) and to be coupled to the propeller direct. The machine is designed for an electromotive force of 120 volts.



Elec. Engineer

FIG. 5.—FIELD MAGNET OF POOL MOTOR.

A NEW MAGNETIC ROCK.

A GREEN rock, strongly resembling serpentine in appearance, has recently been discovered in large quantities at Borzanasca, in Liguria. The most curious feature about it is that it possesses distinct polar magnetism. The rock has been analyzed, and found to consist of silica, 39.84; alumina, 3.08; iron oxides, 7.07; magnesia, 36.63; lime, 1.14; water, 12.86. The microscope reveals the presence of bastite and small crystals of diopside, diallage and chrysotile, but the magnetic properties are difficult to account for.

TWISTING MAGNETISM?

BY

Chas. Steinmetz.

IN a recent issue of THE ELECTRICAL ENGINEER, I read an account of a unipolar machine, under the above heading, and regarding which I should like to make some remarks.

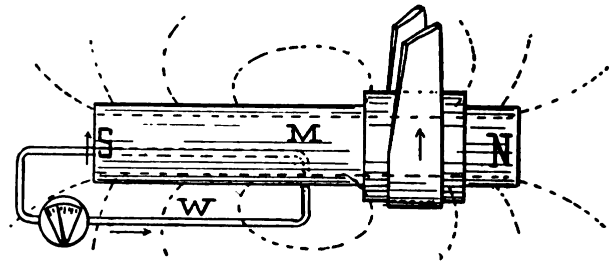


FIG. 1.

While the machine shown in Fig. 1[1] will give a small E. M. F., the machine in Fig. 3 *cannot* give any trace of E. M. F. not because the magnetism does not twist, but because the magnetic field of a magnet does *not revolve* when the magnet is revolved, but remains *stationary*, uninfluenced by any revolution of the magnet or the exciting helix, which, as is known, is a magnet even without iron. Consequently, in Fig. 1, in the outside conductor W, no E. M. F. is induced by the revolving magnet; but the seat of the observed E. M. F. is the inside conductor, the magnet M S itself, which in each revolution intersects all the lines of magnetic force once.

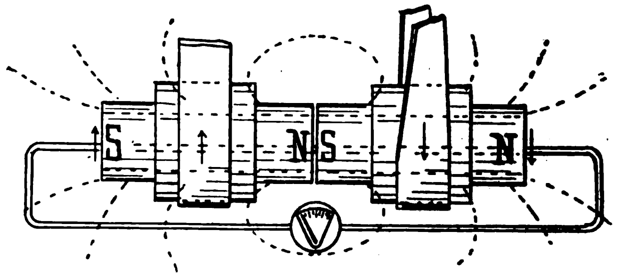

FIG. 3.

Now consider Fig. 3. The outside conductor is dead again, being stationary in a stationary magnetic field. But the inside conductor in either of the two magnets intersects every line of magnetic force twice in opposite directions, and consequently is the seat of two equal and opposite E. M. F.'s, which completely neutralize each other, so that the result is nil, as observed.

We would, however, get a current from the arrangement in Fig. 3, if the two magnets at their adjoining faces were connected not inside, but on the outside, by a conducting sleeve bearing upon both magnets; because in this case the lines of magnetic force passing through the gap between the magnets would be intersected twice per revolution by the conductors forming the revolving connections from the outside ends of the magnets to the connecting sleeve.

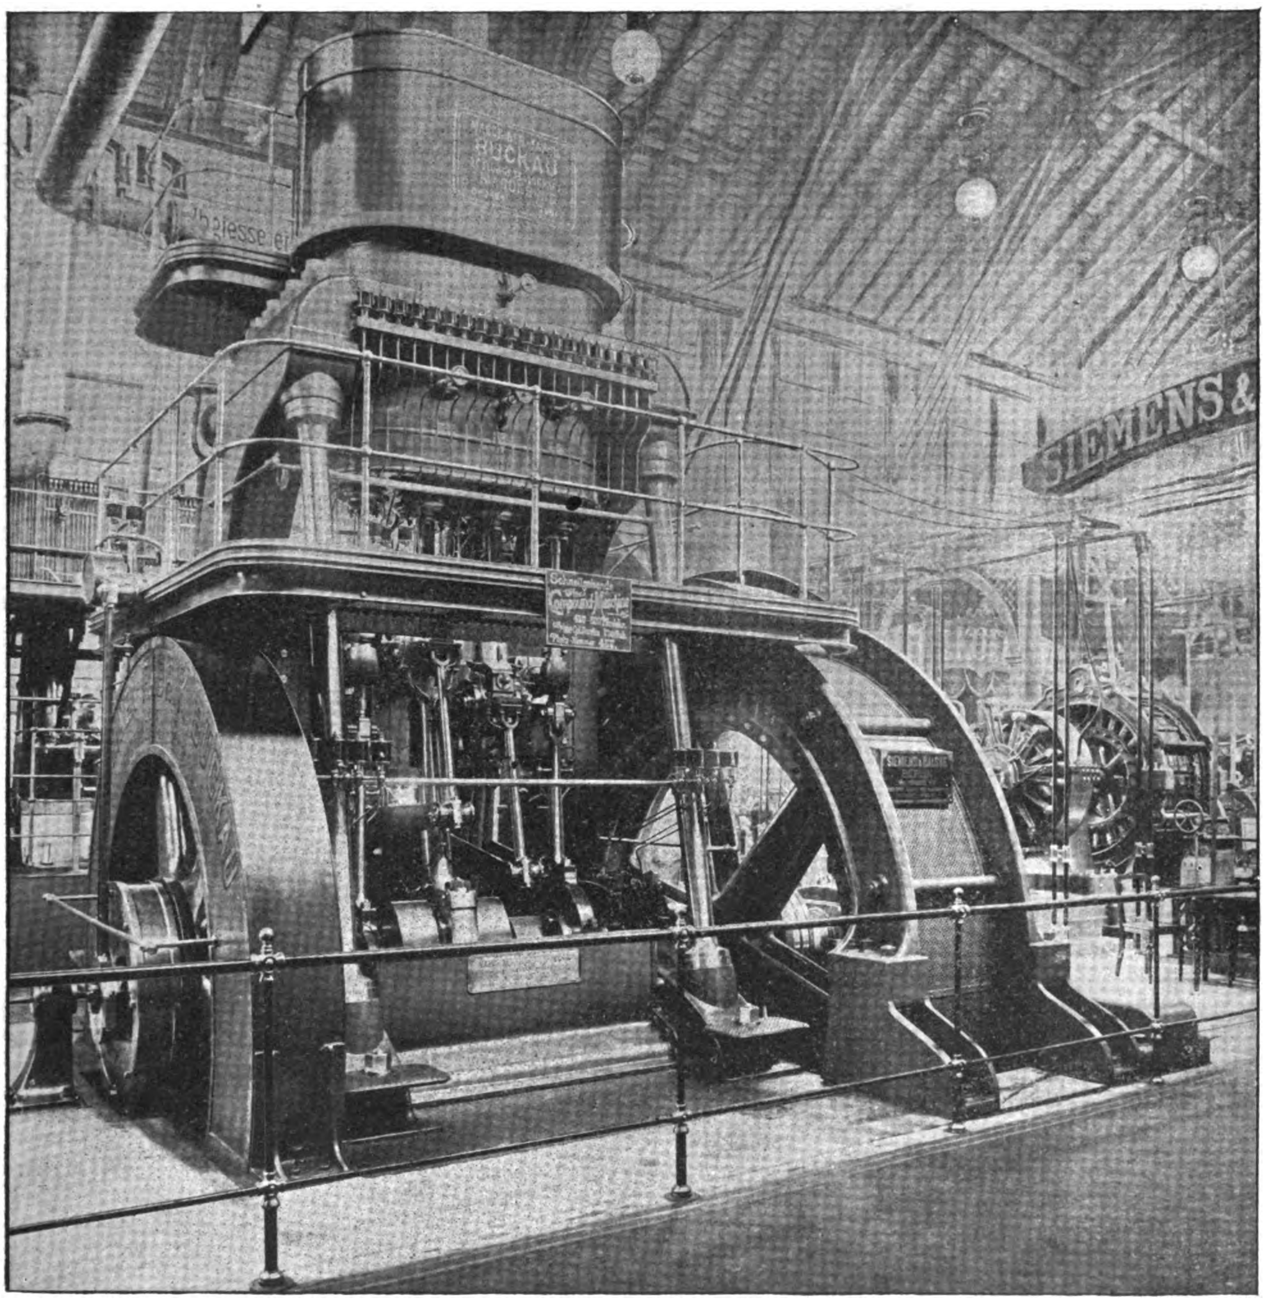
---

[1] Figs. 1 and 3 are reproduced from our issue of Sept. 14.—EDS. ELECTRICAL ENGINEER.

SIEMENS & HALSKE DIRECT-DRIVEN CONTINUOUS CURRENT AND ALTERNATING GENERATORS.

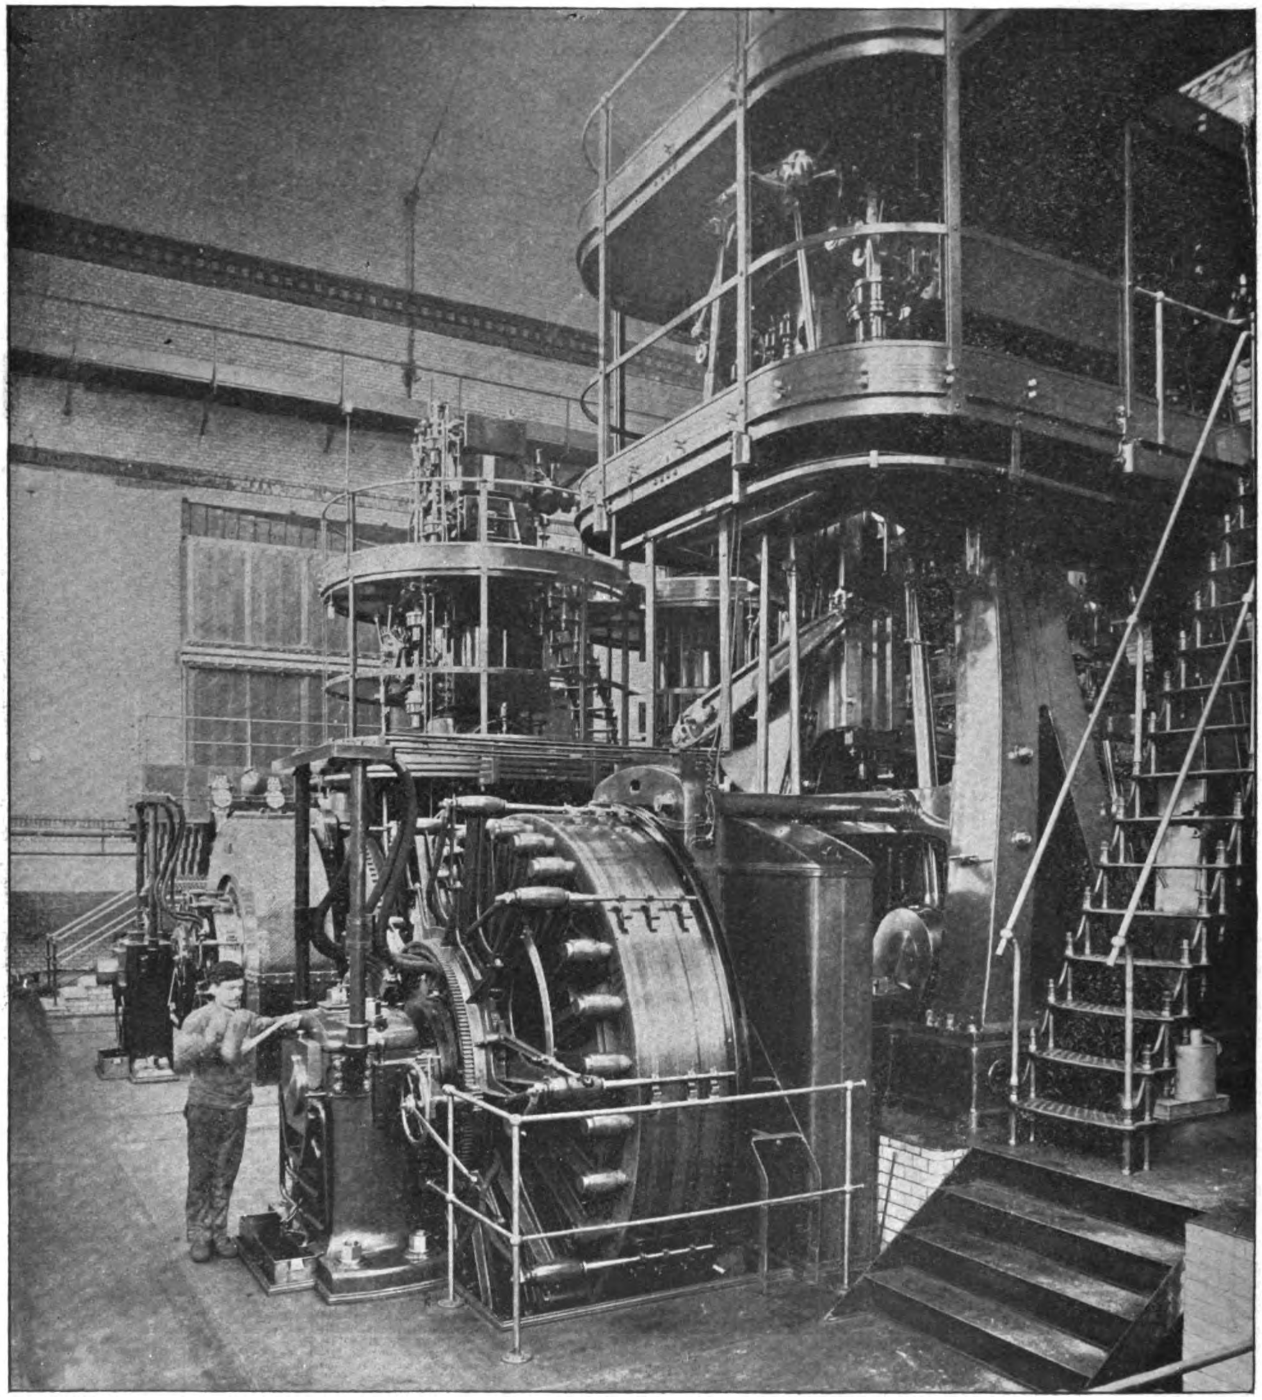
SIEMENS & HALSKE, believing that a large dynamo, coupled directly to the steam engine shaft, running at comparatively low rates of speed, thereby saving the expense of belting, with its corresponding loss of power through friction, slipping, etc., was bound to be the machine of the future, turned their attention to the designing and construction of such machines, and have gone from 500 h. p. to 1,000 h. p., thence to 1,500 h. p. and now 2,000 h. p., a size about three times as large as built so far in this country.

The mechanical, electrical and financial results achieved by the Siemens & Halske large dynamos fully warrant the belief of those who advocate such large machines. The accompanying illustration shows one of the 1,000 h. p. alternating machines coupled direct to a 1,000 h. p. Collman engine. This machine develops 700,000 watts, 2,000 volts and 350 amperes. This machine has 60 poles. The armature is stationary. The field magnet ring consists of 60 bobbins, rotating inside the armature, which has the same number of coils. The outside diameter of the rotating field magnets, is 12.2 feet; the armature, 15.1; number of revolutions, 100 per minute, so that it has 6,000 alternations per minute. The field magnets are excited by a direct current, which is brought from an exciter machine. Every coil is insulated with hard rubber from all metallic connections, and the stationary armature, such as is used in this type of machine, enables the makers to provide much better insulation than when the armature itself revolves.



THE SIEMENS AND HALSKE DIRECT DRIVEN ALTERNATING GENERATOR OF 1,000 H. P.

The other illustration shows the direct current dynamo. It is of the inside pole ring type, which class has from four to twelve poles. They are placed in the form of a star inside the rotating armature. The brushes, which are always of the same number as the field magnets, take off the current from the outside of the armature winding. The armature itself consists of an iron ring wound with copper segments. The special machine illustrated has ten poles and is designed for an output of 746,000 watts. This machine can be built without special commutator for from 100 to 700 volts, and can be used for lighting and power. The drop of potential in the armature is only 2 per cent. with maximum load. For exciting the field magnets, only ½ per cent. is required. Therefore, the electrical efficiency of this machine is about 96½ per cent. It is shunt-wound and has a peripheral speed of 50 feet per second.



THE SIEMENS & HALSKE DIRECT DRIVEN CONTINUOUS CURRENT GENERATOR, INSIDE POLE RING TYPE.

The works of the Siemens & Halske Electric Company, of America, are located in Chicago. They receive all drawings from Berlin, and will duplicate the construction that has resulted from the vast experience gained by Siemens & Halske during the half century of their existence.

THE AHEARN electric cooking apparatus, which was recently used at the Windsor Hotel, Ottawa, Canada, in cooking a whole dinner, is now on exhibition at the Central Canada Fair, Ottawa, where R. E. Jamieson, baker and confectioner, employs it in baking cake, bread, etc. We have just received from the fair a tea cake beautifully cooked in the Ahearn electric oven. Truly electricity "takes the cake" now-a-days.

THE LEONARD THREE-WIRE PLANT AT CHARLESTOWN, W. VA.

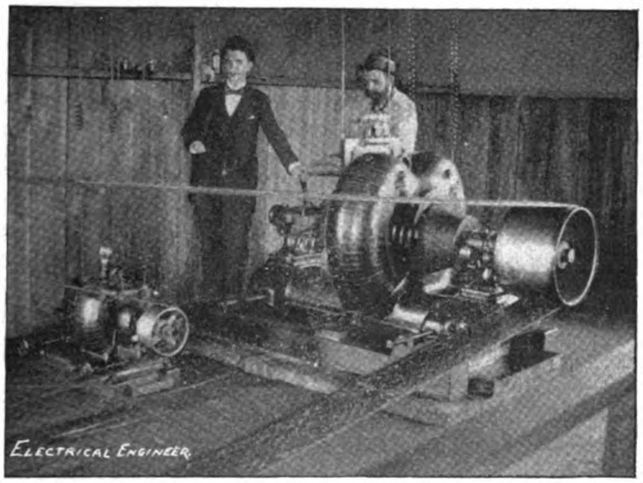
The Leonard three-wire system is identical in every way with the familiar Edison three-wire system, from the switchboard to the lamps inclusive. The first cost, efficiency and method of handling the system of conductors are exactly the same in every respect in the two systems. The difference between the two lies in the source of electric energy. In the Edison system there is a divided source of electrical energy, with the neutral wire connected at the point of division. That is, in the Edison system two dynamos, identical in size and voltage, are connected in series with each other and the neutral wire of the three-wire system is connected between them.

In ordinary practice, for incandescent lighting each dynamo produces about 125 volts. In the Leonard three-wire system (see diagram) there is one dynamo of 250 volts, which is connected to the outside wires of the three-wire system, and this dynamo is the source of electric energy and the neutral wire is not connected to it at all. But a very small compensating dynamo of 125 volts, and, perhaps, 20 amperes, is connected between the neutral and one of the outside wires and this compensating dynamo is connected by a belt to the same motive power that drives the large dynamo.

This compensating dynamo operates sometimes as a generator and at other times as a motor, depending upon the preponderance of load on one side or other of the system. The field of this small machine is wound for 250 volts and is excited by a derived circuit from the large dynamo.

The large dynamo is shunt-wound and self-exciting, hence an adjustment of its field rheostat not only increases the E. M. F. of the large dynamo, but also the E. M. F. of the small compensating dynamo in the same proportion, so that the E. M. F. of both sides of the system is increased or decreased at will by the movement of the one rheostat in the field of the large dynamo, thus considerably simplifying the regulation of E. M. F. upon the system.

The number of dynamos being reduced by one-half, the care of bearings, brushes, etc., is greatly reduced, as also the chances of burn-outs and other accidents.



The Leonard Three-Wire Plant at Charlestown, W. Va.

The first central station ever put in operation on the Leonard three-wire system was at Charlestown, W. Va., a town of about 3,000 inhabitants.

A well-known electrical company had taken a contract to establish a continuous current plant. The plant was to be one of 750 lights. The distances were considerable, the station being located entirely outside of the town at a distance of three-quarters of a mile from the nearest lighting. The cost of copper by the two-wire system would have been about $8,000. By the use of the Leonard three-wire system the cost of copper was reduced to $2,500, a net saving of $5,500, or over $7 per lamp. In this case, by the Leonard three-wire system the cost of copper was a little over $3 per lamp. In the average case, when the distance to the lighting is less, the cost of copper will range from $1 to $2.50 per 16 c. p. lamp.

In the picture given herewith, showing the plant at Charlestown, W. Va., operated by the City Electric Light Company, the comparative size of the two dynamos is clearly shown, the larger one being 40 K. W. and the small one 2½ K. W. In the case of larger plants, the difference between the capacity of the main dynamos and the compensating dynamos becomes still more marked.

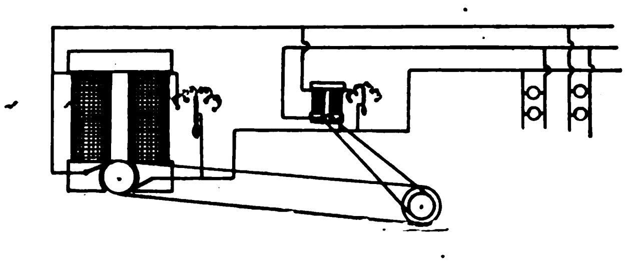


Diagram of Leonard Three-Wire System.

The average cost of a central station of 1,000 lights (16 c. p., 50 watts, 110 volts) on the Leonard three-wire system, we are informed, would be about as follows:

Dynamos, instruments and switchboard	$2,000
Copper for three-wire system	2,500
Pole line and construction for same	1,000
Services and wiring for 1,000 16 c. p. lamps, with lamps and sockets	2,500
100 h. p. steam plant	4,500
Lot and building	2,500
	$15,000

The revenue from such a plant, properly operated, in a town of about 4,000 inhabitants, would be about $750 to $800 per month, and the operating expenses about $450 to $550 per month, varying with the local conditions.

A CONSOLIDATION OF BRASS MANUFACTURERS.

Thomas B. Kent, vice-president of the Holmes, Booth & Hayden Manufacturing Company, in speaking of the report of a proposed brass trust, said last week that no "trust" would be formed. "There have been several meetings of the brass manufacturers who have plants in the Connecticut valley, with a view towards consolidation, but there is neither talk nor thought of a trust. No plan has yet been fixed upon, but I hope that by the beginning of next year the consolidation will be effected. It would be an excellent thing for all concerned, and the expenses of manufacture would be lessened greatly. Where we now have five New York offices, under consolidation one would suffice. We now spend about $50,000 a year each in advertising. That amount would be sufficient for us all if we consolidated, and the reduction in all other branches, save that of actual manufacture, would be the same. The gross output of the companies would not be reduced, and instead we would try to secure more foreign trade. There would be no competition, but the price to consumers would be lower if any change were made. There will be no stock for sale; it will be allotted to each manufacturer in a direct ratio to the actual value of the plant. Nothing is settled yet, however, and our plans may come to nothing after all."

Among the companies interested in the proposed consolidation are the Scovill Manufacturing Company of Waterbury, the Holmes, Booth & Hayden Company of Waterbury, Plume & Atwood of Waterbury, Benedict & Burnham of Waterbury, Waterbury Brass Company, Ansonia Brass and Copper Company of Ansonia, and the Coe Brass Company of Torrington. The capitalization will probably be from $12,000,000 to $15,000,000.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 203 *Broadway, New York City.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XIV. NEW YORK, OCTOBER 5, 1892. No. 231.

Think of a city operated by science, as every city might be now, without one of the wretched animals tamed by the savage man! A city without a horse, where electricity brought every man and everything silently to the door.—William Dean Howells.

ROOM FOR ALL IN ELECTRIC TRACTION.

PROBABLY at no previous time in the history of electric railroading in this country has the question of the methods of traction occupied so prominent a place in the thoughts not only of electrical engineers, but of the public as well, as at the present moment. The trolley is well established, and appears to be destined to a long career of usefulness; still it would not be risking too much to hazard the opinion that both the storage battery and underground conduit systems will find more or less application in the not distant future. The recent communication by "Gautherot," which appeared in our columns, pointed out very forcibly the reasons why storage battery traction has not been, thus far, successfully carried out in this country. The word "successful" here used refers particularly to the commercial aspect, rather than to the electrical, for that storage cars can be operated needs no further demonstration at this late day. On this subject Mr. G. Herbert Condict, whose experience in this field has extended over a long period, strongly supports the position taken by "Gautherot," and he also points out another fact which is frequently lost sight of by those undertaking storage traction work, namely, the selection of roads for experimentation which are essentially unsuitable to this class of traffic. While it is true that a successful system must eventually be one capable of being placed on any line, it is surely overtaxing a young and struggling system to break it in, as it were, on roads with difficult grades, bad tracks and heavy traffic. What has just been said is also applicable, for the most part, to underground traction. The failures which have attended attempts in this direction, so far, in this country are, we believe, traceable more to financial than to any other reasons; but the success already obtained abroad, and, we may add, even in experimental instances in this country, leaves no room for doubt that we shall soon see more of this system in actual work. We believe that the history of electric traction in the future will be a repetition, in a way, of that of electric lighting.

Having thus placed ourselves on record, we may, perhaps, be permitted to congratulate the Metropolitan Traction Company of this city on obtaining permission that will enable them to run trolley cars into the city proper under the Elevated Roads and elsewhere. This is a great gain and a long step forward in rapid transit work, and we know that in the city, as in the suburbs, the trolley will be found by the public to be a most useful addition to the facilities of travel. The public is ready for it. We are told by the press that the public is intense in its opposition to it. This is wantonly and absolutely untrue. A close perusal of all the city papers for the past six months has failed to show us the slightest evidence of an antagonistic public sentiment outside their own editorial pages. But if there is such a public feeling, why does it not manifest itself up in the Annexed District, where the Union Railway Company is now running trolley cars on several lines? Last Sunday we found it impossible to get a foothold on the cars, so jammed were they with jolly and enthusiastic crowds of the plain commonsense New Yorkers, who never yet allowed themselves to be prejudiced against a good thing simply because it was new.

STORAGE BATTERY STATIONS.

IN commenting on the views expressed through these columns by a well-known engineer recently returned from a trip of inspection through Europe, the London *Electrical Review* remarks that his opinions must have been formed upon too narrow a basis and upon too hurried an examination. This is by no means the case. Our communicant is known everywhere as an able and most careful engineer. He went abroad wishing to be convinced, and came back believing that in stations with a large day load, the battery had no chance, so far as America is concerned. We gave currency to his views because to some extent they controverted our own, and because we wish to see the matter threshed out. We are still decidedly of the opinion that a great many of our small stations need battery equipments for their hours of light load, and we hope to see the plan adopted. But we cannot quite reason ourselves into the position that a light load is desirable, because it gives you a chance to use storage batteries. The best station business is that which has a good load diagram all the day through, all the year round. A summer hotel may do a very paying business for three months in the year—our experience as a guest runs that way—but after all it is not as profitable and satisfactory as a city hotel which has its rooms full from January to December. In the same way we can understand the conditions under which a station six hours out of the twenty-four is earning well, but simply exists the other eighteen by the aid of the batteries. It must be evident that a station with a heavy day load for light and power is in better shape by being able to get along without the batteries. And this is true without any reflection on batteries as a valuable adjunct in certain places.

ELECTRIC RAILWAY DEPARTMENT.

A PRACTICAL CONDUIT TROLLEY SYSTEM.

BY

RJ Hewett

In working out this system the writer has been guided mainly by the conditions and requirements of practical conduit work, an outline of which has been given.[1] Fig. 1 is a cross-section and Fig. 2, a longitudinal section showing the conduit trolley device and truck.

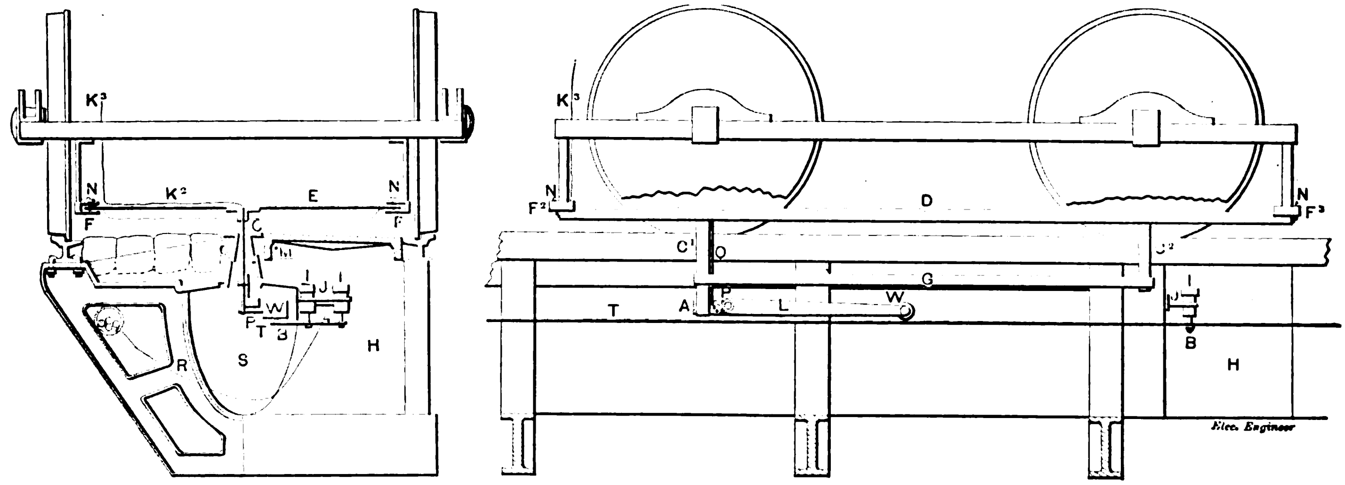
The conduit and permanent way are patterned after regular cable conduit work and constructed in a similar manner. The conduit S, Fig. 1, is 29½ inches deep by 18 inches wide. The roofof the conduit is formed of wrought iron angle plates, U U, resting on overhanging arms of the yokes. On top of the angle plates are placed the sand bed and paving blocks .

A feed-wire conduit composed of tubes of suitable material such as well-glazed terra-cotta is built into the concrete body of the conduit. In construction, the tubes are secured to the yokes, passing through an opening, as shown; the joints are properly made and concrete filled in around the tube at the same time that it is filled in to form the main conduit. Thus we are able to construct the feed-wire and main conduit all at once. Manholes are placed at suitable intervals on the feed-wire side so as to provide connections with the trolley wire by means of the wire R. Aside from the modified form of the yokes and the angle plates forming the roof of the conduit, the details of construction are the same as in regular cable conduit work.

The single-trolley wire plan with overrunning contact has been selected as being the more simple and less expensive to construct. In such a device we have no contraction and expansion to take care of; the sags in the wire do that automatically. The insulating supports can be placed at a greater distance apart and need not be made so strong as would be required for heavy bars. The overrunnnig contact has the advantage of a direct line of mechanical connection with the car and also an advantage in not requiring wide gaps in the trolley wire at crossings and junctions and in being easily removed from the conduit.

The grooved trolley wheel is rejected, and in place thereof is substituted a cylindrical trolley wheel or roller W, some 4 inches wide at its periphery. By doing away with flanges on the trolley wheel we are also able to do away with deep grooves at frogs and crossings, and thus not only simplify the entire line structure, but get rid of two evils which cause the displacement of the running contact. The trolley roller has ample vertical movement but no lateral movement, it being made wide enough to always be in contact with the trolley wire.

Manholes H with covers M, Fig. 1, are placed at suitable intervals of, say, 20 feet apart in which are fixed the insulated supports for the trolley wire. The insulated support consists of a bar B, sustained by two insulators I I attached to the side of the manhole. One end of the bar B projects into the conduit and supports the trolley wire by means of the usual fixture device.



FIGS. 1 AND 2.—HEWETT'S ELECTRIC RAILWAY CONDUIT TROLLEY SYSTEM.

The trolley wheel or roller W, Fig. 2, is mounted on the end of the lever L, the other end of which is attached to the rectangular carrying frame by means of the fulcrum P and insulated block A. This lever permits the trolley wheel to move freely in a vertical direction so as to conform to the sags in the trolley wire, but does not permit any lateral motion as it is not needed, the roller having sufficient face to always be in contact with trolley wire.

The rectangular carrying frame shown in the longitudinal section, Fig. 2, is composed of two horizontal bars D G joined together by two vertical bars C¹ C², which pass through the slot. The upper bar D is extended the full length of the truck frame and at its ends are fixed two short cross-bars, one of which is shown at E, Fig. 1. The four ends of these short cross-bars rest loosely in four guides attached to the four corners of the truck frame. The guides are shown at F F, Fig. 1, and F² F³, Fig. 2. Two vertical bars C¹ C² are used instead of one, so as to get a more perfect guiding action of the slot independent of the car. The two vertical bars C¹ C² are placed directly under the axles of the wheels so as to have as little lateral variation as possible. The four guides F F F² F³ maintain the trolley frame in a vertical position, but permit it to be guided laterally by the slot and vertical guides c^1 c^2. The whole forms a trolley frame or carrier flexibly connected to the truck frame and guided entirely by the slot. It is easily detachable by withdrawing two pins N N from the guides at either end.

---

[1] See The Electrical Engineer, Sept. 21, page 262.

Electrical connection is effected by means of an insulated wire leading from the lever L through protecting tubes Q attached to the inner edges of the vertical bar c^1 thence along the bar D across bar E by wire K^2 K^3 to a spring-snap connection (not shown) on the car floor.

In changing from conduit to overhead wire two pins N N are withdrawn from the guide boxes on the rear end of the truck frame, the spring-snap connection pulled out and the trolley frame blocked fast to the track; then by putting the trolley arm on the overhead wire the car can move on, leaving the trolley frame behind. The frame slips out of the guide boxes and drops down on the slot rails, when it can be switched over to the in-bound track ready to be picked up by the next in-bound car, it being mounted on suitable lifts so as to slide directly into the guide boxes as the car runs over it. The retaining pins can then be replaced, the spring-snap connection restored, and the trolley arm secured, when the car is ready to move forward on the conduit line.

In case of obstruction to traffic the trolley frame can be dropped off, lifted out of the conduit through slot rail gates and transferred to the other track, where it can be picked up by the motor car on the return trip. The trolley device runs in either direction without readjustment and is readily adapted to either a loop terminus or a switch-over terminus.

In case of breaking of the trolley wire, the trolley roller W drops down below the supports B and passes on without injury. Trolley wire repairs are made by splicing in a new section from one manhole to the other. Cylindrical splices are not necessary. A simple plate splice will answer. Where cable gaps are to be crossed, two rollers attached tandem to the same lever will pass with ease and without interruption to the current. With this form of trolley wheel turnouts and crossings are more simple than with the grooved wheel. The grooved frog gives place to a simple plate frog.

The insulators I I are a special form of oil insulator in which oil is fed through the porous part of the insulator and runs off on the inner surface of the cell, thus constantly cleaning and renewing the oil film on the inner surface of the cell. Oil is supplied from a cup formed into the top of the insulator.[1]

In case of inadequate sewerage, and where there is no possible way to prevent the overflow of the conduit, a short section of overhead trolley wire can be erected for use whenever necessary. The trolley wire sections need not greatly exceed the length of the section of conduit subject to the overflow, which in most cases would be short—say one block. The conduit trolley wire should of course be switched out of circuit during such overflow. The same switches can also be arranged to switch the overhead trolley wire into service, the overhead trolley arm being put up while on the overhead trolley section. The conduit trolley runs idle through the water and comes into circuit again when the overhead trolley arm leaves the overhead trolley wire. The overhead trolley wire overlaps the conduit wire so as to leave no break in the motor circuit. The insulated blocks in the conduit trolley can be made of such material as oiled wood or porcelain so as not to absorb moisture while passing through water.

MR. HENRY ALBERT, electrical engineer, has accepted a position as superintendent of the Royal Light, Heat & Power Co. of Front Royal, Va. Mr. Albert has had a large experience, including work in South America.

"ON THE PROSPECT OF STORAGE BATTERIES FOR ELECTRIC TRACTION."

BY

G. Herbert Condict.

IN your issue of Sept. 14, "Gautherot," under the above heading, gives a very clear statement of the present condition of affairs in the storage battery field. The questions asked are of increasing interest to railway men, whose anxiety to obtain economical and unobjectionable power for their street cars is growing day by day. It is most unfortunate that during the last few years so many "new systems" have blossomed out in all the glories of new paint and a most commendable determination "to revolutionize the street railway world," only to be relegated, after a short and not altogether brilliant career, to the realm of the already well-filled past.

The fact that the running of one car "successfully" on a street railway track occasionally, for two or three weeks or months, does *not* demonstrate that a certain "system" is a grand and unqualified success, ought not to require proof at this late day. And yet, less than a month ago, the manager of an electrical company (which, by the way, has been "just about to close large contracts for storage battery car equipments" for some months past) stated that street railways could be operated at a cost nearly sixty per cent. less by his system than by horses, because he had "made most careful and trustworthy estimates, based on figures obtained during the running of a car equipped with this system, on a trial trip around the streets of" a certain city! When the "practical, substantial business men," who are furnishing the hard coin to support the above claim, wake up to the fact that estimates of this character are of about as much value as the paper on which they are written, there will be added to the long list of "fleeced lambs" another contingent. If only the ignorant, and sometimes unprincipled, promoters of such schemes suffered for such failures, very few tears would be shed over the matter, but those who are earnestly and conscientiously striving to solve the problem are so often included in the general condemnation, that it is of great detriment to the whole business.

There are batteries and batteries, many of which have undoubtedly failed to perform what was required of them. There are also other types, by the aid of which the question of storage battery traction will be settled satisfactorily and beyond all doubt. This will be accomplished by the employment either of such durable construction that long life may be guaranteed, or of such simple and cheap construction that renewals may be made at slight cost.

That the complex condition of patent litigation, which has been going on for so long a time, has been one of the worst obstacles in the path of storage battery progress, cannot be doubted. The "ample faith," which "Gautherot" speaks of, is not only dependent on the successful performance of the system, but also on the probability that capitalists will be able to call their own, that on which they have spent money. This part of the question can only be settled by the decisions of the law courts, or by a combination of interests.

Another factor in this slow development is, that generally when real, *serious* operations are to be commenced, a line is selected on which the service is exceptionally severe, owing to difficult grades, poor track equipment, excessively heavy traffic, etc. Undoubtedly the successful system must finally be able to cope with all such difficulties, but it is only reasonable to take hold of the less difficult tasks and then, as experience is gained, grapple with the greater. Because the trolley system grappled with some of the hardest possible conditions in its very infancy, is no reason why the storage battery should be developed along the same lines. In spite of all these obstacles the outlook is good; and so let the "patient public" be patient a little longer—let them take heart and expect soon to see a realization of their fondest hopes.

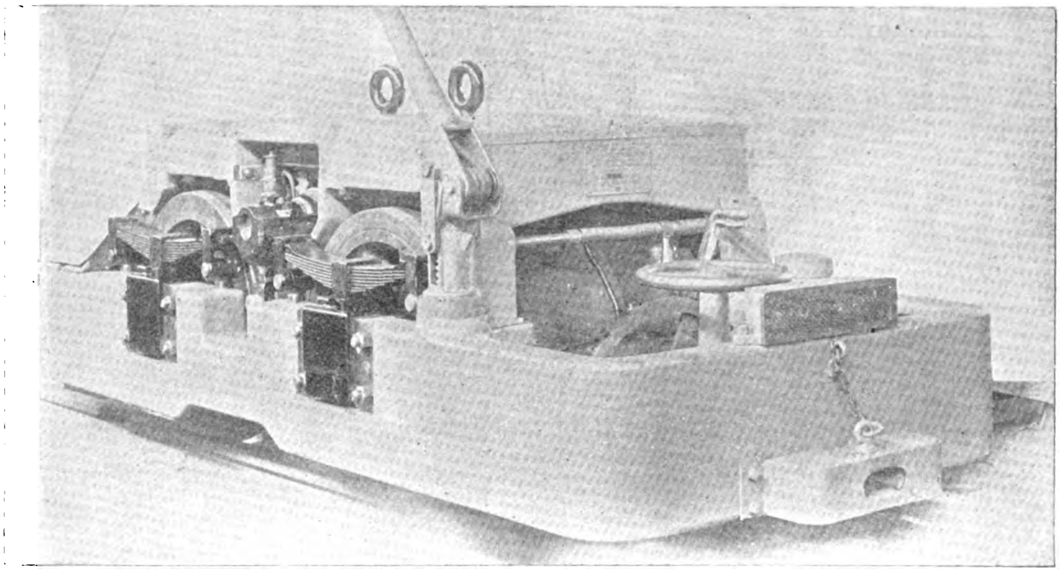
---

[1] A complete description of this insulator is given in THE ELECTRICAL ENGINEER of March 30 and May 18, 1892.

THE NEW "GENERAL ELECTRIC" MINING LOCOMOTIVE.

We illustrate on this page a new and compact form of electric mining locomotive, introduced by the General Electric Co. It is intended to operate in very low and narrow entries.

The frame consists of a single, heavy, box-shaped casting with recesses in the sides for the axle-boxes. Space is allowed at one end for the operating platform, and at the other end for the rheostat, the motor being placed in the centre. Recesses are also provided in the frame casting for the brake levers and axle gears. The motor is of a type similar to the "W. P." railway motor, and consists essentially of two main castings. The lower casting forms the lower pole-piece, and supports the bearings for the armature shaft, the two intermediate shafts, placed one on each side of the armature, and the field spool. The gears are set in pockets in the frame of the motor, and are completely and tightly covered by the iron castings, thus doing away with the separate gear cases. The top pole piece is part of the upper casting of the motor, and makes a complete cover for it, thoroughly protecting the armature, field spool and other interior parts. The armature itself is of the iron-clad ring type. The two intermediate shafts are placed on each side of the armature, and transmit power directly to both axles. The axle gears are set in fixed bearings supported by the frame of the locomotive, and are fastened to the axle by a flexible coupling of novel design, which allows free movement of the axle in all directions, except a longitudinal one, with reference to the gear and frame. This coupling is built entirely of heavy steel castings, with gun metal linings, so that it will easily withstand the rough wear and tear of mining service.



New "General Electric" Mining Locomotive.

The locomotive is equipped with a new and very simple form of trolley, insulated so that the operator may take hold of it at any part except at the wheel. In case it is necessary to move the trolley wire from one side of the entry to the other, the trolley may be lifted entire from its socket and placed in a corresponding socket on the opposite side of the locomotive.

All connections are automatically made by simply setting the trolley in place. The rheostat used is of the standard railway type provided with a special filling. The brake is a toggle joint made of substantial steel castings. The locomotive is also equipped with headlights and sand boxes. The general dimensions of the 30-6 and 30-10 locomotives as made for a 30-inch gauge are: Draw-bar pull, 3,000 pounds; speed, 6 to 10 miles per hour; length over all,9 feet 6 inches; total height, 36 inches; width over all, 48 inches; wheel base, 40 inches; gauge, 30 inches; diameter of wheels, 28 inches; weight, 15,000 pounds. The same type of machine is made of different capacities, with draw-bar pulls varying from 750 to 4,500 pounds. The locomotive is known as the "G. L. M."

AN ELECTRIC SHUNTING ENGINE.

Messrs. Mather & Platt, of Salford, England, have recently constructed a heavy electric locomotive for use at some large iron works in Sweden. This locomotive is designed to work with an E. M. F. of about 300 volts, and in external appearance is similar to those on the City and South London Railway. The motor is of the double armature type, the motors being connected to the axles through 10 to 1 spur gearing. An overhead wire, 16 feet from the rails, furnishes the current, the collectors consisting of an iron bar at each end of the locomotive, carried on upright pipe pillars.

THE NEFTEL & MARSH CO.

The Neftel & Marsh Co., of 126 Liberty street, New York, has just completed a reconstruction of the electrc line of the Camden Horse Railroad; also the extension of the service to Merchantville. This piece of work was of a difficult and novel nature. The road was previously operated with a two-wire overhead system, and at a potential of 120 volts. The present road is a single-wire 500-volt line, with Westinghouse motors. The change in line work and motors was made without any accident and without stopping the operation of the line; the only time when work was possible without current on the wires was from midnight until 5 a. m. Mr. J. Stanford Brown had immediate charge of this work.

The same company is now installing the electric light plant for the Green Island Electric Light Company, of Green Island, New York, with a capacity of 150 arc and 2,500 incandescent lamps.

DEWEY'S ELECTRIC HEATERS AND RESISTANCES.

ELECTRIC heating is yet in its infancy, but there has been sufficient experience in the use of electricity for heating purposes to demonstrate beyond a doubt, that it is in many respects superior to all other methods of heating. The many great advantages derived by using electric heat, more than make up for the slight extra expense attending its use in places where the cost of current is high. It has been found that the cost for heating electric cars by electricity is even less, in some cases, than heating them with coal stoves, and in other cases the cost was about the same. Allowing that the cost is even somewhat greater, no electric railway company should hesitate to equip its cars with electric heaters when their advantages become fully known. Managers of street railways and others financially interested are always anxious to make passengers as comfortable as possible, and electric heaters, if properly constructed, will go a long way toward making them comfortable, and will increase the patronage of the road.

Stoves in houses are bad enough, but stoves in a car are much worse. They are dirty, disagreeable and unsatisfactory in almost every way. The smoke, gases and ashes are disagreeable and soon make the car dingy and unsightly. The coal stove heats the car more than is necessary in the immediate vicinity of the stove, often scorching and burning the car roof, while the temperature a few feet from the stove is too low. It does not heat the car equally. Electric heaters heat the car equally or uniformly because they are divided and placed in different parts of the car. Electric heaters take up no seat room, being placed under the seats or in the form of a grating upon the floor, while a coal stove occupies the seat room of one passenger. It is not necessary to remove the electric heaters from the car in the summer season as they are light and occupy no valuable space. This allows the car to be warmed on cool days and evenings in the spring and fall. Electric heaters are always ready to start and can be stopped in a moment, after which there is no expense. There are many days in the spring and fall when for several hours in the middle of the day it is too warm and uncomfortable when the stove is heated, but it is kept heated because the evening may be cool. An electric heater may be stopped and started so easily that it is not necessary to run it continually and waste heat. Electric heaters are perfectly safe while coal stoves are dangerous, often causing fires in the barn at night. Properly made, electric heaters are more durable than stoves, for the radiating surface is large and therefore does not have to be heated to a very high temperature which would consume the parts. Coal stoves require expensive fuel while electricity is generated from cheap coal. Electric heaters do not require close attention, thereby allowing conductors to attend to their other duties more closely.

Electric heaters for an ordinary sized car cost no more than a coal stove and take but three amperes of current on a 500 volt circuit. One watt will heat nearly one cubic foot of air space in a car, but will heat between one and one-half and two cubic feet of air space in a house.

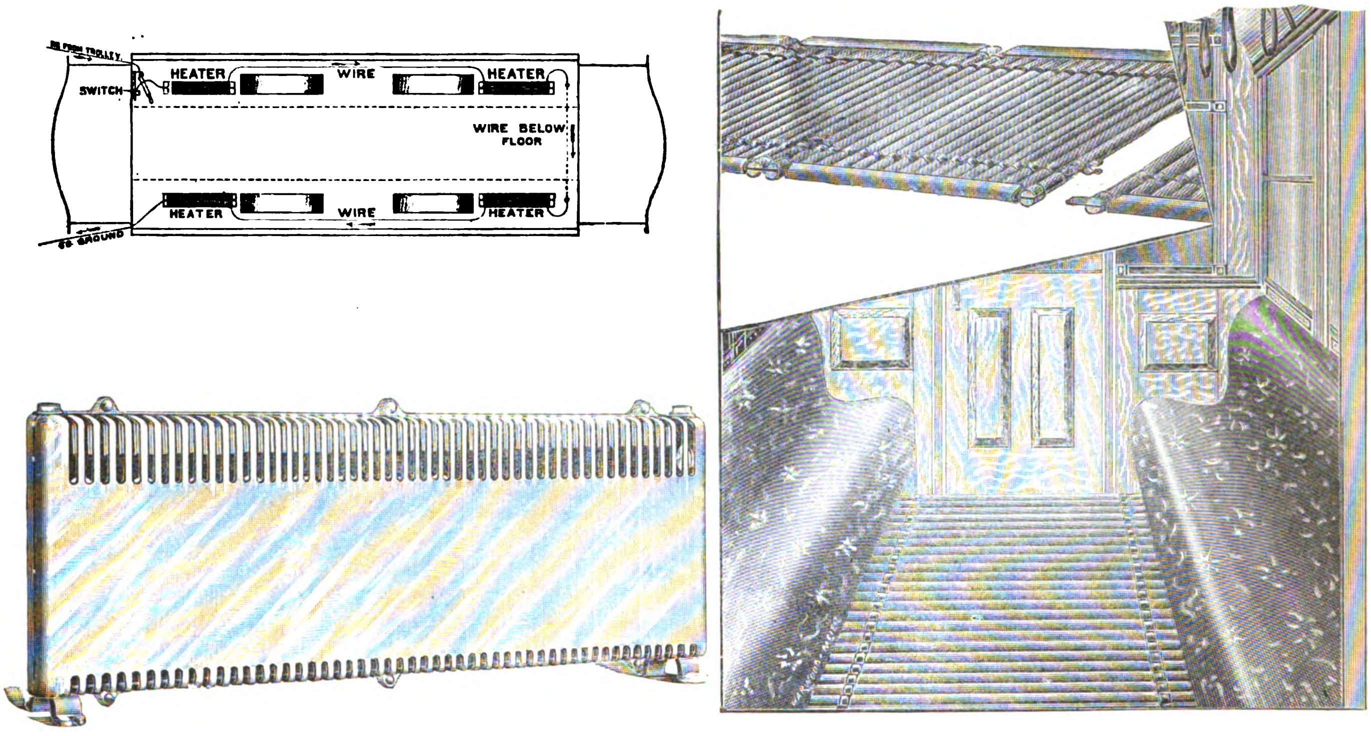
A building cannot be warmed so well and ventilated as thoroughly as by the proper use of electric heat, which is acknowledged by the best authorities to be the most healthful and perfect method. And the apparatus for its generation may be constructed to heat a single room or the largest building with a uniformity that cannot be attained by other methods. If it is not desirable to heat the entire house electrically it is certainly a most convenient way of heating a bath-room or sitting-room in the morning or evening in the spring and fall when the furnace is not running. With heaters for such purposes it would be unnecessary to run the furnace late in the spring or early in the fall and great economy would be derived and much trouble saved.

The electric heater is also better than a stove because it will not produce noxious gases, dirt and dust. The nearer we can get to the conditions of the radiant heat of the sun in warming a room the more healthful the heat will be. This can be best accomplished with electric heating apparatus having a large radiating surface that is not heated to a high temperature.

In the Dewey electric air heater the entire surface of the heating conductor is exposed to the air. It is supported and held firmly by non-combustible or fireproof material, and yet all except a very small per cent. of its surface area is exposed to the air. The case is slotted in the bottom and top, and the heat from the conductor causes the air to circulate rapidly through the case in contact with the heated conductor from which the heat is carried into the room. There is no chance of getting a shock, as all current-carrying parts are shielded and protected. No electric heater can be perfectly economical unless the air can circulate through it in contact with the heated conductor; no stationary solid substance, be it ever so good a conductor of heat, is equal to moving air as a distributor.

The principles just enunciated have been carried out in a variety of forms of Dewey heater, some of which we illustrate below.

Among these Fig. 1 represents one of Dewey's electric car heaters, from four to eight of which are necessary to heat a car, according to the size. The heater case is made of cast iron with a black japan finish. It is 26 inches long, 2 inches wide and less than 11 inches high, and it can be secured firmly to the floor. They weigh about twenty-five pounds each, and occupy but little room under the seats of the car so that they are not in the way. The heaters are generally connected in series on the car as shown in the diagram, Fig. 2. But one switch is in circuit to connect and disconnect the heaters, making their control simple and easy. At one end of the car the heaters may be joined by passing the connection through and beneath the floor as indicated in Fig. 2. Should extremely cold weather appear, one of the heaters may be short circuited if necessary in any suitable manner in order that a greater heat may be generated.



FIGS. 1, 2 AND 3.—THE DEWEY ELECTRIC CAR HEATERS.

Tin or zinc sheets may be secured to the woodwork of the car above and back of the heaters if desired. When the space beneath the seats is paneled in, the panels must be removed to permit the warm air to pass from the heaters into the car. Wire netting may be substituted for the panels if desired.

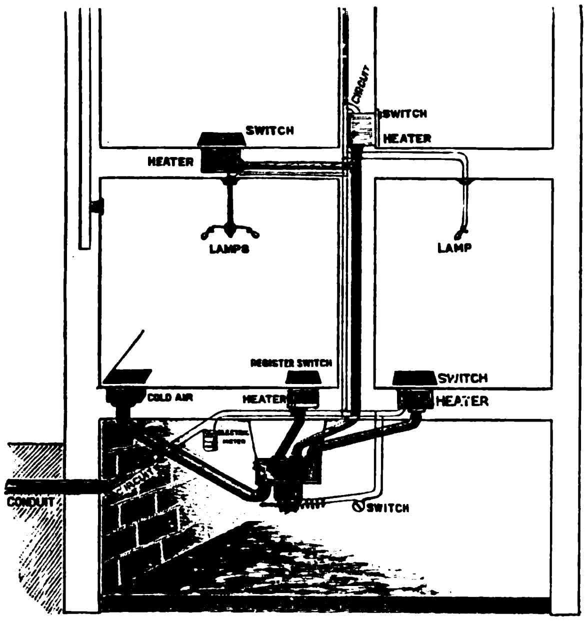


FIG. 5.—DEWEY'S SYSTEM OF ELECTRIC HEATING.

The same style of heaters are made wider than the car heaters for offices and other rooms so that one heater may contain more resistance and generate more heat. The two larger sizes kept in stock are about 7 and 12 inches wide, respectively. These heaters are furnished nickel-plated when so desired.

The Dewey grating or mat heater, shown in Fig. 3, is made in the form of a grating to lie upon the floor or aisle of a car. The grating is made of small gas pipe which encloses the conductor and forms a large radiating surface. The grating is made in sections and is easily removed for cleaning, and replaced. This heater is perfectly safe and durable, forming not only the heater for the car, but also the grating. It is not necessary to heat it above 120° F. at any time to warm the car, so that rubbers or leather will not be injured. It need not cover the entire floor, but only a portion of it, as at the ends of the car, so that it will not interfere with the opening of the trap doors over the motors.

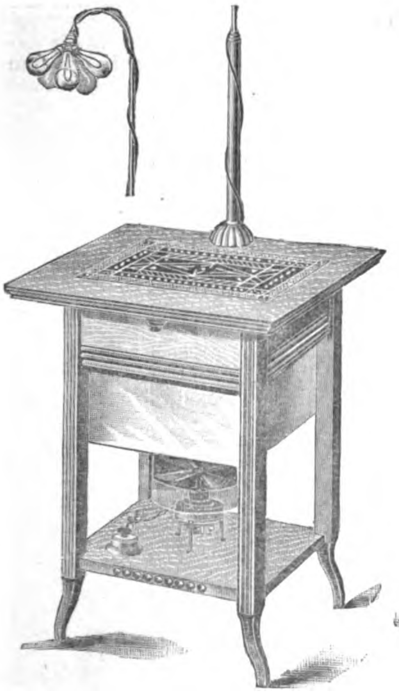

FIG. 4.—STAND AIR HEATER.

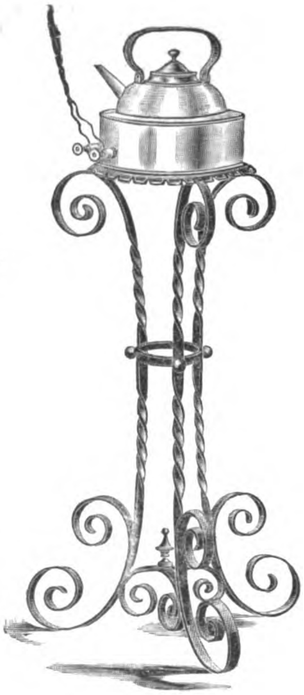

FIG. 6.—5 O'CLOCK TEA.

The Dewey stand air heater, shown in Fig. 4, is made of solid oak, and is highly finished with a beautiful nickel register in the top. The stand is 2 feet 6 inches high and the top is 2 feet square. One of the Dewey hot air heaters of a size sufficient to heat a large sized room, or two smaller ones, is arranged beneath the top in an enclosure of polished copper or nickel. A small fan motor is placed upon the lower shelf of the stand and forces the air of the room rapidly through the heater and register. This is a very rapid and even heater, and is especially adapted for heating a sitting-room or library on cool mornings and evenings in the spring and fall when the furnace is not running, or to supplement the furnace in extreme cold weather. Switches are provided for regulating the heat and the motor, so that they may be operated together, or separately and independently of each other, allowing the circulation of the air in the room in very warm weather when the electric heater is cut out. Several incandescent lamps are supported upon a polished metal fixture on the stand to give light to the room at night. The stand is light and easily moved when upon rollers.

The Dewey air heating system for houses is shown in Fig. 5. In this system the electric heaters are placed beneath registers in the floor or in the side of the room back of the base. Pipes lead from a drum, enclosing a fan operated by an electric motor in the basement or cellar, to the different heaters, so that air may be rapidly forced through them into the rooms, and another pipe is shown leading from a cold air register to the lower side of the drum so that cool air will be drawn from the rooms without taking the extreme cold air from outside. This fan may also be operated without the heaters and the heaters may be connected with the lamp circuit and operated independently of each other.

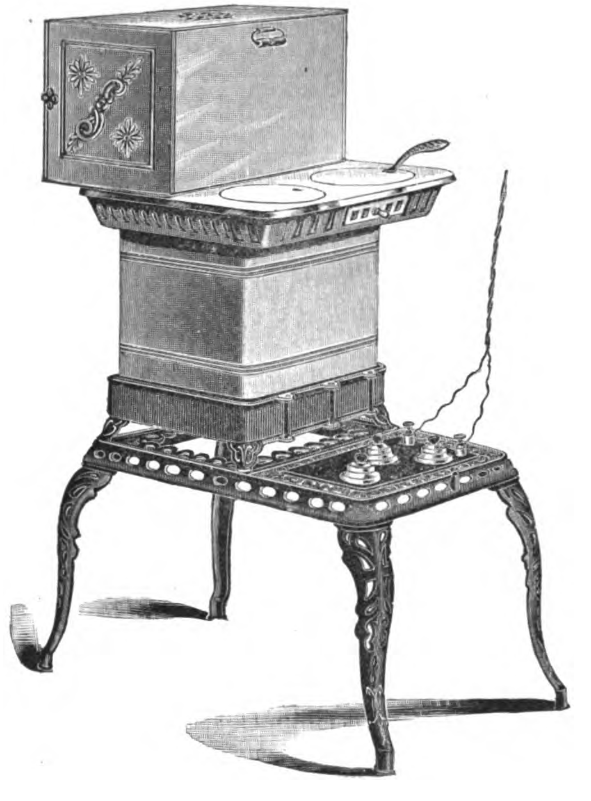

FIG. 7.—DEWEY ELECTRIC COOKING STOVE.

The Dewey kettle heater or "5 o'clock tea," is shown in Fig. 6, The stand is made of wrought iron painted black. The kettle and heater with terminals are of brass; the terminals are insulated from the heater case with porcelain, and asbestos is used to insulate the heating conductor so that there is nothing combustible about it. The heater may be attached by a flexible cord to a lamp socket, and is removable, that is, it may be taken from the stand and placed upon the table. The water will remain at scalding heat two hours after being brought to boiling point, after the current is cut off.

The electric cooking stove, Fig. 7, is three feet high without the oven, and has four griddles and a large double sheet iron oven which can be removed from the stove. It is perfectly safe and is easily controlled. Three different degrees of heat may be obtained by the small switches shown on the base in front. This stove is made for of any voltage.

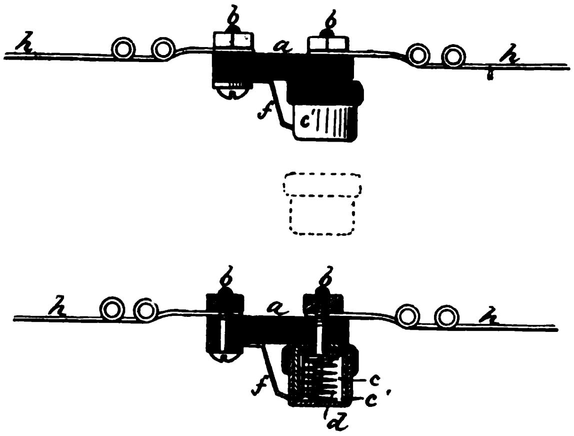
THE DENIO FIRE-ALARM SYSTEM.

BY

Jno. Dennis, Jr.

THE rapid advance in the utilization of electricity in fire service is well illustrated in the new auxiliary fire-alarm system, invented by William L. Denio and installed by the Standard Electric Signal Company, of Rochester, N. Y. In its auxiliary features the Standard Electric Auxiliary System performs functions never before attempted in the fire-alarm system. It is based on the value of quick, "still" alarms, which bring into service the particular fire apparatus which is most convenient to the locality, without alarming the remainder of the fire department unnecessarily.

In case of an alarm of fire, turned in either by manual signal box or a thermostat, the alarm is automatically sent into the fire house or houses on the auxiliary circuit, and the alarm is recorded in the fire department in 15 seconds, and in 22 seconds from the time of pulling the manual signal box or fusing the thermostat, the alarm is returned back to the building gong at the substation. All the auxiliary circuits run into one central station, which consists of a cabinet 2 feet square and 8 inches deep. In case of a service alarm, the number of the substation is recorded on the tape at the central station register, an alarm is given to the central station operator, and automatically sent to the fire house and back to the gong on the building. This alarm at the central station indicates, unerringly, whether the alarm was given by pulling a manual signal, or whether it was given by the fusing of one of the thermostats in the building circuit; thus furnishing an invaluable record for the guidance of fire underwriters.



FIGS. 2 AND 3.—THE DENIO THERMOSTATS.

An additional feature is that, in case of a broken wire in any of the building circuits the number of the box or substation will be recorded at the central station and an alarm given in the central station; thus indicating the location of the break. But no alarm will be given in the fire department; neither will the troublesome single stroke be sent into the fire department. Another valuable feature is the introduction of non-interfering street boxes, in any of the auxiliary circuits, which turn in an alarm to the central station through the same wires upon which the auxiliary substations are situated, and repeat into the fire department through the same central station instruments, as in case of an alarm from an auxiliary box.

The manner in which these various operations are carried out will be readily understood by referring to the accompanying engravings.

The central station consists of a register W, relay 18, sounder *r*, short-circuiting device Y, a return signaling apparatus I and necessary switches and gongs, and a gauge Z, Fig. 1. The substation consists of a signal box F, a building gong P, and wires through the different floors in the building, a manual signal box E and thermostats connected into the wires at desirable points, an automatic switching device, and a switchboard D for cutting out the different floors. The engine house equipment consists of a register and mechanical gong.

Beginning at the battery *h* at the central station, as shown in the diagram, Fig. 1, the circuit extends through wire 1 to binding post 2 to wire 3 and binding post 4 in the switchboard in the building to be protected. It passes around this switchboard and out through the different floors and through the manual boxes and thermostats back to binding post 8 in the switchboard; thence it passes over wire 9, to the base of the subsignal box, thence through the base of the subsignal box to the turning arm 10, to spring 11, to spring 12; thence along wire 13 to the binding post 14 at the building gong; thence taking the street wire 15 it goes into the central office through wire 51, entering the return signaling apparatus I through spring 16 which rests on the circumference of the break wheel *z*; thence through the metallic base of the return signaling apparatus I to wire 17, through wire 17 to the gauge X, and thence through wire 19 to the relay 18, back to the battery *h*; thus completing the normal circuit from the central station to the substation in the building.

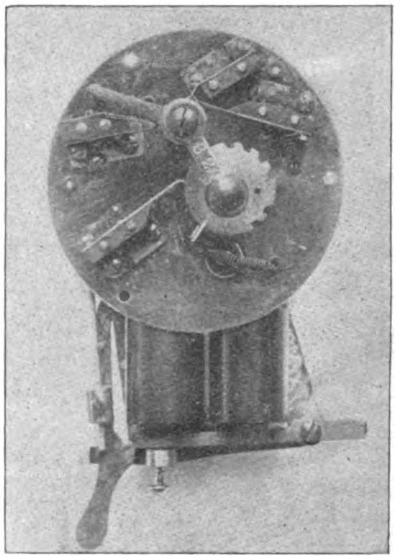


FIG. 6.—SUBSTATION SIGNAL BOX.

There is another battery *i* in the circuit from the central station to the building or substation 1. The course of the current over this circuit is from battery *i* through wire 23 to contact spring 24 in the sounder *r* (this contact spring, with its companion 26, is above and resting upon the armature of the magnets *q*). The current passes from contact spring 24 through the armature 25 (which is a conductor) through contact spring 26, wire 27, to and through magnet 28 (which is in the return signaling apparatus), thence through wire 29, which is the street wire from the central station to the engine house; thence through the gong and register at the engine house and through wire 30 to battery *i*, thus completing the circuit between the central station and the fire department.

Auxiliary to the circuit just described is another circuit extending from the battery *i* through wires 23 and 31 to the metallic spring 32. This is for the purpose of releasing the mechanism of the return signaling apparatus. From spring 32 the circuit extends from wire 31 up a hinged detent 32, along the escapement arm 33, to the base of the return signaling apparatus I; thence

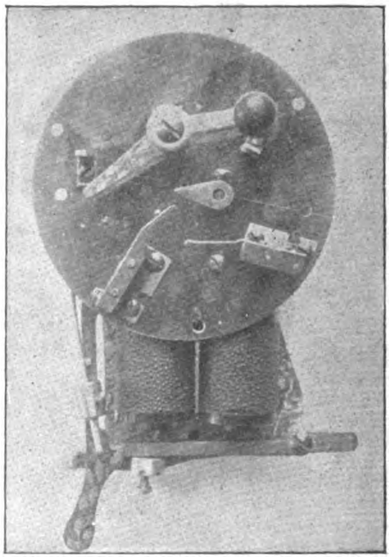

FIG. 4.—SHORT CIRCUITING DEVICE.

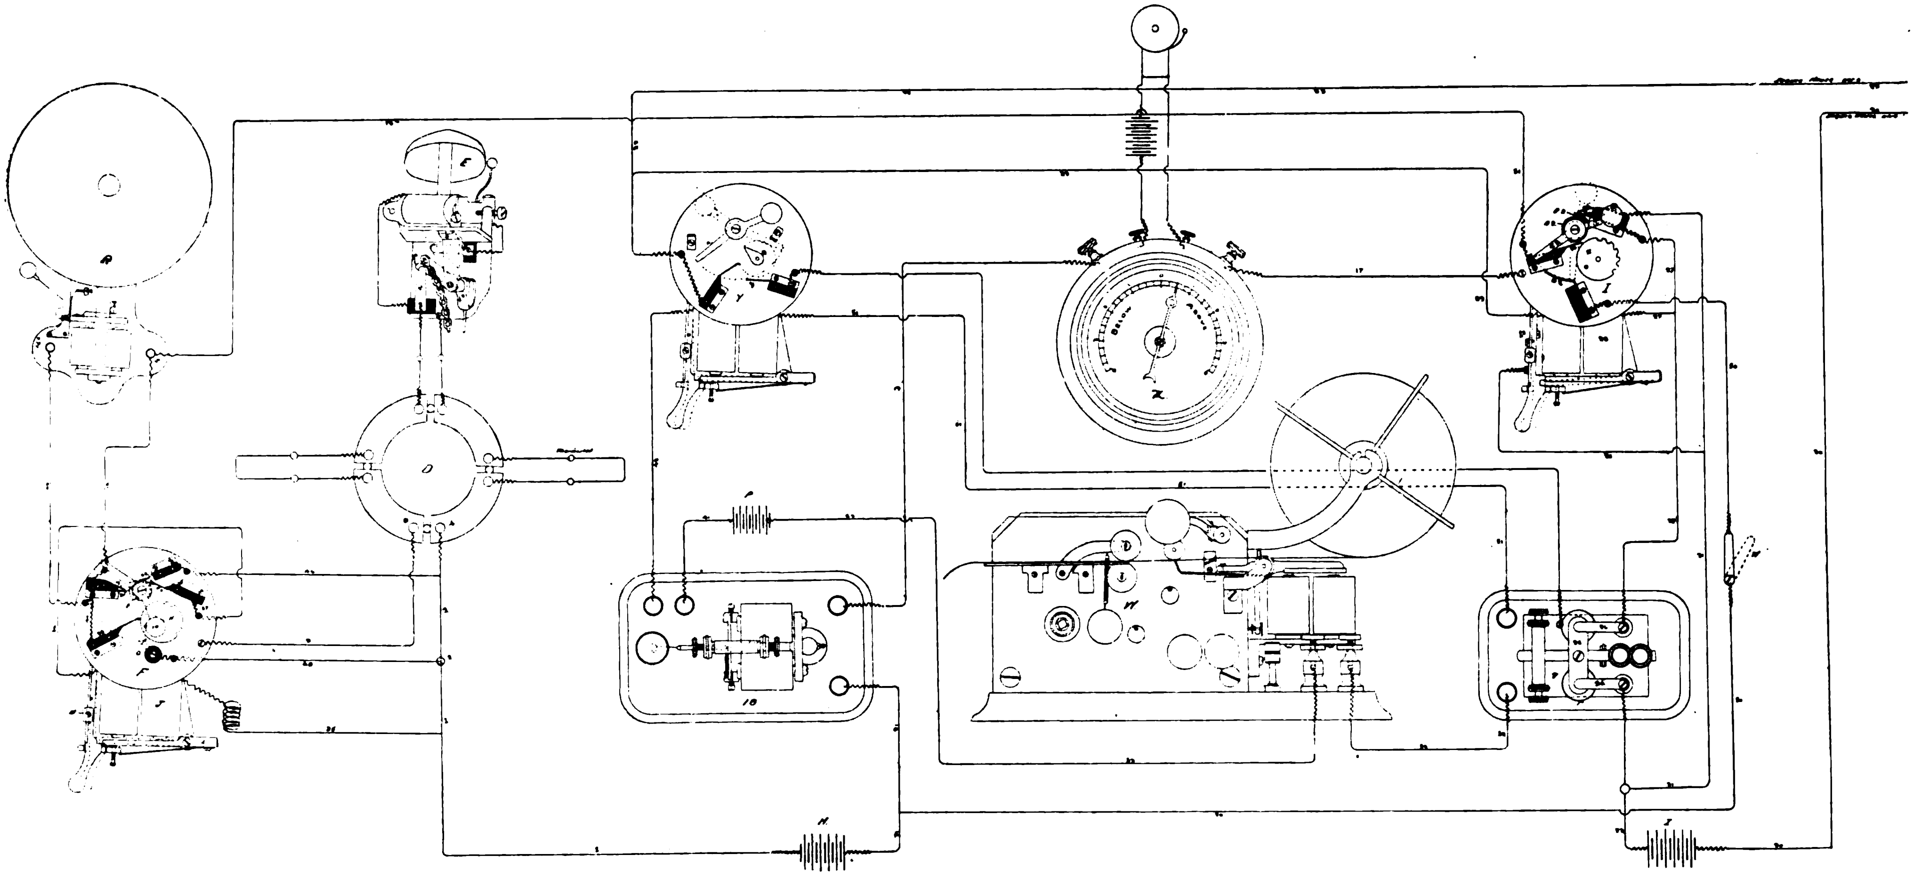

FIG. 1.—THE DENIO FIRE-ALARM SYSTEM.—

DIAGRAM OF CIRCUITS.

through wire 27 through the magnets 28 through wire 29 to the gong at the engine house and thence through wire 30 back to battery *i*.

It will be seen that the object of passing this auxiliary circuit through the return signaling apparatus is two-fold. It enables the alarm sent in from any substation signal box to be turned in to the fire-house, and also, after such alarm has been sent in to the fire-house to send a "return-signal" back to the building at which the substation signal box is located and from which the alarm emanated.

For convenience of reference, a top view has been shown of the relay magnet and sounder while a front view of the other apparatus is given. The wiring, which, for the same reason, is drawn on the face of the diagram, is of course on the back of the central station cabinet, which is only 2 feet square and 6 inches deep. It will be noted that the diagram drawings of the short-circuiting device Y, return signaling apparatus I, substation or manual box and manual signal box, are designed to be exact reproductions of the several pieces of apparatus shown in the engravings, Figs. 4, 5, 6 and 7.

The thermostat which is placed in such places in the building circuit as may be desired, is shown in Figs. 2 and 3. The thermostat, which is simply connected into the building wire, consists of an insulator *a* with two electrodes, *b b*, passing through it, to which the building wires are connected. To one of these electrodes or screws is fixed a metallic thimble, *c*, over which slides a movable thimble *c'* sweated on to the fixed thimble, without the use of acid by solder which fuses at 150 degrees Fahrenheit, or at any higher temperature that may be desired. Between these two thimbles is a coiled spring, which has power sufficient to throw off the outer thimble when the solder is fused in case of fire. A metallic spring *f*, forming a conductor, is attached to the opposite electrode and bears against the outside thimble, thus making the circuit from one end of the main wire to the other through the thermostat. A shoulder, *g*, made of rubber, vulcanized on to the outer thimble, is formed at its top. When the solder is fused and the outer thimble thrown off by means of the coiled spring in the interior, this shoulder strikes the spring *f*, and breaks the circuit at the moment the outer thimble is thrown off. When the outer thimble is off, the metal spring *f* flies back against the surface of the fixed inner thimble, thus re-establishing the circuit. The sliding of the outer thimble off the fixed thimble cleans its surface, so that the contact with the spring *f* with the inner thimble is always certain. It is by thus breaking the circuit that the signaling apparatus in the substation or building box is set in operation, as will be more fully described below.

The manual signal, which is also placed at convenience in the building wires, is provided with two springs 51 and 52 which rest in contact with the connecting bar 53, completing the circuit. n^2 is a snap switch operating the springs 51 and 52 to open the circuit of either. The object of the manual signal is to turn in an alarm by hand by opening and closing the circuit of the building wire in the same manner as by fusing the thermostat. The switch leaves the first spring, opens the circuit and then passes under the next spring and closes it. The magnet will not be charged until break wheel *n* in the substation or building box, in making its second revolution has left spring 45, at which time the short-circuit through wires 46 and 3 is cut out, and the circuit is established through the building again. The manual signal is operated by simply breaking a slender glass tube and drawing down a chain which it encloses.

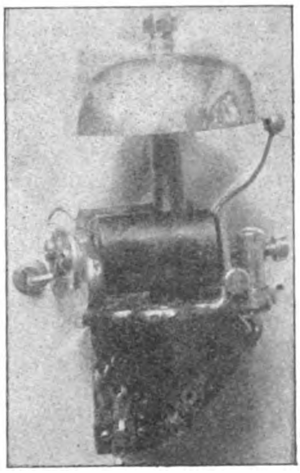

FIG. 7.—MANUAL SIGNAL BOX.

I have now described the normal condition of the system when ready for an alarm of fire. In case of fire, the fusing of the solder in the metal thermostat causes the outer thimble to be thrown off, thus opening and at once closing the circuit in the building. During this instant the circuit, which is then passing along wire 1, seeks a new escape. From binding post 2, instead of passing through the wires in the building, which are momentarily cut off, the current passes along wire 85, which forms a shunt, to and through a resistance coil in the substation box, and thence through the magnets J in the substation box, energizing them; thence it passes along wire 36 to spring 37 and thence to the swinging tongue 10, which is then in contact with spring 37, to spring 11 and thence by normal contact to spring 12 on to wire 13 to binding post 14. thence along the auxiliary wire 15 to wire 51, and thence through the central station apparatus, as before described, back to main battery *h*.

It will be noted, however, that the action of energizing the magnets in the substation box has released the signal machinery, and it has begun to operate During the brief interval while the circuit is broken by fusing the thermostat, or by operating the manual signal, the circuit through the building is cut out; but it is established again as soon as the new contact is made in either case, as described.

But the circuit does not pass through the service wires of the building again until the metal swinging arm 10 in the substation box after leaving spring 37 makes contact with spring 45 which forms a short circuit from spring 45 through wires 46 and 3 to binding post 2, thence through wire 1 to battery *h*; from battery *h* to wire 21 to relay 18 at the central station, wire 19 to gauge, wire 17, through the return signaling apparatus I through its break-wheel *z*, out through spring 16 which rests on the surface of break-wheel *z*; through wire 51 to auxiliary street wire 15, to the binding-post 14 at the building gong, through wire 13, springs 11 and 12, wire 40 to spring 38, to the brake-wheel *n*, to base of the substation, to the swinging arm 10, to spring 45, thus completing the circuit again. It is by this means that the circuit is maintained between the battery and the central station when the service wires in the building are cut out by the action of the thermostat or manual signal

During the instant that the current is broken in the building wires the charging of the subsignal's magnets draws up armature *l*. This armature holds normally an escapement *m*, which is thus released, and the substation mechanism begins to operate. The movement resembles in some minor respects an ordinary district movement. The contact spring 38 rests on the break-wheel *n*, which is notched for its particular number. On the shaft of this break-wheel is a metal tongue, 10. The entire substation apparatus is driven by a single time movement. When the movement of the break-wheel begins, this tongue shifts from the contact with spring 37 to contact with spring 45. The current is thus changed and now passes from the binding post 2, through wires 3 and 46, the spring 45, the metal base of the apparatus to the break-wheel. Thence it passes through the spring which rests on its notched rim through wire 40 into spring 11, and by contact into spring 12, and thence on the main line through wire 13 and the binding post 14 at the building gong. As the break-wheel continues to revolve, the spring, resting on its rim, engages with the notches which indicate the number of the substation. The result is that as the spring engages these notches the circuit is alternately opened and closed.

It will be seen by a glance at the diagram that this alternate breaking and making of the circuit will alternately demagnetize and magnetize the relay magnets 18 at the central station, and operate on the gauge with its connected gong and alarm bell in the central station cabinet, the relay 18 and gauge being in the main circuit. The demagnetizing of relay magnet 18 closes an independent local circuit in the central station.

This local circuit may be thus described: From battery *p*, through wire 41, to relay 18, wire 42 to magnets in the short-circuiting device, thence through wire 51 to sounder *r*, wire 52 to register and from register through wire 53 back to battery *p*. Opening and closing the local circuit has two effects. First it energizes the magnet *s* and releases the driving mechanism of the central office register and second, it alternately magnetizes and demagnetizes the magnet *q*. The office of the last-named magnet is to operate the sounder. At the same time it releases mechanism of the circuit closing device, which operates in unison with the mechanism of the substation box. This short-circuiting device is in the engine house circuit, and is provided with an arm *x* which revolves with the mechanism. As soon as the first number of the substation has been recorded on the tape on the central station register, arm *x* in the short-circuiting device comes in contact with contact point *y*. This contact momentarily makes a new circuit through the engine house gong, and momentarily short-circuits the magnet *j* in the return signaling apparatus allowing that apparatus to move during the second revolution of the break-wheel at the substation. The instant the arm *x* leaves contact point *y* the orginal circuit to the engine house through magnet 28 is restored, and the shunt circuit broken.

The return signaling apparatus, which is for the purpose of turning the alarm into the fire department and also for the purpose of afterwards repeating the alarm on the vibrating bell at the building or substation, has not yet been fully described. It consists of break-wheel *z*, similar to the break-wheel in the substation box, except that it is notched indifferently to cause an intermittent alarm on the building gong at the substation. Against the rim of the break-wheel rests a spring 16. There is a closing circuit insulated wheel, a^2, which revolves coincidentally with the break-wheel *z*, having on its side a lug b^2. The object of the lug, as will appear below, is simply to bring springs 46 and 47 in contact. There is a metal tongue c^2 attached to the shaft of the circuit closing wheel which revolves with it, and whose office it is in its revolution to strike an insulated spring d^2 and close a circuit.

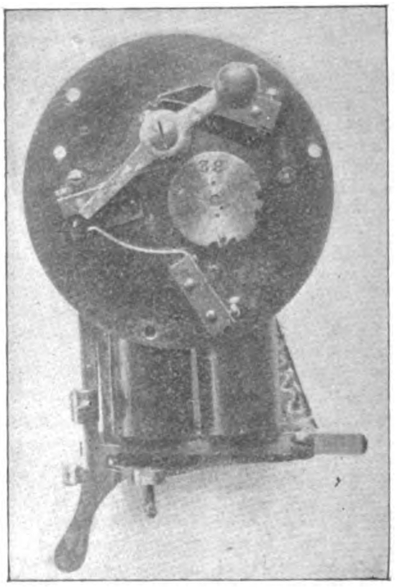

FIG. 5.—RETURN SIGNALING APPARATUS.

The signal is not repeated into the fire department during the first revolution of the break-wheel in the substation box, although during that first revolution, it is registered on the tape at the central station. During the second revolution of the break-wheel the operation is identically the same as during the first, excepting that the substation box has, by means of the return signaling apparatus, been placed in circuit with the fire department, into which it repeats its signal during the second revolution of the substation break-wheel. This is done by opening and closing the circuit at springs 24 and 26 (in the central station sounder), by the movement of the armature 25 up and down. The circuit to the fire department is then made from battery *i* through wire 23, spring 26, wire 27, magnets 28, wire 29 to engine house and wire 30 back to battery *i*.

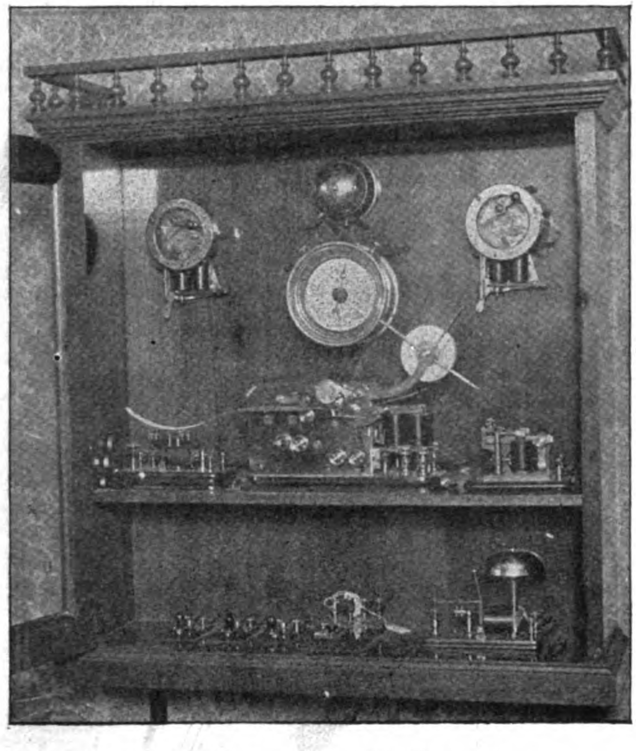

Fig. 8.—Central Station Apparatus.

While this action is taking place the break-wheel *z* and the circuit closing wheel in the return signaling apparatus are both revolving. Now, when the break-wheel *n* in the substation box has completed its second round, it comes to a stop, and its swinging tongue 10 strikes the contact spring *o* which is connected by wire 48. A new circuit is thus made through wire 48, spring *o*, swinging tongue 10 (which is in contact with the spring *o* at the time) and into spring 11 by the lug f^2 on the swinging tongue striking spring 11, breaking the circuit between springs 11 and 12; thence through wire 49, through the building gong, through the main line back to battery *h*. This short-circuits the service wires in the building. While this has been going on the circuit closing wheel a^2, in the return signaling apparatus, has turned sufficiently to bring lug b^2 in contact with spring 47, thus forcing spring 47 in contact with spring 46, and closing an additional shunt circuit from battery *i* through wires 27 and 31. This merely closes an additional circuit from battery *i*, the object of which is to prevent any alarm whatever being given in the fire house, unless it emanates from the break-wheel *n* in the substation box.

Now, the further revolution of the wheel a^2 in the return signaling apparatus, brings c^2 in connection with the insulated spring d^2. This makes a new circuit in which the current passes from battery *h*, through wire 21 and wire 50 to spring d^2 through the arm of c^2, (then in contact with d^2), through the shaft of wheel a^2, the base I, the break-wheel *z*, spring 16, wire 51 to wire 15, where it connects with the main circuit. This takes out the resistance of relay magnets 18 and gauge magnet. While the tongue c^2 is in contact with spring d^2, and the relay magnet 18 and gauge magnets are out of circuit, the break wheel *z* has come into position so that the notches in its rim act upon the spring 16 to alternately open and close the circuit and this sounds the vibrating gong P at the building or substation. The break-wheel *z* continues to revolve until the tongue strikes a stop on the break wheel when the movement stops, the tongue c^2 still remaining in contact with the spring d^2 and preserving the current. Under these conditions gong P will continue to ring until a switch, W, is opened to break the current. By this arrangement it is impossible to get a signal into the fire department except in case of fire, and when the signal is so given it is sure of being repeated to the building by sounding an alarm on gong P, showing that the fire department has been notified.

We will now illustrate the action of the apparatus in case of a broken wire instead of fire at the substation. In case the wire is broken at the substation, the current is permanently cut off from the building and not re-established, as in the case of the thermostat. The action is the same during the first round of the break-wheel *n*, as in the case of fire. The revolution of the break-wheel *n* operates the sounder *r* and registers the number at the central station, but during the second round of the break-wheel *n* a change takes place.

In case of fire the current through the service wires in the building is only momentarily cut off by the action of the thermostat and then re-established; but in case of a broken wire it is permanently cut off, and not re-established. During the first revolution of break-wheel *n* the swinging tongue 10 remains in contact with the curved spring 45, and maintains the circuit; but during the second revolution of the break-wheel the tongue 10 leaves the spring 45, and the whole current of the main line is cut off, until the tongue 10 strikes the contact spring *o*, when it is re-established. Consequently magnets 18 are demagnetized, the local battery *p* is closed, the magnet *q* is energized, the armature of the sounder *r* is drawn down permanently and does not vibrate, as in case of fire, and a vibrating alarm is given at the central station and the number recorded. The action of drawing down the armature 25 separates it from the contact springs 24 and 26. In such case the shunt current through the return signaling apparatus is not broken; consequently the current through the fire department is not interrupted and no alarm will be sounded at that point.

The apparatus is manufactured by the Standard Electric Signal Company, Nos. 31 and 32 Smith's Arcade, Rochester, N. Y. The officers of the company are: C. H. Blakeslee, president; George A. Benton, vice-president, and C. C. Hicks, secretary and treasurer.

THE KINSMAN RAILWAY BLOCK SYSTEM.

Year after year improvements have been made in the construction, equipment and management of railroads. In every department wonderful advances have been made. The link and pin have given way to the automatic coupler, which, with its strong platform and the vestibuling arrangements, have made telescoping almost an impossibility; the strap rail and the light iron tee rail have been superseded by heavy steel rails laid upon roadways which are marvels of engineering skill in alignment, grades and construction; the wonderful air-brake has superseded the weak and inefficient hand-brake; the movement of trains is regulated by telegraph from central dispatching offices, where formerly trains ran on chance; and on the best roads expensive and ingenious signaling systems have been put in use.

But, notwithstanding all these improvements, our railroads are still liable to dreadful accidents due to the fact that the trainmen are dependent upon their eyesight alone to determine when the conditions are favorable for the safe conduct of the trains committed to their care.

In order to render the safety of passengers independent of the vigilance of the engineer, the Kinsman Block System Company, of 143 Liberty street, New York, have introduced an apparatus, details of which are shown in the accompanying illustrations, devised with a view to stopping a train at any determined point without the intervention of the engineer, and 26 miles of railway near Chicago is now being equipped with the apparatus. The system is entirely automatic. When the visual signal is set at "danger" a current is thrown into a rail placed upon the sleepers opposite the signal post, and resembling an ordinary guard rail. When a train passes over this rail, electrical connection is established between it and an electromagnet in the cab of the locomotive which immediately closes the throttle and applies the air brakes upon the entire train. The apparatus for accomplishing

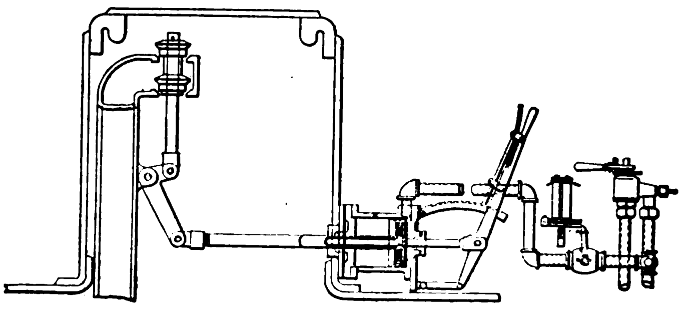

Fig. 1—The Kinsman Railway Block System.

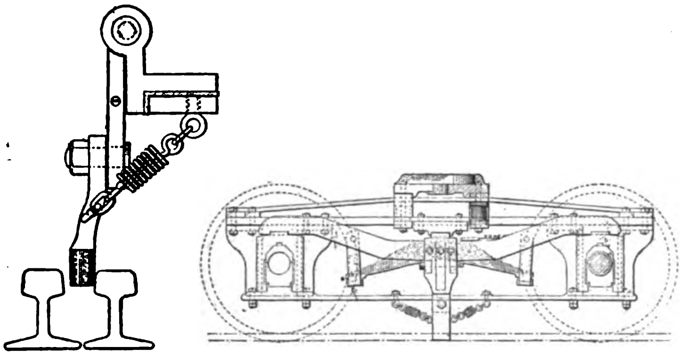
this is fixed between the throttle lever gland and the boiler head. The operation is shown in Fig. 1. When the air valve is opened by means of the trip actuated by the armature of the magnet, air is admitted to the cylinder surrounding the throttle lever spindle, its pressure forcing the piston to the left and closing the valve. The inner spindle, however, remains stationary, the outer portion of the sleeve being forced to slide upon the inner, while the air pressure overcomes the power of the springs that hold the piston against the inner spindle. The springs, four in number, are sufficiently strong to hold the two spindles together during all ordinary movements of the throttle by hand, and the throttle can, therefore, be kept locked at all times.



Figs. 2 and 3.—The Kinsman Railway Block System.

After the piston has been pushed beyond the port opening to the atmosphere in the upper side of the cylinder, the air escapes and applies the brakes, in the same manner as would the opening of the train pipe at any other place. This port is made of a size suitable to produce an ordinary application of the brakes. To provide for making a sudden stop, the size of this port is made adjustable so that it can at any time be instantly enlarged by the engineer, a light lever for this purpose being fixed where he can conveniently press it with his foot.

The electric rail is placed 1⅞ inch from the track rail, and the contact arm, shown in Figs. 2 and 3, is attached to the locomotive truck. This arm runs in the flangeway, and is therefore as free from danger of obstruction as the wheel itself.

The Kinsman block system can be used in connection with any kind of signals, and is capable of various modifications. The visual signal can also be dispensed with if desired. Tests extending over a period of nearly three years on the Peterboro and Shirley division of the Hoosac Tunnel route near Ayer Junction, Mass., show that the details of the apparatus have been carefully perfected.

THE SUCCESS ARC LAMP.

Of all the devices for utilizing the electric current the arc lamp in appearance was the crudest and clumsiest in design. Both consumers and manufacturers have begun to recognize this fact, and are demanding a lamp of graceful, compact design and handsome finish.

Especially is this true where the arc lamp is brought into close proximity and comparison with the artistic and beautiful fixtures used in incandescent lighting. What is wanted, evidently, is a lamp whose standard design is artistic and graceful and which shall cost no more than the present clumsy affair. With the object of fulfilling these conditions, Mr. S. L. Phillips, of No. 120 Liberty street, this city, has brought out the "Success" arc lamp, which has been designed specially to operate on incandescent circuits.

The lamp is illustrated in the accompanying engravings, Fig. 1 showing the type employed for inside lighting, which is ordinarily 36 inches long, but can, if required, be shortened to 22 inches. The lamp intended for outdoor use is shown in Fig. 2, being 32 inches long.

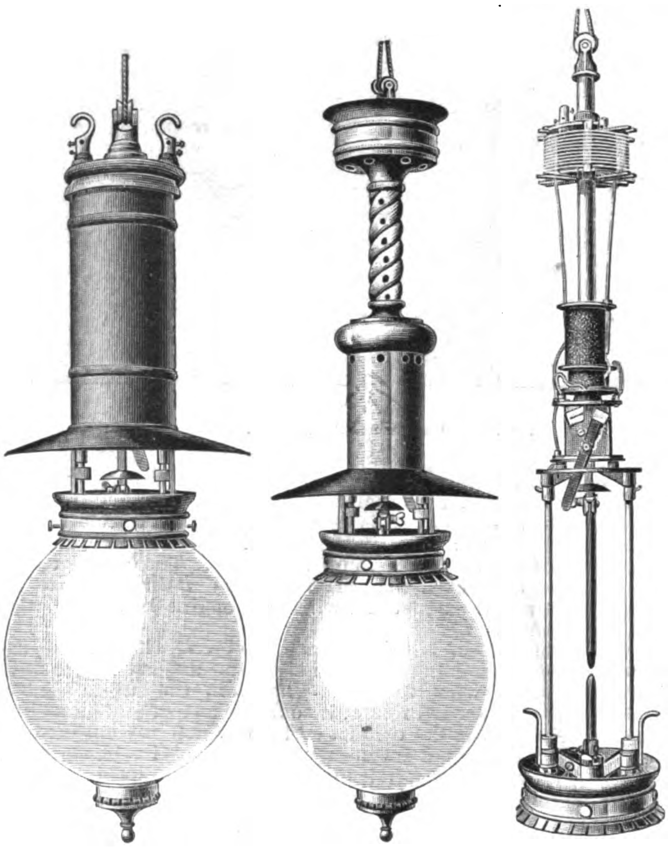
The mechanism of the lamp is clearly shown in Fig. 3. By a very ingenious device, the single 8-hour lamp is converted into a double or 14-hour lamp. This result is obtained by introducing a hollow lower carbon holder with a bayonet tripod cap. From this tube the lower carbon is fed upward, as the carbon burns away, by a spiral spring coiled beneath it.

The characteristic feature of the lamp is its simple mechanism, and the fact that no compensating springs, weights or dash pots are used. The carbon rack is fed by a simple clock train, and is raised or lowered by the difference in pull of the main and shunt coils. The carbons are normally separated and maintained so by the weight of the solenoid core, which has a pawl upon its lower end that plays into the teeth of the pinion and lifts the rack. When the current is turned on, the shunt coil lifts this core, releases the pinion, and the carbons come together; the main coil then immediately separates them and strikes the arc. The main and shunt coils are placed one above the other and the carbon rack passes through the centre of both of them, and through the core just described.

The lamp is wound with its proper resistance, and for isolated plants or electric railway circuits, where the potential is likely to vary, an extra resistance equal to the resistance of the arc is provided, which is automatically cut in, in case the lamp goes out, thus saving the shunt coil from burning out.

The lamp being wound for the voltage it is intended to be used on, and being a purely differential lamp, cannot get out of adjustment, and hence requires no regulating; and no means for regulating are provided, thus doing away with the possibility of derangement at the hands of trimmers and inexperienced men in the station. The insulation of the lamp is very complete, so that exposed parts can be readily handled, and the lamp itself is completely protected from grounds. The resistances are wound entirely upon fireproof material, and ventilated so that overheating cannot occur. Each lamp is provided with a specially designed and patented snap switch.

These lamps can be run singly, two in series, ten in series, or five in series from the outside wires of an Edison 3-wire circuit, and can be wound for any amperage, however low. They are nominally wound for 7 to 8 amperes and 45 volts.



Figs. 1, 2 and 3.—The "Success" Arc Lamp for Incandescent Circuits.

FRED. H. WHIPPLE AGAIN.

Some of our readers will remember the word of warning against the peculiar financial methods of Fred. H. Whipple printed in The Electrical Engineer of September 30, 1891. The following paragraph from the *Pittsfield Evening Journal* of September 26 is not without interest in that connection:

> Fred. H. Whipple was arraigned in the district court this morning for inducing Clarence G. Tompkins of this city to sign a $100 draft on false pretenses. On August 2, Whipple represented that he was authorized to draw on the funds of the Fred. H. Whipple Company at New York, and Mr. Tompkins signed the draft as an indorser and was just that amount out. A warrant for Whipple's arrest was recently sworn out, and Chief Nicholson hied him to Ohio after securing the necessary requisition papers. He returned this morning with Whipple in his custody. In court the case was postponed until Friday. Whipple was placed under $1,000 bail but didn't secure it. Congressman Crosby and Lawyer Wilcox will defend him. It is said that he secured money in a similar manner from two other Pittsfield people. The defendant engaged three lawyers and made a desperate attempt to defeat Chief Nicholson's effort to bring him to this city. His counsel offered to pay all expenses and all the money obtained if the case could be dropped. The court there sustained in every particular the view taken by Chief Nicholson.

Whipple's capture was effected in Cleveland.

G. A. R. ELECTRIC ILLUMINATIONS AT WASHINGTON.

THAT public fêtes and celebrations without electricity to enhance their splendor and give to them the necessary eclat, are becoming rare, has been very adequately proved during the recent gathering of the Veterans of the Grand Army at Washington. The celebration was to be so grand in the daylight, that for it to have failed in the evening, when, parades over, the visitors were free to promenade Washington's magnificent thoroughfares would have cast a serious reflection on the committee in charge. It was felt that electricity only would satisfactorily answer the purpose, and therefore it was adopted as the sole means by which a thoroughly brilliant illumination could be obtained.

To the Decorative Lamp Department of the General Electric Company, which distinguished itself at the Actors' Fund Fair last May, was confided the arduous task. The results elicited admiration and approval from every one, either visitor or resident.

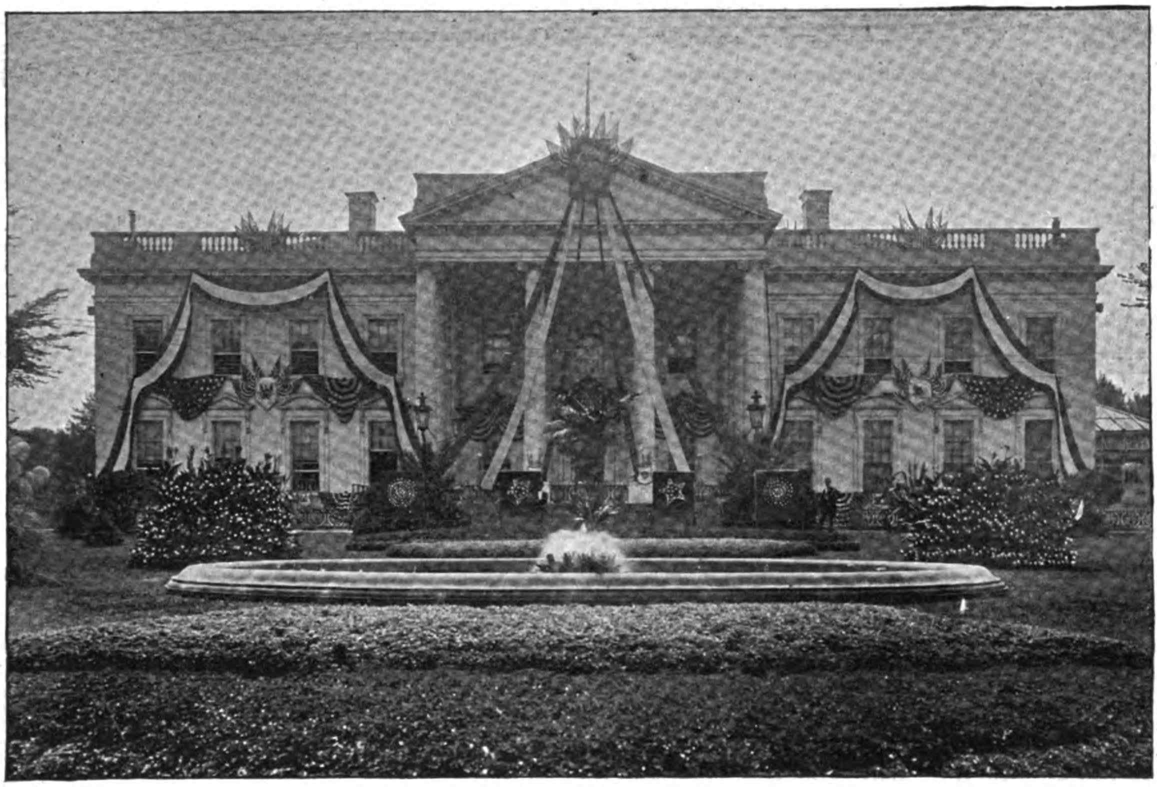
The interest in the reunion centered itself about Pennsylvania avenue, stretching from the White Capitol to the Treasury and the Executive Mansion, and it was determined that the electrical display should also be centered there. Running from near the Pennsylvania Railroad Depot to the Treasury, pole lines were erected on both sides of the avenue. At short intervals along these two lines different corps badges were designed in small but intensely brilliant incandescent lamps, each corps badge being repeated three times at various points on the avenue in the national colors of red, white and blue. Above each corps badge, the name of some notable fight in which the corps took conspicuous part, or well-remembered sojourning place during the war, was written in electric lamps. At rarer intervals the portraits in oil of the leading war generals were suspended, each surrounded by a double border, the inner one of very small lamps, the outer of lamps of a larger size and higher candle power.

At the corner of Tenth street, in front of the *Washington Post*, was erected a splendid anchor, about 20 feet high. When lighted it blazed so brilliantly as to make it the most attractive set piece on the avenue. In front of the *Washington Star*, twin stars of red and blue were placed, and a patriotic device gleamed from within the office windows.

At the head of the avenue at the entrance to the White Lot was erected the most conspicuous design of the occasion. It was a monster fac-simile of the G. A. R. badge, 18 feet high entirely made up of incandescent lamps. The eagle was outlined in white lamps, the cannon in blue, the stars and stripes in the regulation colors, and the pendant star in amber lamps. This piece was duplicated at the corner of Seventeenth street below the White House. From the Children's Stand, at the head of the avenue, the name of Lincoln, in white lights, evoked pathetic reminiscences from the veterans.

The illumination of the Treasury Building presented considerable difficulty. This was overcome by arranging along the cornice at the top of the fluted columns, a line of colored arc lamps, which stretched from the entrance to the White Lot almost entirely around the building. The red, white and blue globes of the lamps lent themselves admirably to the colors of the flags with which the building was hung. Colored arc lights were also used to illuminate the camp on the White Lot.

On the White House lawn, in front of the Mansion, a most fairylike effect was produced. Every bush, tree, fern and flower bed glistened with the light of innumerable miniature lamps, so suspended as to conceal all the mere practical details of installation. No less than 10 revolving stars, each of different design, were also set up here, constantly changing in design and color, reappearing and disappearing. Over each entrance to the Mansion was set a star of deep blue lamps. A marvelous effect, and one never yet essayed to add to the brilliancy of an illumination, was obtained by the introduction of the search light. On the roof of the Washington Loan and Trust Company's Building were set four 24-inch General Electric Company's projectors built at Middletown, three facing the Capitol and one facing the Monument. During the evening the brilliant rays of light from these projectors shot the national colors on the clouds, or illuminated the surroundings of the city. The most marvelous effects were obtained, however, when the whole four were brought to bear on the Capitol or on the Monument.



ELECTRICAL ILLUMINATION OF THE WHITE HOUSE, WASHINGTON, D. C.

All this remarkable display was not obtained without great effort. Less than 30 days elapsed between the commencement of the work and the illumination. Poles had to be erected, and a whole 3-wire system installed, drawing current from every available dynamo, public or private, in the city. In fact, not enough current could be procured.

Two G. A. R. badges, 68 corps badges, the same number of mottos and names, special devices such as the Anchor and Stars, had to be designed and executed. The streets had to be skilfully wired and socketed, the revolving wheels to be designed and constructed. Projectors had to be brought from the factory and erected. It was a great undertaking brought to a satisfactory termination. Some idea of the work can be gained from the fact that over 25,000 incandescent lamps were used in the illumination, as well as over 100 arc lamps.

Credit for the success of the illumination is to be rendered to Mr. A. D. Page, to whom *carte blanche* had been given, and to Mr. F. H. Clarke, the Washington representative, who were materially assisted by Mr. Fanshawe and Mr. McAllister, both skilful designers and versed in lamp requirements. The search lights were in charge of Mr. Gragg.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED SEPT. 20, 1892.

Accumulators :—

Storage Battery, E. R. Knowles, Brooklyn, N. Y., 482,979. Filed Oct. 15, 1891.

Employs a support plate for the absorptive material consisting of a central part provided with a connecting lug and downwardly turned flanges, and two outside parts; the flanges holding the three parts together.

Alarms and Signals :—

Electric Signaling Device for Firemen, G. L. Barnard, 482,778. Filed July 24, 1891.

A telegraphic signal between the pipeman at the nozzle of the hose and the engine tender.

Signal Telegraph, C. V. Boughton, Buffalo, N. Y., 482,780. Filed July 22, 1891.

A method of transmitting messages by sight by means of lamps whose relative positions and combinations indicate the different figures, letters or characters.

Dial Transmitter, F. Pearce, New York, N. Y., 482,877. Filed May 3, 1892.

A central station instrument for fire-alarm telegraphs giving facility to the operator for repeating the signal to a large number of circuits with comparatively small battery power and repeating the signals automatically.

Conductors, Conduits and Insulators :—

Composition Coating for Paper Tubes, S. Bergmann, New York, N. Y., 482,718. Filed March 4, 1891.

Claim: A coating for a tube or conduit consisting of a mixture of plumbago and plaster of paris.

Insulated Electric Wire, T. L. Reed, Providence, R. I., 482,753. Filed May 31, 1890.

Employs a textile wrapping filled with a composition of bitumen, wax and oxide or oxidizable oil.

Insulator, C. T. Lee, Boston, Mass., 482,872. Filed Nov. 14, 1891.

Employs an insulating block composed of sheets of mica pressed together, the block having a parallel sided seat and an outer shell partially enclosing it.

Insulator, H. H. Brooks, Cambridge, Mass., 482,913. Filed Oct. 26, 1891.

A tree insulator consisting of a cylinder of insulating material placed loosely in a holder having projections which partially enclose it and keep it in place.

Joint for Electric Conductors, J. W. Marsh, Pittsburgh, Pa., 483,074. Filed Dec. 21, 1891.

Employs a recessed supporting block of insulating material holding the adjacent ends of the corresponding conductors of the cable.

Dynamos and Motors :—

Armature Winding for Dynamo-Electric Machines, R. Eickemeyer, Yonkers, N. Y., 482,825. Filed Sept. 3, 1890.

A winding composed of strands of wire bent into various forms and constituting separate series, the strands of each set having a form peculiar to themselves and all secured in place by pins in holes in the ends of the armature cores.

Electric Locomotive, C. M. Conradson, Madison, Wis., 482,863. Filed Dec. 2, 1891.

Has for its object to combine the advantages of geared and gearless motors, and is so arranged that gears may be made use of where necessary, and their use discontinued where unnecessary, at will.

Alternating Current Motor, O. T. Bláthy, Buda-Pesth, Austria-Hungary, 482,974. Filed Dec. 7, 1891.

Employs two sets of field-magnet coils supplied from a source of simple alternating current and self-induction coils and condensers connected with the field magnet circuits by means of which the currents are displaced in phase.

Lamps and Appurtenances :

Suspension Bracket for Electric Lamps, T. Dillon, Indianapolis, Ind., 482,727. Filed July 9, 1892.

Carbon Holder, E. P. Warner, Chicago, Ill., 482,820. Filed Apr. 21, 1892.

A carbon holder having three points of contact for the carbon and a recess above the points whereby a swinging motion of the carbon in any direction is permitted.

Frame for Electric Arc Lamps, W. E. Bossert, Utica, and J. H. Findlay, Ogdensburg, N. Y., 482,940. Filed Oct. 24, 1891.

Electric Arc Lamp, J. A. Stuart, Philadelphia, Pa., 482,986. Filed July 20, 1891.

Has for its object to provide means for entirely relieving the regulating mechanism from the weight of the upper carbon holder of the first set of carbons in a duplex lamp when the second set is brought into use.

Attachment for Electric Lamps, J. Clift, Dorking, Eng., 483,044. Filed Mar. 2, 1892.

A reflector and holder for electric lamps.

Miscellaneous :—

Electrolytic Apparatus, T. Craney, Bay City, Mich., 482,724. Filed Jan. 2, 1892.

Employs an anode consisting of a body of carbon arranged to expose a number of separate horizontal surfaces, and a cell of non-conducting material enclosing the anode and having openings leading to the surfaces.

Means for Reducing Friction, G. M. Guerrant, New York, N. Y., 482,902. Filed Oct. 7, 1891.

Employs permanent magnets exerting attractive force upon a rotating shaft in a direction opposite to that of the weight-reducing friction upon the bearings.

Branding Stamp, J. S. Fitzmaurice, Sydney, New South Wales, 483,050. Filed Aug. 17, 1891.

An electric branding iron.

Electrical Stop-Valve, A. Franke, Berlin, Germany, 483,108. Filed May 6, 1892.

Game Apparatus, S. H. Johnson, Chicago, Ill., 483,115. Filed Oct. 5, 1891.

An electrical dice thrower.

Railways and Appliances :—

Conduit for Electric Railways, F. O. Blackwell, Boston, Mass., 482,719. Filed Dec. 4, 1890.

Claim 3 follows: In an electric railway conduit the combination of transverse yokes and an inverted channel-slot iron forming a shield over the supply conductor with an upright slot rail forming the other edge of the slot.

Electric Railway Conduit, R. M. Hunter, Philadelphia, Pa., 482,964. Filed Sept. 23, 1886.

A slotted conduit having an upper longitudinal compartment and a lower drainage compartment opening into one another, and a conductor carried on insulated supports in the upper compartment.

Closed Conduit for Electric Railways, L. P. Bunce, Minneapolis, Minn., 482,998. Filed Sept. 10, 1891.

Employs a supplemental conduit within the main conduit provided with a series of hinged plates closing the opening in the supplementary conduit when the trolley is not actually passing a given point.

Trolley Stand for Electric Railways, J. C. Hough, Pittsburgh, Pa., 483,061. Filed Dec. 21, 1891.

Employs a disc having helical springs upon its opposite sides in combination with a trolley pole socket forked to pass astride the disc and springs to engage alternately free of the springs.

Switches and Cut-Outs :—

Electric Switch and Case, A. Wright, Providence, R. I., 482,936. Filed May 31, 1892.

Consists of a shaft carrying contact blocks, an arm pivoted by links to guide blocks which are drawn together by springs forcing the contact block to the farthest point of rotation.

Circuit Switch, G. W. Russell, Jr. and D. B. Minor, Denver, Col., 483,123. Filed June 1, 1892.

Employs two solenoids placed end to end and connected by a brass tube in which is located a movable soft iron bar adapted to reciprocate as the current is passed through the helices, for the purpose of controlling any desired number of incandescent lamps from a distance.

SOCIETY AND CLUB NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

At the meeting of the council of the Institute, on Sept. 27th, the following 16 gentlemen were elected to associate membership:

Albright, H. Fleetwood, electrical engineer, Western Electric Co., 227 South Clinton street, Chicago, Ill.
Armstrong, Chas. G., electrical expert and electrical architect, 1301 Auditorium Tower, Chicago, Ill.
Callender, Romaine, electrician, Brantford Electrical Laboratory, Brantford, Canada.
Crandall, Chester D., assistant treasurer, Western Electric Co., 227 South Clinton street, Chicago, Ill.
Fisher, George E., general manager, Commercial Electric Co., 55–57 Gratiot avenue, Detroit, Mich.
Flesch, Charles, electrical engineer, Melbourne, Australia.
Jackson, J. P., assistant professor of electrical engineering, Penn. State College, State College, Pa.
Kinsman, Frank E., electrical engineer, Plainfield, N. J.
Magenis, James P., editor the *Adams Freeman*, Adams, Mass.
MacFadden, Carl K., chief electric light inspector, Chicago and Northwestern Railway Co., 22 Fifth avenue, Chicago, Ill.
McBride, James, superintendent, New York and Boston Dye Wood Co., 146 Kent street, Brooklyn, N. Y.,
Noll, Augustus, New York Electric Equipment Co., Duane street, New York City.
Ray, William D., electrician of local line of Northern Pacific R. R. Co., at Chicago, 308 Home avenue, Oak Park, Ill.
Rodgers, Howard S., electrical engineer, Thomson-Houston Electric Co., 624 Western avenue, Lynn, Mass.
Ross, Robert A., engineer in charge of engineering department Edison General Electric Co., Peterborough, Ont.
Smith, Frank Stuart, superintendent of carbon department Westinghouse Electric and Manufacturing Co., Pittsburgh, Pa.

At the evening session, a paper of the utmost interest and value was read by Mr. Chas. P. Steinmetz, on The Law of Hysteresis.

During the evening session the subjoined report of the committee on method of electing officers of the Institute was unanimously adopted, and became part of the constitution:

During the first week in February of each year the secretary shall mail to each full and associate member of the Institute a list of members; a list of the offices to be filled at the ensuing annual election in May, giving the names of the incumbents, and a copy of this rule, with the request that nominations, propositions and suggestions as to desirable candidates be made promptly and prior to March 1.

The secretary shall submit all answers to the Council, who during the month of March shall prepare a complete ticket to be headed "Council Nominees," containing the names of members whom they deem best suited, all circumstances considered, for the offices falling vacant. This ticket shall be printed on the same sheet with a "General Proposal List" containing the names of all eligible members proposed, with a memorandum stating the reason of ineligibility of all other names proposed, and with a statement that the nominations by the Council are in nowise governing, but are intended only to assist members in making a choice. The voting shall be restricted to the names on this sheet. This sheet, together with an envelope, on which shall be printed the address of the secretary, and the words "Voting Envelope—Enclosing a Ballot Only," shall, not later than the 15th of April, be mailed by the secretary to every member in good standing.

Each member may cast three votes for vice-presidents and he may cast all three votes for one candidate or two for one and one for a second, or one for each of three. Each member may cast four votes for managers, which he may in like manner divide between from one to four candidates. This division shall be specified by the appropriate numeral marked opposite the desired name.

All names voted for shall be written, printed or otherwise marked on a single ticket or ballot, which shall be enclosed in a sealed, unmarked and unidentified envelope of any suitable size, to be in its turn enclosed in the voting envelope received from the secretary. On this outer envelope the member shall add his signature, and the postage stamp.

At the annual meeting, these outer "Voting Envelopes" shall be opened in the meeting room by two tellers, then and there appointed by the presiding officer. After all the inner envelopes shall have been thoroughly commingled, they shall be opened and the votes shall be counted by the tellers, who shall report the results in writing. The eligible persons receiving the greatest number of votes for the respective offices shall be declared duly elected. The tellers shall reject all names that do not appear on the "Council Nominee" list or the "General Proposal" list, and they shall also reject that part of a ballot which shall name for any office or offices more candidates than there are vacancies.

This method of election shall apply to the offices of president, vice-president, treasurer and manager. No unsalaried officer except the president and treasurer shall be eligible to immediate re-election to the same office (as provided in Rule IV). The secretary and any other salaried officer shall be chosen each year from among the members of the Institute by the Council. The secretary shall be a member of Council, but shall have no vote in its proceedings.

CLEVELAND MEETING OF THE AMERICAN STREET RAILWAY ASSOCIATION.

SECRETARY W. J. RICHARDSON has issued his final circular letter with reference to the annual meeting which is to be held at Cleveland, Ohio, on October 19, 20 and 21, at Association Hall. The hotel headquarters will be the Hollenden. Railway fare at the special rate of a fare and a third for the round trip will be obtainable in the usual way.

The programme of the meeting will run as follows: *Reports of Special Committees.*—Special committees will report on the following subjects: "A Model Electric Street Railway Roadbed, and Underground Wiring;" "A Perfect Overhead Electric Construction;" "Economy of Machine Shops for Electric Street Railways;" "Power House Engines;" "Relative Cost of Operation of Horse, Cable and Electric Roads," and "Standards for Electric Street Railways." Notice has been received by the secretary that special papers will be read under the following titles: "Experiments on the Expansion of Continuous Rails," and "Is a Standard Rail Head Possible?" Upon the request of the executive committee, Mr. D. F. Longstreet has consented to prepare, and will read, a paper narrating the events which led up to the formation of the American Street Railway Association.

The local committee has secured ample accommodations for all who desire to exhibit their manufactures. Mr. H. J. Davies, secretary of the Brooklyn Street Railroad Company, of Cleveland, has special charge of this department.

The Cleveland Street Railway Companies, supplemented by the Short Electric Railway Company, propose to entertain all who attend the meeting, in a way to be remembered. The annual banquet will take place on the evening of Thursday, October 22.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

An advertisement benefits by the company it keeps.

MR. C. D. SHAIN TO REPRESENT SIEMENS & HALSKE IN THE EAST.

AS we go to press the intelligence reaches us that Mr. Chas. D. Shain, of 136 Liberty street, has been appointed to represent the Siemens & Halske Electric Co. of America, having charge of the Eastern agency. Owing to this important arrangement Mr. Shain will have charge of their business in the New England and Middle States, Virginia and West Virginia. Our columns, this week, illustrate some of the apparatus of the company, which has as high a reputation in Europe as Mr. Shain enjoys in this country. This business combination is a strikingly strong one.

W. R. BRIXEY AND KERITE.

THE following important notice has just been issued to the electrical trade, regarding the old and well-known "Kerite" insulated wires and cables, whose headquarters are at 203 Broadway, New York:

> Having succeeded to the celebrated Day's "Kerite" insulated wire and cable business, I beg to state that after a close and personal study, both as superintendent and general mannger for 14 years in the manufacture of the same, I am prepared to supply wires, cables and tapes of the highest standard.
>
> My personal experience in each part of this business enables me to meet the wants of customers in every detail, and I bespeak a continuance of favors so generously accorded in the past.
>
> Yours very truly,
> W. R. BRIXEY.

A host of friends will extend their good wishes to Mr. Brixey on this continuation of the business with which he has so long been prominently connected, and of which he now remains in sole control.

E. W. BLISS & CO., LIMITED.

THE above concern, of 17 Adams street, Brooklyn, N. Y., have been steadily adding a Western trade to their large Eastern business, and now have opened a store at 14 North Canal street, Chicago, where they will carry a representative line of presses, drop hammers and sheet-metal machinery. The store is situated at the centre of the machinery district of Chicago. Mr. C. W. Ellsworth, until recently superintendent of the Chicago Stamping Co., will be in charge, and will be ready to attend to orders for anything that pertains to punching, shearing, drawing, stamping, perforating, forging and embossing by means of machinery.

THE FORD-WASHBURN STORELECTRO COMPANY.

A VERY interesting pamphlet on their storage battery has been issued by the above company, of Cleveland, Ohio, where they have made some really remarkable demonstrations in street railway and other work. One novel feature of the cell is that it has a porous cup to hold the active material, as the result of which it will stand the severest short-circuits. The pamphlet says:

> Not only will the Ford-Washburn battery stand repeated discharges, in this way, on dead short-circuit, without injury, but it will remain in first-class condition for an indefinite period of time, when unused, on an open circuit. The company has had a fully equipped car running in Cleveland, Ohio, and the batteries have been frequently tested for the heaviest possible sudden discharge. In November, 1891, some 60 of the cells were taken out of the car and examined. They were found to be in good condition. The battery was then about half discharged. In May, 1892, they were examined again and found still in splendid condition. The other half was used experimentally in the same month of May, on incandescent lamps, and showed absolutely no falling off from disuse. This is only what might be expected. The heavy discharge cannot "buckle the plates" because there are none to buckle. All the expansion and contraction of the active material is taken up by the corrugated lead well in the cell, and there are no lozenges or plaques of active material to become loosened or dislodged, either when the cell is in use or when it is supposed to be standing in idle safety.

In addition to references to the many articles on the battery that have appeared in the technical journals, the pamphlet includes a number of testimonials from leading citizens of Cleveland and experts who have witnessed and tested the performance of the Ford-Washburn car.

J. JONES & SON.

A REPORT has been in circulation that this well-known firm are about to close up their business at 39 Vesey street. We are informed by them that this is erroneous. Contrary to such a step, have added to their business quarters by acquiring the controlling interest in a large and well-equipped machine shop at 60–62 Murray street, known as the J. M. Lambert Manufacturing Co., where their manufacturing will be carried on in the future.

The removal of this part of their business has left on their hands a well-fitted machine shop at 39 Vesey street for sale, which has no doubt given rise to the above report.

Not only are they able to offer better facilities by this move, to their customers in the manufacturing line, but they have more room and time to enlarge their supply and construction department at their old quarters, a part of their business which they are vigorously and successfully pushing.

THE UNITED STATES GOVERNMENT APPROVES THE RIES SOCKET.

THE subjoined is an interesting extract from the report of a test made at Mare Island Navy Yard, California, by Lieut. C. F. Pond, U. S. N., to the Naval Observatory, Washington, D. C.

> "Upon using the electric lights at the Transit Pier, one for illuminating the field of the transit, and one for reading the level and finding circle, as mentioned in the report of last year, it was found desirable to have lights which might upon occasion be reduced in intensity. To accomplish this end, two Ries regulating sockets were procured which perfectly fulfilled the purpose for which they were intended, allowing seven (7) distinct or different degrees of brightness, from simply a dim glow to the full power of the lamp. In fact, when fully turned on, the Ries regulating socket gives an intensity of about two (2) more candle power than is given by the ordinary socket. Two lamps with spiral filaments were procured, the filament of this lamp is short and well removed from the socket, thus giving off less heat, and the light is nearly all concentrated in the spiral, which gives a better illumination of the field, with a lesser intensity in the light, thus fulfilling all the requirements sought.
>
> It was suggested by the Ries Electric Specialty Co., of Baltimore, from whom the sockets were procured, that it might be advisable to separate the socket from the lamp, but as the socket generates no perceptible heat in itself. that was found unnecessary.
>
> The Ries regulating sockets are a very valuable adjunct in the use of electric lights in astronomical or other instrumental work. As now fitted, the electric lights at the Transit Pier are a very great convenience, a saving of time and trouble, not to mention the gain in neatness by doing away with the old oil lamps."
>
> Respectfully,
> LIEUT. CHAS. F. POND,
> Lieut. U. S. N.

F. P. LITTLE & CO.

THE above progressive firm of electrical engineers of Buffalo, N. Y., report that in addition to their other large contracts now on hand, they have just closed two more, of an important character; one with the Buffalo Furnace Co. for 31 arcs and 250 incandescents, and one for equipping the fine residence of Mr. G. V. Foreman on Delaware avenue, Buffalo, for a complete outfit of bells, speaking tubes and incandescent electric light wiring. The two contracts aggregate about $7,000.

METALLIC VACUUM PUMP LITIGATION.

THE BEACON VACUUM PUMP AND ELECTRICAL CO. have instituted proceedings for infringement of their patents on metallic vacuum pumps, against Berrenberg Bros. of Boston.

NEW ENGLAND NOTES.

The Westinghouse Electric and Manufacturing Company, through their Boston office, have recently made the following sales of railway apparatus: New Haven and West Haven Street Railway Company, New Haven, Conn., ten car equipments, each car having one 20 h. p. single-reduction motor; Norwich Street Railway Company, Norwich, Conn., three car equipments, consisting of two single reduction 20 h. p. motors for each car; Amesbury and Haverhill Street Railway Company, Amesbury, Mass., two car equipments of two 20 h. p. motors to each car; Worcester Consolidated Street Railway Company, Worcester, Mass., an addition to their Westinghouse system of two car equipments of 20 h. p. motors to each car; Hartford and Wethersfield Street Railway Company, Hartford, Conn , one 250 kilowatt generator, and two car equipments of two 30 h. p. motors to each car; Holyoke Street Railway Company, Holyoke, Mass., one car equipment consisting of two 20 h. p. motors.

Swan & Lane, of Boston, who commenced business about six months ago as general electrical engineers and contractors, have received lately a number of good contracts for wiring. Their most recent contract is one for a 300-light plant for the Mount Battie Woolen Mills, Camden, Me., where they will, in addition to the wiring, supply all the material, including a Jenney dynamo, for which they are New England agents. Mr. F. A. Swan has recently returned from Augusta, Me., where he has been personally superintending the wiring of the new opera house in that city, the finest theatre in the State of Maine. Five hundred lamps will be used, and Mr. Swan himself arranged the switchboard and dimmers for stage effects.

The Sawtell Company, of Boston, have opened offices at 243 Franklin street, for the sale of incandescent lamps of all voltages and candle power, and capped for all standard sockets. They are also equipped for the renewal of burned-out incandescent lamps, being the New England agents for the Davis Electrical Works, of Springfield Mass,, who have equipped a factory for this purpose. Burned-out lamps will be received and new filaments put in, and the renewed lamp returned, the Sawtell Company agreeing to do this at a considerably lower cost than the price of a new lamp. Mr. A. H. Sawtell is general manager of the company and will be glad to furnish all information.

The Young Men's Christian Association, of Boston, through their indefatigable secretary, Mr. James L. Gordon, are calling attention to their evening classes in electricity and other sciences. The class in electricity was opened for the first time last fall, and so great has been the success in this department that they are going to make this winter's class even more attractive.

The Berlin Iron Bridge Co., of East Berlin, Conn., are building a new machine shop for the Mather Electric Co., at South Manchester, Conn. The building will be 52 feet wide by 150 feet long, the central portion being 35 feet in width and controlled by a 15-ton traveling crane. The design is a combination of iron and wood, all the heavier parts of the building being of iron.

The Sawyer-Man Electric Co. have sold through their Boston office alone for the month of September over 25,000 lamps—probably the largest month's business they ever did in this territory.

CANADIAN NOTES.

Montreal Electric Railway.—The new management of the Montreal Street Railway Company, since August 1st, when work was begun, have been energetically pushing work on the introduction of the trolley system, and successfully inaugurated electric traction on September 21st, by the opening of a belt line of four miles of single track, extending from the centre of the city to the exhibition grounds. In addition, one of the old lines, that on St. Catherine street, consisting of four miles of double track, was equipped and in operation some ten days later. For present use the company has twenty motor cars of American manufacture and fifteen of Canadian make, besides which, for the complete equipment of all the lines, 100 cars have been ordered from the United States and a like quantity in Canada. These cars are to be equipped with two single-reduction motors of 25 h. p. each, of Royal Electric, Westinghouse, and Edison Companies' manufacture. The greater portion of these motors will be furnished by the Royal Electric Company, whose motors have given excellent results. No power house is to be built for the present, power being furnished in the meantime from the lighting stations of the Royal Electric Company.

The Central Electric Light Co., of Montreal, Limited, will apply for incorporation, with a capital of $500,000. The object of this company, of which Mr. Louis Perrault is chairman of the provisional directors, is to meet the increasing demand for electricity for light, heat and power. Its intention is to acquire the plant and business of the Perrault Electric Light and Power Co., and to equip, for the present, a station in a central locality of sufficient capacity to supply some 500 arc and 3,000 incandescent lights, besides electric power to the extent of 500 h. p. The company will tender for the lighting of the city of Montreal, the present contract for which expires next year, and, if successful, will largely increase the capacity of its station.

Mr. W. J. Morrison, who has so long represented the Fort Wayne Co. in Canada, has now removed from Toronto to Syracuse, where he will continue to look after and develop the large business that he has now built up in New York State, in the same apparatus.

NEW YORK NOTES.

W. S. Chesley & Co. owing to increased business, find it necessary to enlarge their quarters, and are now fitting up a new machine shop 50 x 75 at 24 Morris street, Jersey City, near Cortlandt Street Ferry, and will have facilities for repairing all kinds of electric light and power apparatus. It is the practice of this company to buy apparatus, outright or, if preferred, to receive it on consignment, repair it if necessary and sell it on commission at the owner's price. They also solicit the manufacture of electric appliances and specialities. They still retain their agency for the Easton Electric Company, of Brooklyn, who manufacture arc dynamos with automatic regulator, slow-speed incandescent dynamos and motors ; and they desire to employ salesmen.

The Union Railroad Company has put in operation a number of its trolley cars, of the Thomson-Houston make, within New York City limits, very successfully. The plant is equipped with four Thomson-Houston generators run by four Cooper-Corliss engines of 350 h. p. each and the station has room for 5,000 h. p. capacity of engine and dynamos. The station is situated on the Bronx River.

WESTERN NOTES.

The Central Electric Company are preparing an exhibition at their warerooms of Interior conduit and supplies, erecting a house complete, showing the method of wiring and the connections by junction boxes, etc. The exhibition will be interesting and practical.

D. A. Andrews, Jr., of Pettingell-Andrews Co., the prominent electrical supply dealers of Boston, Mass., was in Chicago recently, and a caller at the Western office of The Electrical Engineer.

Tracy H. Clark and Chas. S. Marshall of the firm of Clark & Marshall, No. 413 The Rookery, Chicago, have gone to St. Louis, Mo., on a business trip to show their many fine specialties.

Mr. Dwight B. Dean, of the McGuire Manufacturing Co., has just returned from a trip to the coast. He reports business as excellent.

SOUTHERN NOTES.

Mr. W. S. Atchison, the special agent at Atlanta, Ga., for the Short Electric Railway Co., has recently closed a contract for the first electric road to be operated in South Carolina, that of the Columbia Electric Street Railway Light & Power Co., Columbia, S. C. The electric equipment will consist of sixteen 20 h. p. single-reduction motors, and two 133 h. p. multipolar generators, with five miles of line construction, all of the Short system. Water power will be used, furnished by Victor turbines.

Mr. William Oswald, general manager of the Southern Electrical Manufacturing & Supply Company, Limited, of New Orleans, La. has closed contract with the Camperdown Central Refinery, of Baldwin, La., for 220 incandescent lights, with engine. His company have just completed the central station plant for 1,600 incandescent lights at Algiers, La. The station is equipped with four Edison dynamos and two New York Safety engines, and is one of the finest plants in the South.

PHILADELPHIA NOTES.

Merchant & Co. have stopped entirely the importation of their three grades of "guaranteed roofing plates," and are now manufacturing the plates at their works, 2025 Washington avenue, Philadelphia. Cards of admission, not transferable, can be obtained to these works upon request. The concern state that they are securing much better results from the domestic manufacture than they ever obtained with the imported.

The Partrick & Carter Co. are meeting with remarkable success with their new automatic set-back annunciator, the cost of which is a very little over that of their regular style annunciator.

Messrs. W. H. Weston & Co. are running night and day filling orders for switches and switchboards. They are just completing a large switchboard for F. P. Little & Co., of Buffalo.

THE INTERIOR CONDUIT SYSTEM IN SAN FRANCISCO.

The Edison General Electric Company, of San Francisco, has just completed in the new Mills Building, of that city, one of the most complete conduit systems installed in this country.

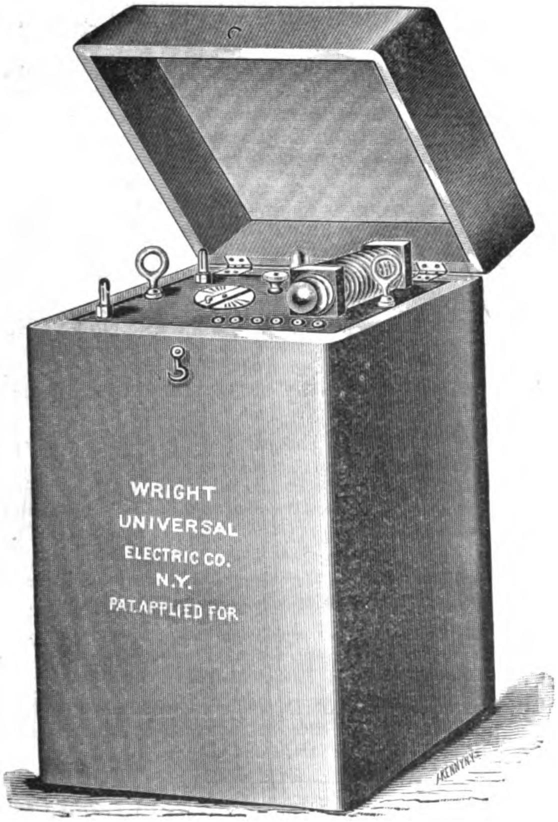
The Mills Building, situated on the corner of Montgomery and Bush streets, is thoroughly fireproof, and is constructed of yellow brick; it has ten stories in the main building, with an addition on the roof. The method of conduiting this building has, perhaps, been different from methods heretofore employed.

The architects, Messrs. Burnham & Root, of Chicago, bore in mind that a conduit system was to be employed and made provisions for the reception of the same as they would for gas or water systems. The system employed is practically as follows: The main feeders all rise in a pipe shaft, each floor being fed by a separate feeder, there being in all some 24 tubes, including motor circuits. The hall mains are all fed from a cut-out box located in a toilet closet by the shaft. These mains are run around the corridor on either side, and are conveniently located behind an oak cornice, which corresponds with the general finish of the building. Cut-outs are intersected in these mains, one in front of each office or room, and are concealed behind a door in the cornice. From this cut-out the office circuit is fed. The branch circuits are one-half inch conduit coupled and telescoped within a three-quarter inch tube, and are run above the tiling of the office they feed. Each office circuit is controlled by a switch conveniently located in the oak finish by the door. The hall circuits are also fed from the corridors, and are upon a separate system. They are also double tubes and are protected from acids and alkalies which might percolate through the cement upon which the marble flooring is laid by having the ashes and earth used for deadening removed from around the tube which is then raised by small pieces of tubing laid crosswise beneath it so as to leave a space entirely around the conduit. This is then filled in with plaster of paris, which forms a cheap and ample protection.

The conduit employed is that of the Interior Conduit and Insulation Company, of New York. The system was installed under the supervision of a representative of that company, Mr. Paul Oscanyan, who has spent five months on the work in San Francisco.

THE WRIGHT COMBINATION PRIMARY BATTERY.

This battery shown in the accompanying illustration consists of a three-compartment glass jar, and is a single-fluid battery with no odor, no creeping of salts and is hermetically sealed. The little outfit is most compact and complete, in a handsome polished oak case, and has a weight of only five pounds. It has an E. M. F. of six volts giving from six to ten amperes. The raising of a little nickel-plated knob puts the battery in action, and upon simply pushing a button, the contact is broken, and the elements are removed from the solution. A coil is placed on the top of the cell and inside the cover, (as usual). On this cover is a small switch with contact steps so arranged as to give galvanic, faradic or cautery currents as desired, as well as a suitable current for lighting the miniature lamps now so commonly used by physicians and dentists. This battery is placed on the market by the Wright Universal Electric Co. The battery is charged with a solution of their "electric sand" and pure water, no acid, whatever, being used. The cost of this charge is claimed to not exceed two cents.

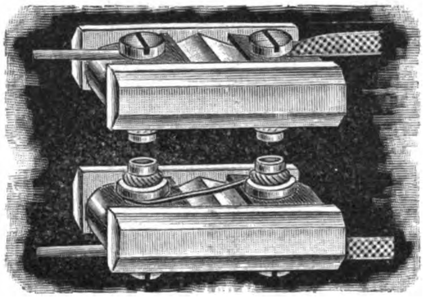


Wright Combination Primary Battery.

This battery and a number of other interesting novelties, among which is an ingenious electric headlight for bicyclists, will be exhibited at the American Institute Fair, which opens on the 10th of October.

NEW "LIGHTNING BUG" FIXTURE CUT-OUT.

The accompanying illustrations show a new fixture cut-out, the invention of Mr. Duane N. Gleason, of the E. P. Gleason Manufacturing Company, who are making and introducing it. This fitting is called the "lightning bug" cut-out to distinguish it from the several other fixture cut-outs made by the same firm.



Figs. 1 and 2.—"Lightning Bug" Fixture Cut-Out.

The "lightning bug" possesses some unique features; for instance, the leading in and out wires are secured under the flat screw heads, as shown in Fig. 1. These screws are inserted into and pass through brass strips on each end of the cut-out; the strips, being bent into U shape, the screw enters it near each edge and serves to keep the brass in position on the porcelain block.

On the reverse side of the cut-out, Fig. 2, will be seen the fuse wire, secured by washer and nut to each of the terminals of the leading in and out wires, the fuse wire being inserted independently and without disturbing either of the main wires. This feature is very important, as many know who have tried to fuse an old style cut-out in which the fuse and main wires are loosened when one of the terminal screws is slackened up. In the "lightning bug," the main wires need never be disturbed at their terminals for fusing after once being put in position.

The "lightning bug" is making many friends, and the Gleason Company are daily receiving orders from those who have seen a sample.

THE SCHUCKERT ELECTRIC PROJECTORS.

The display in connection with the Columbus Celebration to be held in Chicago on Oct. 11, 12 and 13 will include the operation of two parabolic search lights made by Schuckert & Co., of Nuremberg, Germany. These search lights will have an illuminating and penetrating power claimed to exceed any projectors ever employed in this country, being of the same type as the Schuckert search lights now in use in nearly all the navies and armies of the great European powers. Messrs. Schuckert & Co. have appointed Mr. Fred. W. Tischendörfer their representative at the World's Columbian Exposition.

THE GENETT AIR BRAKE FOR ELECTRIC CARS.

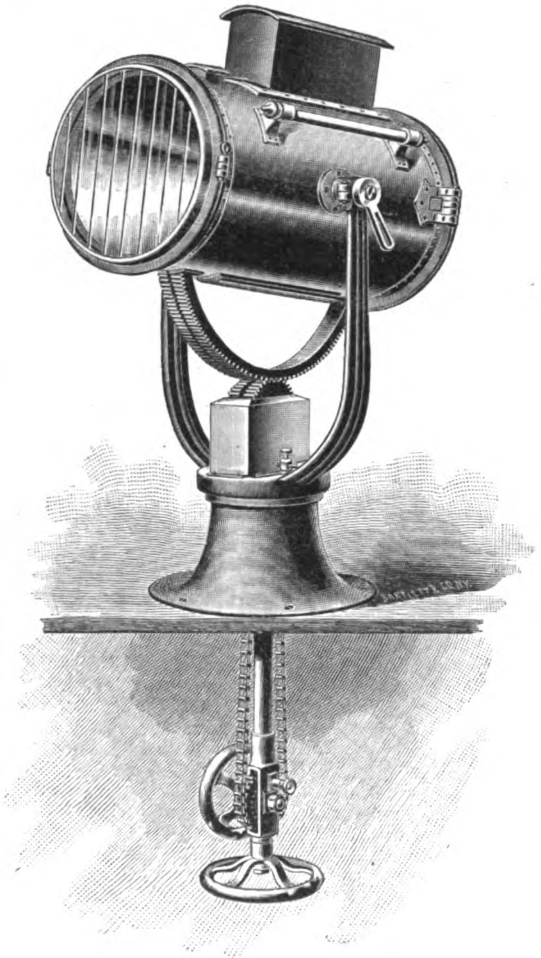
The necessity of a means of stopping electric motor cars instantly has long been perceived, being, indeed, one of the chief means through which a car can be run at full speed as long as possible, so as to get real rapid transit. A device recently introduced to this end is the Genett air brake, manufactured by the Genett Air Brake Co., of 150 Broadway, New York, and 11–23 South Jefferson street, Chicago. This brake is of simple construction but is very powerful, and is easily operated. It has already been placed upon roads in this city, Buffalo, Paterson, Denver, etc., and most satisfactory reports are being made upon it.

THE WARD ARC LAMP.

The Electric Construction and Supply Co. of 18 Corllandt street, this city, have issued a handsome catalogue descriptive of the well-known Ward arc lamp and containing, besides, an interesting introduction on the evolution of electric lighting, and several pages of testimonials from well-known people in all parts of the country. The catalogue is beautifully printed by Bartlett & Co., and is illustrated by some remarkably fine wood cuts executed by the same firm.

The contents include excellent descriptions of the Ward arc lamp in its various forms, single, double, short, etc., both plain and ornamented in a number of attractive styles; street railway and alternating current lamps; special lamps for photo-engraving and focusing work, and for theatrical, stereopticon and ophthalmoscopic uses; and also of the search lights recently introduced by this company with so much success.

In this department as in every other, there is room for development, and the Electric Construction and Supply Co. have devised a special form of small search light, shown in the accompanying illustration. Such a light must not only possess sufficient candle power, with facility of concentration and penetration, but must present an attractive appearance, in keeping with the trim and finish of the craft upon which it is installed. It must also be easy to manipulate and hard to derange. A great many owners of small craft, especially pleasure steam yachts, want a small machine and apparatus, but they like to get out of it a light of candle power commensurate with many times their tonnage. The small "Ward" search light is not equal to the powerful projector of a large man-of-war, but it will be found far beyond expectation, giving a strong beam of immense range. This light works automatically. It is placed on top of the cylinder so that only the carbons with their rods pass into the cylinder. The condenser used is a concave ground glass lens, silvered on the convex side, with about 18 inch focus. This form of lens yields the greatest amount of light with a given current. The glass lens never tarnishes, and therefore needs no cleaning, yet always affords the same amount of light. The lamp and appurtenances are made entirely of finished brass It is so constructed as to be controlled from within the pilot house by means of the shaft as shown in the engraving. If need be, the fixtures can be removed and the light operated by handles on the cylinder. The larger search lights can be fitted with a lens similar to that used in the small search light.



New Ward Search Lamp.

PHILADELPHIA NOTES.

The Harrisburg Foundry and Machine Works has just taken orders for engines, boilers, etc., as follows: Steelton Electric Light & Power Co., two 150 h. p. Ideal engines, boilers, pumps, heater, etc., Wilkesbarre & Wyoming Valley Traction Co., two 250 h. p. Ideal tandem compound engines, boilers, pump, heater and everything comprising a complete steam power plant, Lalande & Grosjean Manufacturing Co., Harrisburg. two large smokestacks, several large filters from the New York Filter Co., and a lot of ammonia stills and retorts from the Harrisburg Pipe Bending Co.; The McFarland Printing Co., Harrisburg, a large tandem compound engine; the Chillicothe (O.) Electric Light & Power Co. a 150 h. p. tandem compound engine. In addition to this they have just received orders for a number of simple and compound engines of various sizes which they are building for delivery to their New York house to be used in plants which are in process of construction.

The Pennsylvania Electric Engineering Co. has contracted to furnish the Steelton Electric Light & Power Co. of Steelton, Pa., with two 1,000-light 2,000-volt National alternating self-contained generators, two 150 h. p. Ideal engines, three 100 h. p. return tubular boilers, steam pumps, friction clutches, etc., and are to erect two miles of pole construction. This is a new plant and will be started within 60 days. An arc machine will be added to this plant in the spring.

The Commonwealth Electric Co. has closed a contract with the Geo. Manz Brewing Co., 6th and Clearfield streets, for a 125-light plant complete, a 100-light plant for Mr. Roland Smith, and a Howard watchman's clock for the Philapelphia Watch Case Co. The Commonwealth Co. make a specialty of repairing converters and rewinding armatures and fields. They keep several experienced men on this work alone.

WESTERN NOTES.

The Elkhart Converter is said to be making a splendid record for itself all over the Western country. The Electric Appliance Company who are taking care of the Western trade report receiving a number of very large orders, and in fact the demand has been so heavy as to exhaust their stock, and make it necessary for the factory to run night and day.

Taylor, Goodhue & Ames, the new Chicago electrical supply dealers, have been appointed general selling agents for the Columbia incandescent lamps manufactured by the Columbia Incandescent Lamp Co., of St. Louis. They are already booking some nice orders, and business is coming in in a way that exceeds all their expectations.

Mr. Jean A. Wetmore, of the Okonite Co., was among the well-known electrical visitors in Chicago last week. Mr. Wetmore, as an exponent of the advantages of using Okonite, is known from Maine to California, and his persuasive eloquence is something not to be forgotten.

The Sebastian Lathe Co., of Cincinnati, Ohio, have been driven by increase of business to remove to a large three-story factory building on Culvert and Harrison streets, where, with increased facilities, they will be able to meet every demand for their admirable tools promptly.

Washington Carbons.—The sales of Washington carbons by the Central Electric Company, who are Western agents, during the past week have been very large, and the Central can be congratulated upon carrying the goods in stock and giving their customers ready shipments.

Mr. Horatio S. Conner has been appointed superintendent of the Consolidated Electric Lighting Companies of Minneapolis. Mr. Conner will have charge of all three of their stations.

Mr. Frank B. Rae, the well-known electrical engineer of Detroit, was visiting in Chicago for a few days and was a caller at the Western office of **The Electrical Engineer.**

E. A. Armstrong Co., of Detroit, are going to install 600 incandescent and a few arc lights on incandescent circuits in their new factory at Evergreen Park, near Chicago.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

THE
Electrical Engineer.

VOL. XIV. OCTOBER 12, 1892. No. 232.

THE ELECTRIC HOISTING PLANT OF THE DENVER PUBLIC WAREHOUSE

BY

Lewis Searing

PROBABLY the largest electric hoisting plant for warehouse purposes thus far installed is that of the Denver Public Warehouse Company, of Denver, Col. The progressive policy of the Warehouse Company led them at the outset to adopt electricity as the motive power for the building, but the local electric light company (of which there is but one), who were to furnish the current, soon showed them that it would not be profitable to any one but the electric light company. The Warehouse Company then had their engineer draw up plans and specifications for a complete steam plant, and various propositions from local isolated plants to furnish the required power were entertained. The electric light company, in the meantime, thought it over and finally made a proposition which assured the Warehouse Company of a reasonable return on their investment.

Power is supplied from the 3-wire motor circuit of the Denver Consolidated Electric Company, current for which is generated at their West Denver station, two miles distant, by two 80 K. W. 250-volt Edison generators, giving 500 volts at the switchboard of the warehouse. Charges for power are made on the meter basis, with a minimum rate, per 746 watts delivered at the warehouse, as measured by a Thomson wattmeter.

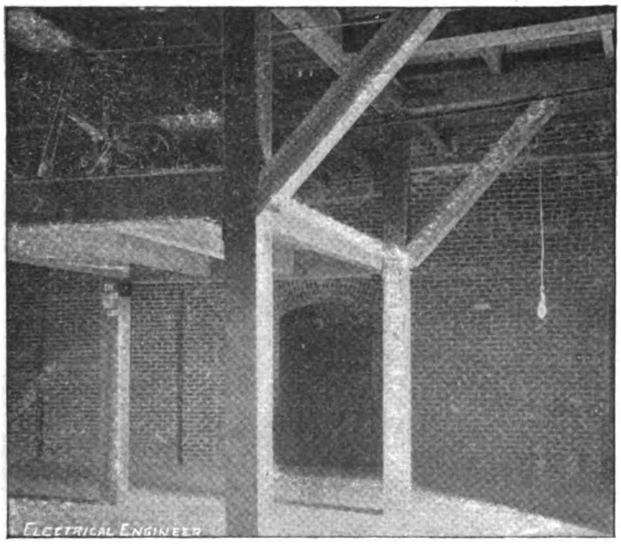


FIG. 1.—PLATFORM AND HOIST IN SECTION 2.

The plant is laid out for 10 hoists geared to six K. W. electric motors, and two freight elevators, operated by 15 K. W. motors. The present plant comprises four of the hoists and the two freight elevators, with switchboard and wiring complete for the full equipment.

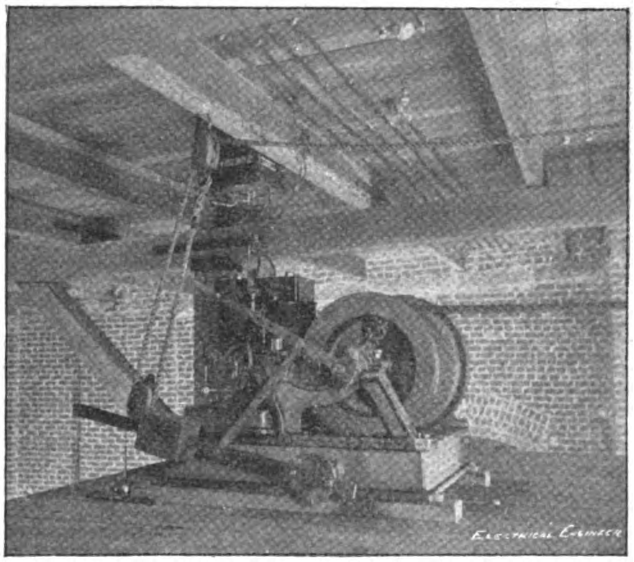

FIG. 2.—VIEW OF HOIST; SHOWING ARRANGEMENT OF TUBING.

The building, Fig. 5, is a substantial brick structure and measures 107 feet in width and 200 feet in length, with finished basement and four stories. The foundations are of solid masonry and the framing throughout is of the heaviest and most approved form of mill construction. The building is divided transversely into five sections 40 feet wide, by thick party walls, the only connection between the sections being through two openings in the party wall in each story, protected by fireproof doors. The warehouse is located at Nos. 50 to 70 Corbett street, a spur of the railroad approaching the rear.

The two elevators are so disposed as to admit of the speediest handling of heavy merchandise. Wide doors at the end of every section enable goods to be received into any portion of the building, either from the front or rear. The office occupies a portion of the first story of the first section, extending in length to the middle of the section and one-third of the section in width.

The architects of the building are Andrews, Jacques & Rantoul, of Boston, Chicago and Denver. The work was supervised by Mr. Clarence Gardner, their Denver representative. The entire scheme of the building indicates that it has been most successfully planned in regard to economy and facility of administration and also fire protection.

On the top floor of each of the five sections near both the front and rear doors, are erected platforms upon which stand the hoists. Fig. 1 shows the platform and hoist in the front end of section 2.

In the basement of the middle section and near the elevator shafts are located the motors and machines for operating the elevators. A wooden conduit of rectangular section, 24 inches wide and 1¾ inch deep is secured to the inside of the end wall of the building and extends from the rear end of the office to the upper part of the second floor where the conduit divides into two smaller conduits, 11 x 1¾ inches, running horizontally to the front and rear of the building, finally rising again and terminating under the roof at the points in line with the two rows of hoists. A similar conduit, 12 x 1¾ inches, extends from the office to the basement.

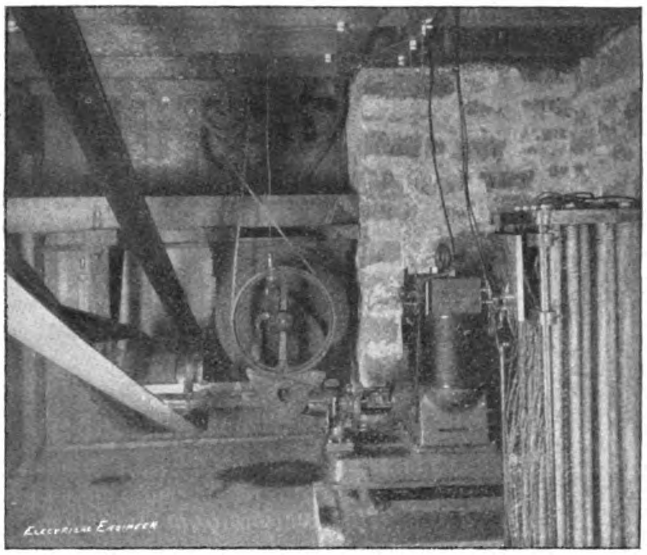

FIG. 3.—ELEVATOR MACHINERY IN THE BASEMENT.

In these channels are placed the insulating tubing of the Interior Conduit and Insulation Company, containing the necessary wires for ten motor circuits on the top floor and for two motor circuits in the basement. Twelve tubes and wires run to the top floor, two of which are used for the return. Three run to the basement, one of which is the return. Intersection boxes are placed at proper intervals in the tubing to facilitate the introduction or removal of wires, and terminal boxes are placed at the end of every circuit.

Emerging from the wooden conduit at the top floor the tubing runs along on the under side of the roof and is secured there by metal strips. Each tube terminates at its respective motor, except the return which leads by all, junction boxes being placed at each motor to admit of connection with the return. This arrangement of tubing is well shown in Fig. 2. The tubing in the basement is secured to the under side of the first floor and branches to the motors in a manner similar to that on the top floor.

Each motor is protected by a double-pole cut-out and a double-pole switch. Conveniently located near each motor are the starting rheostats, all of which are of the iron frame, non-combustible type. Those on the top floor have interposed between themselves and the roof a sheet of asbestos to prevent fire being communicated to the building should the rheostat become overheated.

The hoists, manufactured by W. A. Crooks & Co., of New York, are of the cone friction and band brake type, with winding drum 18 x 18 inches. The drum is mounted loosely upon a shaft carrying a friction cone, and is made to engage with the cone by a rapid pitch screw operated by a lever at the end of the shaft, which forces the drum along the shaft against the cone. The shaft is geared, by a double-reduction gearing, terminating in a raw-hide pinion, to the armature shaft of a standard 500-volt, compound wound Edison motor of 6 K. W., or 8.5 K. W. capacity, bolted to the base frame of the hoist,

The band brake is operated by a foot lever on the same side of the hoist as the lever operating the drum. The motors run continuously, the operations of hoisting and lowering being effected entirely by the hoist levers.

The hoisting rope used in this plant is 4½ inches circumference, four strand, "Stevedore" brand, manilla rope, with internal lubrication of plumbago; it is manufactured by C. W. Hunt & Co., of New York. The blocks, manufactured by the same firm, are of lignum vitæ wood, 16 inches in diameter, with steel roller bearings and are hung, not fixed, to the hoist beam, so that the block is always in line with the rope, reducing the wear on the rope to a minimum.

The hoists are arranged to be operated from any floor of a section by the simple pulling of a hand rope. The method of accomplishing this is shown in Figs. 1 and 2, and is as follows: The friction and brake levers are connected together by a link with an adjustable weight placed on the brake lever. A single hand rope, ¾ inch in diameter, of manilla, passes up through all the floors, leading over a pulley at the top floor to the hoist where it is connected through a system of blocks to the brake lever. The weight on the brake lever serves to keep a continuous tension on the brake band, which is sufficient to hold any load the motor is capable of lifting. When the operator pulls on the hand rope the weight is lifted, which releases the brake. The friction and brake lever being connected, this motion also moves the drum against the friction cone, but not enough to engage with the drum; the drum therefore unwinds from the weight of the load. A further movement of the hand rope, and consequently the levers, engages the friction wheel causing the motor to wind up the load. In the rapid handling of the hoist occurring in practice, the braking and hoisting is done entirely by the friction.

The 6 K. W. hoists are geared to handle a load of 500 lbs. at a speed of 300 feet per minute. They were tested to 850 lbs. The 8.5 K. W. hoists handle a load of 750 lbs. at the same speed and were tested to 1,200 lbs.

The freight elevators, two in number, are of the worm-geared belt factory type, manufactured by the Crane Elevator Co., of Chicago, having a capacity each of 5,000 lbs. at a speed of 50 feet per minute.

The question of space being one of considerable importance in a warehouse, the elevator machine was suspended from a frame-work of 8 x 8 inch timbers, to allow the traversing sheave to be placed entirely below the floor, thus confining all the elevator machinery to the basement, as shown in Fig. 3. Upon a foundation of concrete capped with Fort Collins stone, at the base of the elevator shaft, stands the 15 K. W., 500-volt compound Edison motor. The motor carries a pulley 9 inches in diameter with 10-inch face, which belts up to a 36 inch pulley on a countershaft overhead running 287 revolutions. A 29-

FIG. 4.—THE OFFICE AND SWITCH BOARD.

inch pulley on the other end of the counter-shaft belts back, by a straight and crossed belt, to the 14-inch pulleys of the elevator machine, running 325 revolutions per minute. This part of the plant has its exact duplicate at the other elevator shaft.

The elevator motors and counter-shafting are kept running continuously, the operation of the elevators being controlled entirely by the shipper motion on the elevator machines. Although a large amount of space could have been saved by the use of a motor coupled direct to the worm shaft of the elevator machine, this method was adopted as being the one which would give longer life to the motors, and do away entirely with sparking commutator and burnt rheostats.

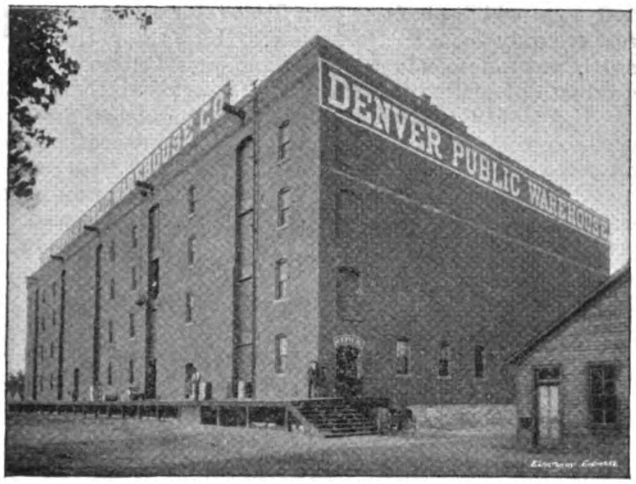

Fig. 5.—The Warehouse; Showing Hoist in Operation.

The switchboard, illustrated in Fig. 4 is located in the rear end of the office, is 5 feet high and 10 feet long, built up of three slate slabs, 1 inch thick and mounted in an iron frame of 1½ x 2 inch angle iron set out two feet from the wall. Each circuit is fed from the bus bars through a spring switch and an Edison ammeter. A double-pole "Ajax" switch at the centre of the board controls the whole system. The fuses for each circuit are on the back of the board. Completing the electrical equipment of the building are 104 incandescent lights supplied from the city circuit, a system of electric call bells throughout the building; and a watchman's clock and a special fire-alarm connected with the city fire department.

The officers of the company are: H. R Wolcott, president; C. G. Codman, vice-president; J. L. Jerome, secretary and treasurer; R. J. Freeland, superintendent. The power plant was designed and installed under the personal supervision of Messrs. Shepard and Searing, mechanical and electrical engineers, of Denver, Col.

THE PROTECTION OF METALLIC SURFACES.

By producing a thin layer of magnetic oxide of iron upon articles of wrought or cast iron, their surfaces may be preserved from atmospheric deterioration. This fact has been known for some time. Mons. P. H. Bertrand, however, has recently applied it as follows: He coats the surface of the iron or steel by electro-deposition with some metal or alloy which is capable of being volatilized at a temperature of 1,000° C. The article, or portion of machine, for example, is then introduced into a furnace heated to the required temperature. The iron becomes oxidized, but only to the magnetic oxide stage, and the metallic coating volatilizes, the operation being complete in a few minutes.

THE GENESIS OF THE MODERN DYNAMO: ANTONIO PACINOTTI.—IV.

(*Conclusion.*)

BY

Franklin Leonard Pope

In 1869, M. Zénobie Théophile Gramme, of Paris, a native of Belgium, by occupation a pattern-maker, designed and constructed the first of the magneto-electric machines with which his name has since become identified. His invention was patented in France,[1] in Great Britain,[2] and in the United States.[3] At a meeting of the Academy of Sciences, of Paris, on July 17, 1871, Gramme's machine was presented by M. Jules Jamin, and its performance elicited the warmest commendation from the members of that learned body. We give an extract, in translation, from the paper of M. Jamin read on this occasion, as published in the transactions of the Academy.[4]

Mr. Jamin, after calling attention to the well-known experiment of exciting an electric current in a closed helix by thrusting a bar magnet through it in the direction of its axis, said:

[TRANSLATION.]

This experiment leads to the idea that by making use of proper mechanical expedients it is possible to obtain an apparatus capable of furnishing continuous currents indefinitely.

Suppose that the electromagnet, instead of being a rectilinear bar, takes the form of a ring E E' E'' E'''. Place this ring under the simultaneous influence of the north and south poles of a horseshoe magnet N S, and suppose it to revolve about its own axis in the direction indicated by the arrows.

The south pole will produce in the adjacent part of the ring an electric current, the direction of which may be determined either by direct experiment or by theoretical considerations. It is apparent that the north pole produces in its neighborhood a current of opposite direction to the preceding one, and, also, that in the two parts of the ring at right angles to each other (which we may call *the lesser portions*) no current is produced. If, then, we wish to collect the two opposing currents produced simultaneously in the wire of the ring-magnet, we must place two corresponding collecting brushes at the lesser portions, which constitute the terminals of this new type of pile.

It is proper to give some details as to these brushes, which have been used heretofore, and are on the machine placed before the Academy. If the wire wound upon the ring is very thick, and if only a single layer of turns is placed upon the ring—a construction which will answer for some experiments—it is sufficient to bare the wires in a line and to establish brushes pressing upon the bared points. But if a greater length of wire is used, and if a greater number of layers are wound upon the ring, it is necessary to proceed as follows: Place a certain number of turns, three hundred, for example, in a series of separate windings upon the ring, then connect the wire to a piece of insulated brass, upon which the brushes press; then, without breaking the wire, continue to wind upon the ring three hundred more turns, forming a new series, attaching the end to a second piece of brass adjacent to the first, and so on. In this manner the wire wound upon the ring forms an endless conductor divided into a certain number of equal parts the junction points of which are soldered to insulated metallic pieces of a strength and shape to resist prolonged friction. These pieces of brass (commutator segments), placed

[3] No. 120057, of Oct. 17, 1871.

[4] *Comptes Rendus*, lxiii, 175 (1871).

like radii upon the side of the ring, are represented in the figure. The brushes, F, press upon several of them. It is easy to see that two magnets instead of one may act upon the same ring, that is to say, four magnetic poles, or even a greater number, may be used. It goes without saying that a brush is always necessary between each two successive poles, and consequently as many brushes are necessary as there are poles.

It is possible to substitute in place of the permanent (field) magnet electromagnets which are excited by part of the current from the machine itself, following the well-known method; at the beginning of the movement the residual magnetism induces a feeble current in the ring; part of the current serves to excite the field-magnets, and the machine soon reaches its full power.

The machine submitted to the Academy is of this kind; it has two electromagnets, and, consequently, four poles which act upon the ring. It has four brushes, two of which conduct half the current into the field magnets, while the other two furnish the external current. On each arm of the electromagnets are wound seven kilograms of copper wire three millimetres in diameter. The ring is fitted with 200 metres of wire, two millimetres in diameter, weighing about seven kilograms.

The machine is driven by a fly-wheel operated by a man. It is capable of decomposing the water in a voltameter, of heating red hot and fusing 25 centimetres of iron wire nine-tenths of a millimetre in diameter, while if the ring be turned slowly the needle of a galvanometer, coarsely made of a single turn of wire, may be made to deflect. These effects become the more noticeable as the speed of rotation increases, until the maximum speed corresponding to 700 or 800 turns a minute is reached, which is easily attainable if the machine be put in motion by a steam engine. The effects, moreover, differ according to the characteristics of the wire wound upon the ring; effects of quantity are produced with a short, thick wire; of tension with a long, thin wire.

In a word, by means of this machine may be obtained every effect obtainable with the voltaic pile. There is, therefore, reason to think that it may be substituted for the pile with advantage in many cases both in industrial applications or in scientific research.

Immediately after the publication of this account of the Gramme machine, Dr. Pacinotti addressed a note to the editor of *Comptes Rendus*, which appeared in that journal as follows :[5]

[TRANSLATION.]

ON AN ELECTROMAGNETIC MACHINE CONSTRUCTED IN 1860 UPON THE SAME PRINCIPLES AS M. GRAMME'S MACHINE.

[Extract from a letter of Mons. A. Pacinotti to the Perpetual Secretary.]

(Referred to the Department of Physics.)

PISA, 20th August, 1871.

I find in the *Compte Rendu* of the proceedings of July 17, 1871, a note by M. Gramme upon an electromagnetic machine for producing continuous currents, constructed upon the principle of the transverse electromagnet, which I employed in 1860 in the construction of an electromagnetic machine, and which I likewise used in producing a continuous induced current. I published at that time a note containing a description and even the drawings of my little machine, in Vol. xix of the journal *Nuovo Cimento*. I send you a copy of this note asking you to be kind enough to present it to the Academy in support of my claim.

I do not contend with M. Gramme for the merit of having discovered the principle of the transverse electromagnet, by placing about it more than two influencing poles, but I desired that it should be clearly stated that the revolving electromagnet, provided with a commutator within the influence of the poles of a fixed electromagnet, had been constructed by me as far back as 1860; it produced a continuous induced current, indicating by the galvanometer considerable strength while passing through a voltameter. My machine is still preserved in the Cabinet of Technological Physics at the University of Pisa.

The foregoing account of Pacinotti's researches has been gathered in considerable part from a memorial prepared by him for presentation to the jury of the Turin Exposition, which has been supplemented by many additional particulars of interest gathered from his own lips. In it we read again the story of one of the master minds of experimental science; we see the painstaking, intelligent young student of nature's mysteries. Theory leads to experiment; experiment suggests new theories; the ever-ready note-book is at hand for the recording of every result, however apparently insignificant or unimportant; and thus day by day a deeper insight is reached; a more comprehensive grasp of the subject is gained, and at length the coveted result is brought to pass. Such a mind is surely not unworthy to be accorded a place in the front rank of the experimental philosophers, investigators and discoverers who have made the history of electromagnetism so illustrious, and of which Faraday, Henry and Joule have been such distinguished examples.

Antonio Pacinotti was born in Pisa, Italy, in June, 1841, and hence, at the time of the commencement of his researches in electromagnetism was but seventeen years of age. He had not, in fact, completed his twentieth year when he constructed the machine which has been described and upon which his fame as a discoverer and inventor will rest securely for all future time. His father, Luigi Pacinotti, was a descendent of a prominent Italian family, a graduate of and subsequently Professor of Mathematics in the University of Pisa, and was a distinguished mathematician and physicist. The younger Pacinotti, at an early age, manifested an inherited predilection for mathematical and physical studies, in which he was greatly encouraged and assisted by his father. He served with credit as a volunteer in the Corps of Engineers in the Austrian war of 1859, after which he returned to Pisa and prepared himself for examination for entering the university, receiving his degree with honors in 1861. In May, 1862, he became Assistant Professor of Astronomy in the Royal Museum of Florence, where he continued until December, 1864, when he received the appointment of Professor of General and Applied Physics in the Royal Institute of Technology of Bologna. In March, 1873, he was appointed Professor of Physics in the University of Cagliara. At the Universal Exposition in Vienna, in 1873, he exhibited the little continuous current machine made by him in 1860, which had, meantime, been carefully preserved in the Physical Cabinet of the University of Pisa, and he here received the first formal acknowledgement of the scientific world of the merit of his discoveries in the shape of a Medal of Progress. At the Paris Electrical Exposition of 1881 Pacinotti again exhibited his machine of 1860, together with some later forms of application of the same principle which he had devised, for which he received from the jury of awards a diploma of honor.

Professor Luigi Pacinotti.

Mr. Hiram S. Maxim, the well-known American inventor, who visited the Paris Exhibition of 1881, made a careful examination of the machine exhibited by Pacinotti, and sums up his observations as follows :

Three machines are exhibited, one of which is the original machine of 1860, as shown in various publications. The second machine has substantially a Siemens armature, a Gramme commutator and field magnets resembling those in Farmer's old machine. The brushes are of wire, two on each side, and the machine in general seems to contain all the features of the Siemens machine of that date. The armature is of solid iron, cut like a pinion, its projecting teeth passing close to the poles of the field magnets. * * * The apparatus is mounted on a wooden frame and is driven by a hand wheel and belt. The third machine has its field magnets set in a position similar to those of the Wallace machine. On the sides of the armature are polar projections like those of the Brush machine. All the polar projections are enclosed in a square wooden frame, and are in form like those of the Heikel machine. The commutator is of iron, similar to Gramme's, and the winding of the armature appears to be annular and spiral, but cannot be clearly seen. The brushes are of fine wire curved inward, and have a box above them for containing water or oil. The field magnets are cylindrical in form.

The striking resemblance between the little machine of Pacinotti and the more recently invented machines of Gramme, excited much comment among visitors to the Exposition and led many a spectator to ask himself how it could have happened that the former had remained so long, as it were, completely forgotten. The explanation of this anomaly, however, is not far to seek. In the original memoir of Pacinotti the apparatus is described as having been primarily designed as an "electromagnetic machine" or engine. But the scientific world had at that epoch in the progress of the art, and very properly, reached the conclusion that until some new and economical source of electricity was rendered available, it was not worth while to pay much attention to the improvement of machinery intended to utilize electromagnetism as a motive power. As to Pacinotti himself, as our account of him shows, he was essentially an investigator and discoverer, and hence it may be conceded that it does not in the least detract from, but rather adds to the degree of credit due him, that he took no steps to patent or to promote the industrial utilization of his discovery with a view to his own advantage. In his cast of mind, as well as in his methods of investigation, Pacinotti strongly reminds one of Faraday, and it was no less a philosopher than Faraday who said: "I have rather been desirous of discovering new facts and new relations dependent on magneto-induction than of exalting the force of those already attained, being assured that the latter would find their full development hereafter."[6]

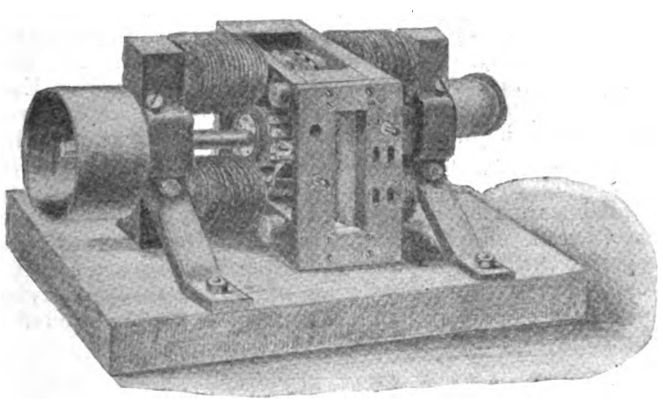
Pacinotti's Machine with Siemens Armature.

(From an original pencil Sketch by Mr. Hiram S. Maxim.)

Professor Pacinotti has been a not infrequent contributor to the scientific and technical periodicals of his native country. Perhaps the greater number of these miscellaneous papers relate to electrical investigations, but the sciences of astronomy, solar physics and mathematics have received more or less attention at his hands.



Pacinotti's Machine with Double Field Magnet.

(From an original pencil sketch by Mr. Hiram S. Maxim.)

For much of the hitherto unpublished material embodied in this article, the author takes pleasure in acknowledging his indebtedness to Mr. Charles A. Terry, of the Westinghouse Electric and Manufacturing Company, who visited Pisa in 1891, and obtained directly from Professor Pacinotti himself, and from other authentic sources, much valuable matter, which has been freely placed at my disposal. Of the two interesting photographic portraits of Professor Pacinotti, which have been reproduced, that published last week represents him at the age of twenty-three, when Assistant Professor of Astronomy in the Institute at Florence, while the one given on page 259 is from a negative made in Florence about ten years ago. We also give a reproduction of a portrait of his father, Professor Luigi Pacinotti, made in Pisa many years since. I also wish to acknowledge my indebtedness to Mr. C. O. Mailloux for his kindness in making an admirable translation of the original papers of Prof. Pacinotti referred to from time to time in this series of articles.

INSULATED ELECTRIC CONDUCTORS.[1]—XI.

BY

James Bowstead Williams MAE.

It is not to be supposed that the following articles can give exact directions for the manufacture of insulated electric conductors, such as would enable the amateur to produce insulated wires equal to the best now made and in use, for the successful manufacture of such wires requires the experience which only practice can give.[2] All the writer has aimed to do is to give a general idea of the processes and machinery used in the insulation of wires, thereby enabling the general reader to form an intelligent idea of this most important branch of electrical engineering.

Magnet Wires.—These wires are the simplest forms of insulated electric conductors, and consist of copper wire covered with cotton or silk fibre, the fibre being unsaturated with any insulating material. They are used in the construction of electromagnets, induction coils, armatures of dynamos, etc. They are made by winding one or more layers of the fibre, in the form of yarn, upon the wire by means of upright or horizontal winding machines. An ordinary upright winding machine consists essentially of a horizonal revolving platform upon which any suitable number of spools or bobbins containing the yarns are loosely mounted upon fixed, upright standards; means for drawing the wire perpendicularly through the centre of the platform; devices for regulating the tension and laying of the yarns; the whole being secured in a strong metallic framework provided with the necessary gearing, pulleys, etc. Such a machine will wind but one layer at a time. If more than one layer is desired they are best applied by means of a double or triple winder. In these machines the platforms, provided with bobbins, etc., revolve in opposite directions, thus causing the spirals of each layer to cross those of the layer immediately beneath it, and forming a more satisfactory covering for the wire than if the spirals of the different layers all had the same direction.

If the cotton and silk are perfectly clean and dry, the silk-covered wires will be better insulated than the cotton-covered; and, as the fibre of the silk is finer than that of the cotton and lies closer to the wire, more of the silk-covered wire can be wound in a given space.

While the silk-covered are more expensive than the cotton-covered wires, and better, still, for ordinary purposes, the latter will be found to be sufficient, provided that the cotton is perfectly clean and dry and is kept so. If the best results from the silk-covered wires are required, *white* silk should be used in preference to the green, for the dyeing material in the latter is nearly always detrimental to the highest insulation.

---

[6] *Experimental Researches*, ii, 168.

[1] *Copyrighted* 1892, *by J. B. Williams.*

[2] The consideration of insulating material proper will be discontinued for the present, and the manufacture of insulated electric conductors at once entered into; but items of importance relating to insulating material will be inserted whenever necessary.—Eds. E. E.

Magnet wire, as such, should only be used to convey weak currents. Its special use is in cases where induction should be kept as low as possible, as in the coils of reflecting galvanometers. In cases where it is not advisable to saturate the fibrous covering after the wires have been placed in position, as in galvanometer coils, the fibre should, if possible, be thoroughly dried and then protected by some form of moisture-proof covering. Silk, cotton, and other vegetable fibres are very hygroscopic, and absorb moisture quite rapidly if, after having been dried, they are exposed to a damp atmosphere. The writer has conducted many experiments upon fibrous-covered wires, especially cotton-covered, and found that this material absorbs moisture in less than ten minutes when thus treated. When cotton is dry and free from gummy and other foreign matters its specific resistance is high; and it continues to have this high resistance as long as it is *kept* dry. But just as soon as the fibre begins to absorb moisture this high resistance begins to decrease, and continues to decrease as the absorption progresses. A damp fibrous covering is but little better than no insulation at all.

The saturation of the fibrous covering of electric wires will be considered later.

Painted Wires.—These consist of electric conductors covered with fibrous material, usually cotton, saturated with paint. Fireproof and weatherproof wires belong to this class. Such wires are used mainly to convey strong currents, particularly those for the transmission of power and electric lighting. They are made either by forming two or more braids of the fibrous material upon the wire and then soaking the braids with paint, or by soaking the threads or yarns in paint as the braid is formed by a braider. A braider, a cut of which is shown in Fig. 1, resembles the upright form of winder in its general appearance, but in this machine there is no revolving platform to carry the bobbins around the wire. The bobbins are loosely mounted on upright standards, each of which is provided with an elliptical base, on the under side of which is a projection. The stationary platform of the braider has continuous and communicating slots, resembling the figure 8, formed in it in which the projections move. By means of specials gears under the platform these projections are caused to move around the wire which passes through the centre of the platform, but in a serpentine course. One-half of the bobbins pass around the wire in one direction and the other half in an opposite direction; and owing to the peculiar motion of the bobbins each thread is caused to pass alternately over and under the adjacent threads, thus forming a braid at the intersection of the threads. Each braider is provided with mechanism for drawing the wire upwards as the braid is formed upon it, and for operating the machine by hand while threading it; also devices for regulating the tension of the threads, and for instantly throwing the machinery out of gear upon the breakage of the thread. Each bobbin may carry from one to three separate threads. Double and triple braiders are used for forming a covering consisting of two or three overlying braids at one operation. A view of a double braider is shown in Fig. 2.

INCORPORATION.

The Nassau Electrical Manufacturing Company has filed articles of incorporation with the county clerk at Elizabeth. The incorporators are Andros B. Stone and Philip Hathaway of New York City, William D. Marvel of Flushing, L. I., and M. S. Rosenweig of Springfield, N. J. The capital of the company is $70,000, and its plant will be in Springfield, with the main office in New York.

SELECTORS FOR ELECTRIC CIRCUITS.

BY

Henry E. Vineing

SELECTORS are electrical instruments connected in series in a circuit, each instrument being arranged so that it responds to a certain combination of electrical impulses, such combinations of impulses being imparted to the circuit either mechanically or automatically at one point on the circuit. This enables an operator at one point to perform work indirectly at distant points. All that is required of the selector is that, after responding to its prearranged combination of impulses it closes a local circuit or circuits at the point at which such selector is placed. When the selector has done this it is possible by the intervention of electro-mechanical devices to perform a variety of work, such as ringing a call bell, turning a switch to start or stop electric lights, machinery, motors, etc., or even operate the valve of a steam engine or pump. Up to the present time the instruments invented for this purpose, as a rule, have been complicated and expensive. And on account of the principle on which nearly all have been constructed mechanically, have met with limited success in practical operation.

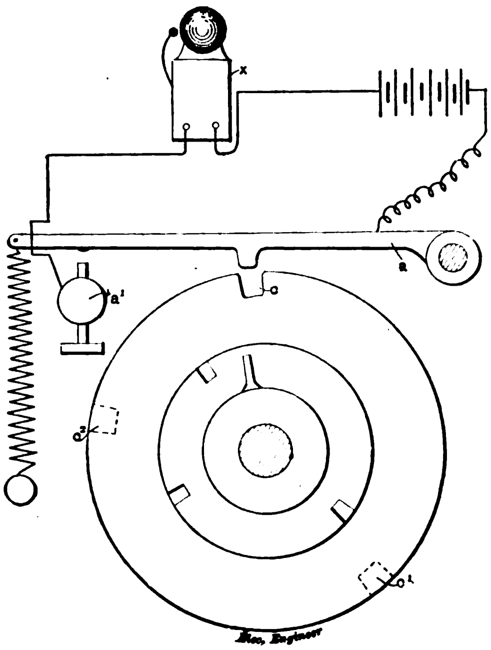

FIG. 1.—THE VINEING SELECTOR.

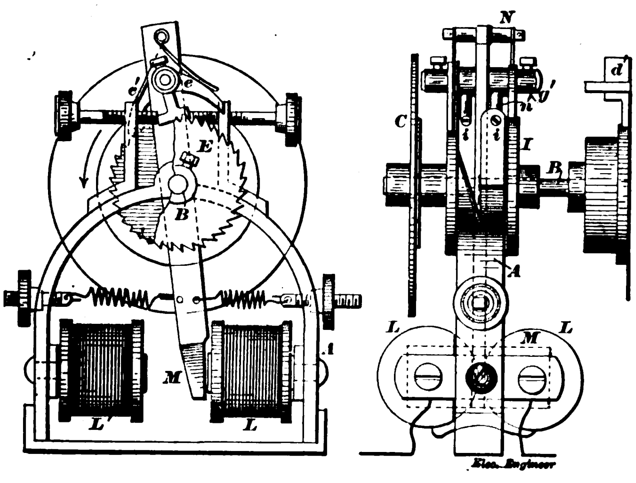

FIGS. 2 AND 3.—THE VINEING SELECTOR.

After studying the subject for some time I designed a selecting instrument which is a radical departure from previous methods and which is here described for the benefit of inventors who are grappling with the subject at the present time and also for the information of those interested in electrical development.

It occurred to me that the principle of an ordinary combination or safe lock which is operated, as all know, by a graduated dial rotated to certain positions to the right or left, could be applied. Thus by bringing the slots c, c^1, c^2, Fig. 1, in the discs or tumblers enclosed in the case, into such a position that the bolt, being impelled by a spring, drops into them the door can be opened.

Referring to Fig. 1, A represents a lock with three discs which are shown in position when the lock is closed, B, representing the same when open. To adapt the lock to the purpose required, contact arms a, a^1, are arranged, as shown. To these are connected the pawls, e, e^1, Figs. 2 and 3, which are attached to the upper end of the armature M, and which engage the ratchet wheels E, respectively. The shaft B being connected to the dial of the lock enables us to rotate the dial to any position either to the right or left and make any combination desired. A number of these instruments being connected up in series as in Fig. 4, with transmitting key A in circuit, I set all the instruments at zero. By sending impulses on the line I operate all the instruments, and, all being synchronous, all the dials are moved exactly alike and will be in the same relative position.

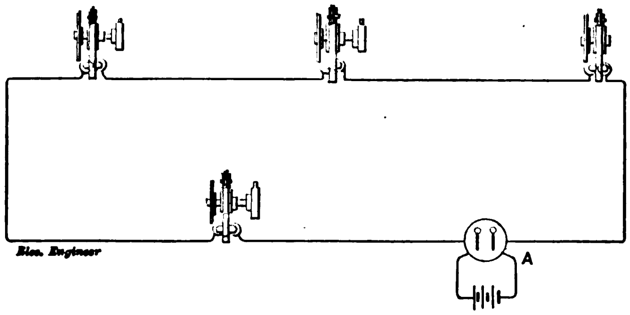

FIG. 4.—THE VINEING SELECTOR.

It is easily seen, therefore, that to operate any instrument, all that is necessary is to transmit impulses which will bring the dials to such positions as before described so as to make the combination of the lock required. Each lock being of a different combination that lock only will work, or circuit arms e e^1, Fig. 1, will be brought together only on the lock whose combination responds to the impulses given on the transmitting device.

The apparatus described is simple, cheap, and as infallible as a safe lock.

A NEW CURRENT REGULATOR.

MR. GUSTAV CONZ, of Hamburg, has devised a maximum-current regulator. Its object is to prevent an increase of current over a certain maximum pressure—not as an ordinary lead fuse which completely breaks the circuit, but it renders possible the further passage of the current by the insertion of a resistance. It is proposed to use this device with batteries of accumulators, and in place of electricity meters in house installations.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 203 *Broadway, New York City.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XIV. NEW YORK, OCTOBER 12, 1892. No. 232.

The man who makes a real discovery and works it out is a benefactor who ought to be rewarded.—John T. Sprague.

WHAT IS THE EDISON LAMP DECISION WORTH?

OUR readers will by this time have read the extra number of THE ELECTRICAL ENGINEER issued last week containing the official text of the decision of the U. S. Circuit Court of Appeals upholding the Edison incandescent lamp patent. They are therefore familiar with the status of affairs, so far as the Courts are concerned, and to the extent of their knowledge of the questions involved. We believe that in the main they will agree with us in saying that it is genuine cause for congratulation that another patent has been sustained. The amount of capital invested in electricity, unprotected by patents, has hitherto been so small that it may be laid down as an axiom that every time an electrical patent is sustained the whole industry benefits in the eyes of the public. In this case, moreover, there is again a vindication of the claims to inventive genius of a man whom no detraction can belittle. Mr. Edison has made fatal mistakes. His blind and dogged opposition to the alternating current has been an extraordinary exhibition of insensibility to the signs and progress of the times. Yet, after all the criticism that can be brought to bear upon him, he remains a great and noble figure in the inventive field—the father of incandescent lighting—a Columbus of modern electricity.

But what shall we say of the commercial aspects of the decision? The situation is, indeed, strangely complex. This very decision, rendered last week, inures apparently to the benefit of those who, but a few months ago, were just as much infringers as those whom they may now, perhaps, feel disposed to crush out of existence. Nay, more, the present management of the General Co. includes the wonderful organizing powers that created hundreds of sub companies, nearly all of which, under their incentive, have violated this patent, while it was still in doubt, from the earliest days of their incorporation. In many cases, these sub-companies operate incandescent lamps to-day in territory where, under this patent, local Edison companies enjoy, and are in the temper to enforce, exclusive rights. How is such a situation to be harmonized, if the decision is to be upheld? Are these sub-companies to be deprived of lamps by the very hands that sold them generators on which to run the lamps? It seems hardly credible.

That this decision gives the General Electric Co. power to close up all outside factories that make the ordinary lamp of every day use, seems to us indubitable. The decision is plain, broad, unequivocal. It is a decision that no shrewd or honorable manufacturer would care to defy. But, as we have pointed out before, the protracted delay in bringing the lamp cases to final issue has been an adequate excuse for many to begin lamp making, and the courts have said this in so many words. One obvious conclusion, then, is that in a great many cases the present lamp factories are likely to continue under some arrangement, the terms being special, perhaps, in each case. There is unquestionably need for more lamp factories than one, if only to meet the local demands of various centres of consumption. But whatever arrangement is entered into, it seems to us that it will and must respect the exclusive rights of the Edison licensee local companies, which, again, outside their own territory, have nothing to say.

But the question arises whether we are to assume that the Edison incandescent lamp is the only possible commercial one at this stage of the art. It is an open secret that the Westinghouse Company has a lamp made with a stopper instead of an integral glass globe, and the lamp is reported to be highly efficient. Moreover, many of us have seen Mr. Tesla's brilliant experiments with his single-rod lamps and with lamps entirely free from filaments—"illuminated vacuums" merely. Such a decision as this, even in view of the short time that the patent has to run, is an immense stimulus to invention. We do not see, therefore, any narrowing of the field or of opportunity.

THE NEW WESTINGHOUSE LAMP.

OUR advertising pages contain a most important announcement from the Westinghouse Company, as to their new lamp referred to above. The points as set forth in the circular are: That the new lamp requires no platinum; that it is made in separable parts, so that the incandescent burner can be renewed and the bulb and other parts of the lamp used over and over; that by means of "an important discovery the burner is rendered stable, its efficiency increased, its life prolonged, and its normal candle power maintained;" that, as the lamp will be made almost entirely by machinery, the cost will be reduced and there will be a saving of from 30 to 50 per cent. on the expense to consumers for incandescent lamps for a given service, and that neither the Edison patents nor those of any other company will be infringed. The manufacture of the new lamp has been begun at the Westinghouse factory in Pittsburgh, and the circular says that the lamps will be delivered in quantities after Dec. 1. We understand that the patent protecting this lamp is an old Sawyer-Man patent.

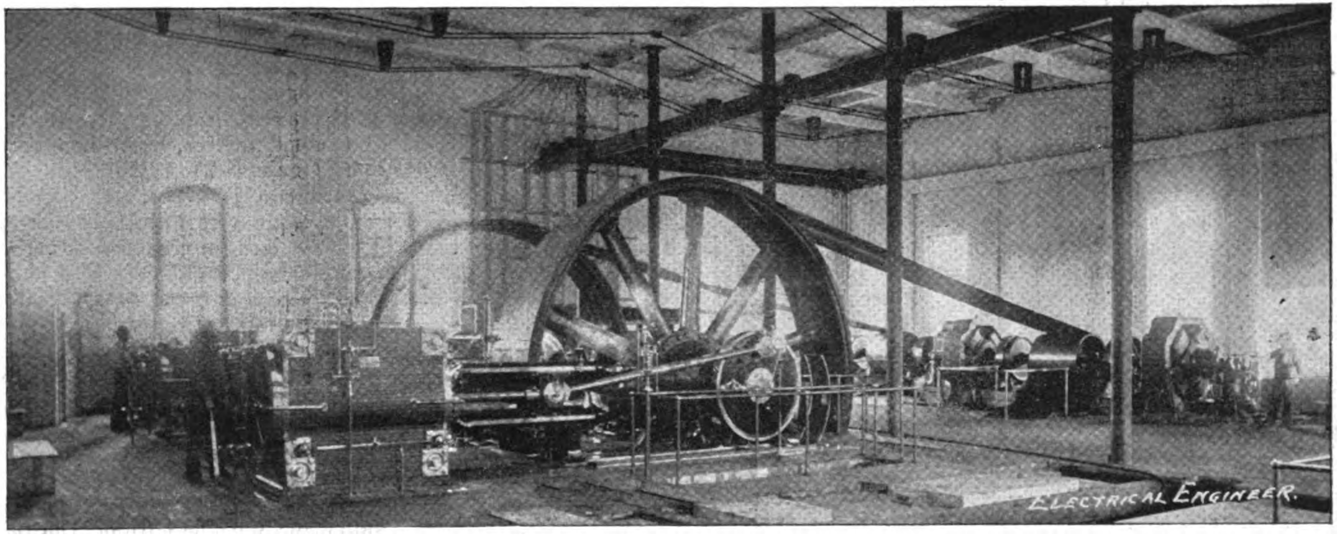
ELECTRIC RAILWAY DEPARTMENT.

THE NEW STATION OF THE LOWELL AND SUBURBAN STREET RAILWAY COMPANY, LOWELL, MASS.

BY

A. C. Shaw.

The history of the development of electrical railroading is one always full of interest to the engineer, and the different methods adopted by different engineers, must at all times serve as object lessons to those who are still contemplating changes. In The Electrical Engineer of October 21, 1891, it was my good fortune to be able to present to our readers a complete descriptive article—some 20 pages in length—on the power house of the West End Street Railway Company, of Boston, where the engineers who designedthe plant, considered that a moderately high rate of engine speed and counter-shafting was necessary. Recently in the Engineer of August 10, a description of the new Boston Edison Station was given, where direct-coupled engines were used in a totally different type of station. Now it is my intention to describe the new station of the Lowell and Suburban Street Railway Company, of Lowell, Mass., where Corliss engines of moderately large capacity are *belted* direct to two generators driven by the same pulley and on the same shaft, making a 500 h. p. unit of one engine and two generators each of 200 kilowatts capacity.



The New Station of the Lowell and Suburban Street Railway Company, Lowell, Mass.

The history of the company, like most other roads, is one of gradual development, and a few details may be found interesting. The Lowell Horse Railroad was organized in April, 1863, with an authorized capital of $100,000 and a paid-up capital of $40,128, and enjoyed a monopoly of the carrying business till 1886, when the Lowell and Dracut Company was organized with a capital of $15,000, and operated at first the line on Lakeview avenue, later entering the city on Bridge street. In 1887 the company was chartered with a capital of $100,000, and later increased the capital stock to $200,000. In 1889 $100,000 bonds were issued for the purpose of making an electrical equipment for the line built to Lakeview, a very beautiful and popular summer resort about five miles from Lowell. In 1890 the Lowell and Dracut Company, and the Lowell Horse Railroad were each operating about 13½ miles of track, and on October 20, 1887, the directors of the Lowell and Dracut Company obtained a controlling interest in the Lowell Company. In June, 1891, a consolidation of the company was consummated and a new company organized bearing the present title, the capital stock being placed at $300,000. At that time electric power was hired from the Lowell Electric Light Company, but soon after the consolidation it was decided to use electricity exclusively, and the right to issue $1,000,000 of bonds was secured for the purpose of building the station to be described, and for the general electric equipment of the whole road. The general plans were placed in the hands Mr. William D. MacQuesten, of New York, the details of the work being afterwards faithfully carried out by Mr. George B. Damon. It was early decided to use condensing engines, and as the company owned ground on the banks of the Merrimac River, a location about one mile from the centre of the city was at last decided upon, and ground broken on October 5, 1891, the power being started on July 23 of the following year. The situation of the new power house was well and carefully chosen, there being ample condensing water, splendid coaling facilities, the Boston and Maine Railroad passing within a few feet of the boiler-room, and ample room for increase. When the vast system of contemplated increase is completed, the station will also be electrically central, and though at present there has been a considerable extra expenditure in wire, yet in a few years it will be situated in the most economical centre of operation.

THE BUILDING.

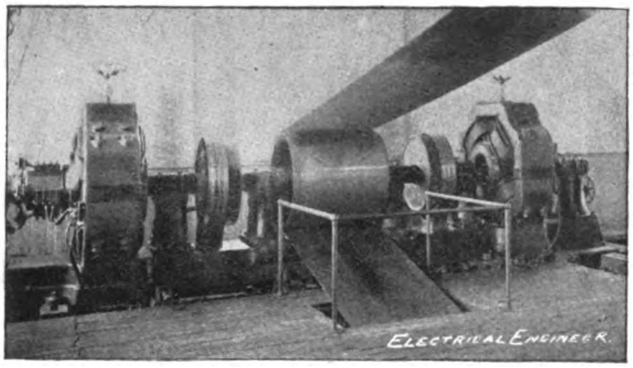
The building, a general plan of which is shown on page 347 measures 180 feet long by 125 feet wide, and is built of brick. The foundation walls, which are of granite, rest on a natural bed of clay and sand, on the average level of the Merrimac River, no concrete foundation nor piling being necessary. The bed stones are 5 feet wide and 18 inches thick, and on these rest the granite walls 3 feet thick at the bottom, tapering to 2 feet thick at the top, 13 feet above the clay. On top of the granite are the brick walls 16 inches thick with 4 inch pilasters on each side 10 feet apart, the roof girders all resting on top of the pilasters.

THE COAL STORAGE.

Next to the railway is the coal storage, shown both in the plan and elevation, which consists of a large room measuring 125 feet by 40 feet by 35 feet high from the concrete floor, and having a wooden bow-string girder roof. Furthest from the boiler-room side of this room, there has been erected a standard Boston and Maine Railroad trestle 8 feet above the level of the main track outside, and 18 feet above the concrete floor below, connecting with the Boston and Maine tracks at one end and extending about 70 feet beyond the coal storage room in the other direction. This room will have a storage capacity of 3,000 tons of coal, and communicates with the boiler-room, by means of two openings in each of which are provided Standard Fairbanks scales for weighing the coal consumed.

THE BOILER-ROOM.

The boiler-room measures 125 by 45 feet, by 42 feet high, and has a wooden monitor roof, with windows and ventilators, supported by bow-string girders. At present six return tubular boilers with overhanging front, have been installed, built by Messrs. Scannell & Wholley, of Lowell. Each boiler is of 250 nominal h. p. capacity, has a heating surface of 1,737 square feet with a grate area of 38 square feet, is 6 feet in diameter, 17 feet 6 inches long over all, and is fitted with 140 3-inch tubes 16 feet long. The boilers have a plain setting, and have a double wall, with a 2½-inch air space between the walls, and are intended to work at a pressure of 125 pounds. A wrought iron uptake conveys the smoke to the chimney and measures at the largest point 9 feet 5 inches by 3 feet 10 inches. In the boiler-room are situated two Deane steam pumps each large enough to supply all 12 boilers, the capacity of the boiler-room, with water.



THOMSON-HOUSTON DYNAMOS IN THE LOWELL STATION.

THE CHIMNEY.

The chimney rests on a pile foundation, 300 piles 25 feet long having been driven at 18-inch centres, on top of which is a granite foundation 10 feet high laid in Portland cement. The chimney is 195 feet high, is of circular section, and has two distinct walls all the way to the top. The outside wall is 20 feet 3 inches outside diameter at the bottom, and is 32 inches thick, tapering by 4-inch offsets every 35 feet, to 12 inches at the top where it has a diameter of 14 feet 6 inches, except at the cap where it is 17 feet 6 inches diameter. The inside shell is 9 feet 7 inches internal diameter and continues this diameter to the extreme top, the thickness of the shell being 20 inches at the bottom, tapering by offsets to 8 inches at the top. On top of the chimney is a cast iron cap, made in 10 sections, bolted together inside, and filled in with brick making a perfectly smooth appearance on the outside. The capacity of the chimney is 3,000 h. p., there being two boilers to each engine, and a spare set in case of accident.

STEAM PIPE.

From each boiler runs a 6-inch wrought iron steam pipe making a vertical bend and connecting with a horizontal wrought iron steam drum of 20-inch diameter, which is supported close to the wall, and runs across all six boilers. This drum is fitted with extra heavy steel flanges riveted together, and Ludlow valves are used entirely. From the steam drum runs a 7-inch steam pipe connecting with the engines, also making a vertical bend, so as to procure dry steam and allow for expansion and contraction. All the steam pipes and connections are covered with magnesia, supplied by Nightingale & Childs, of Boston.

THE ENGINES.

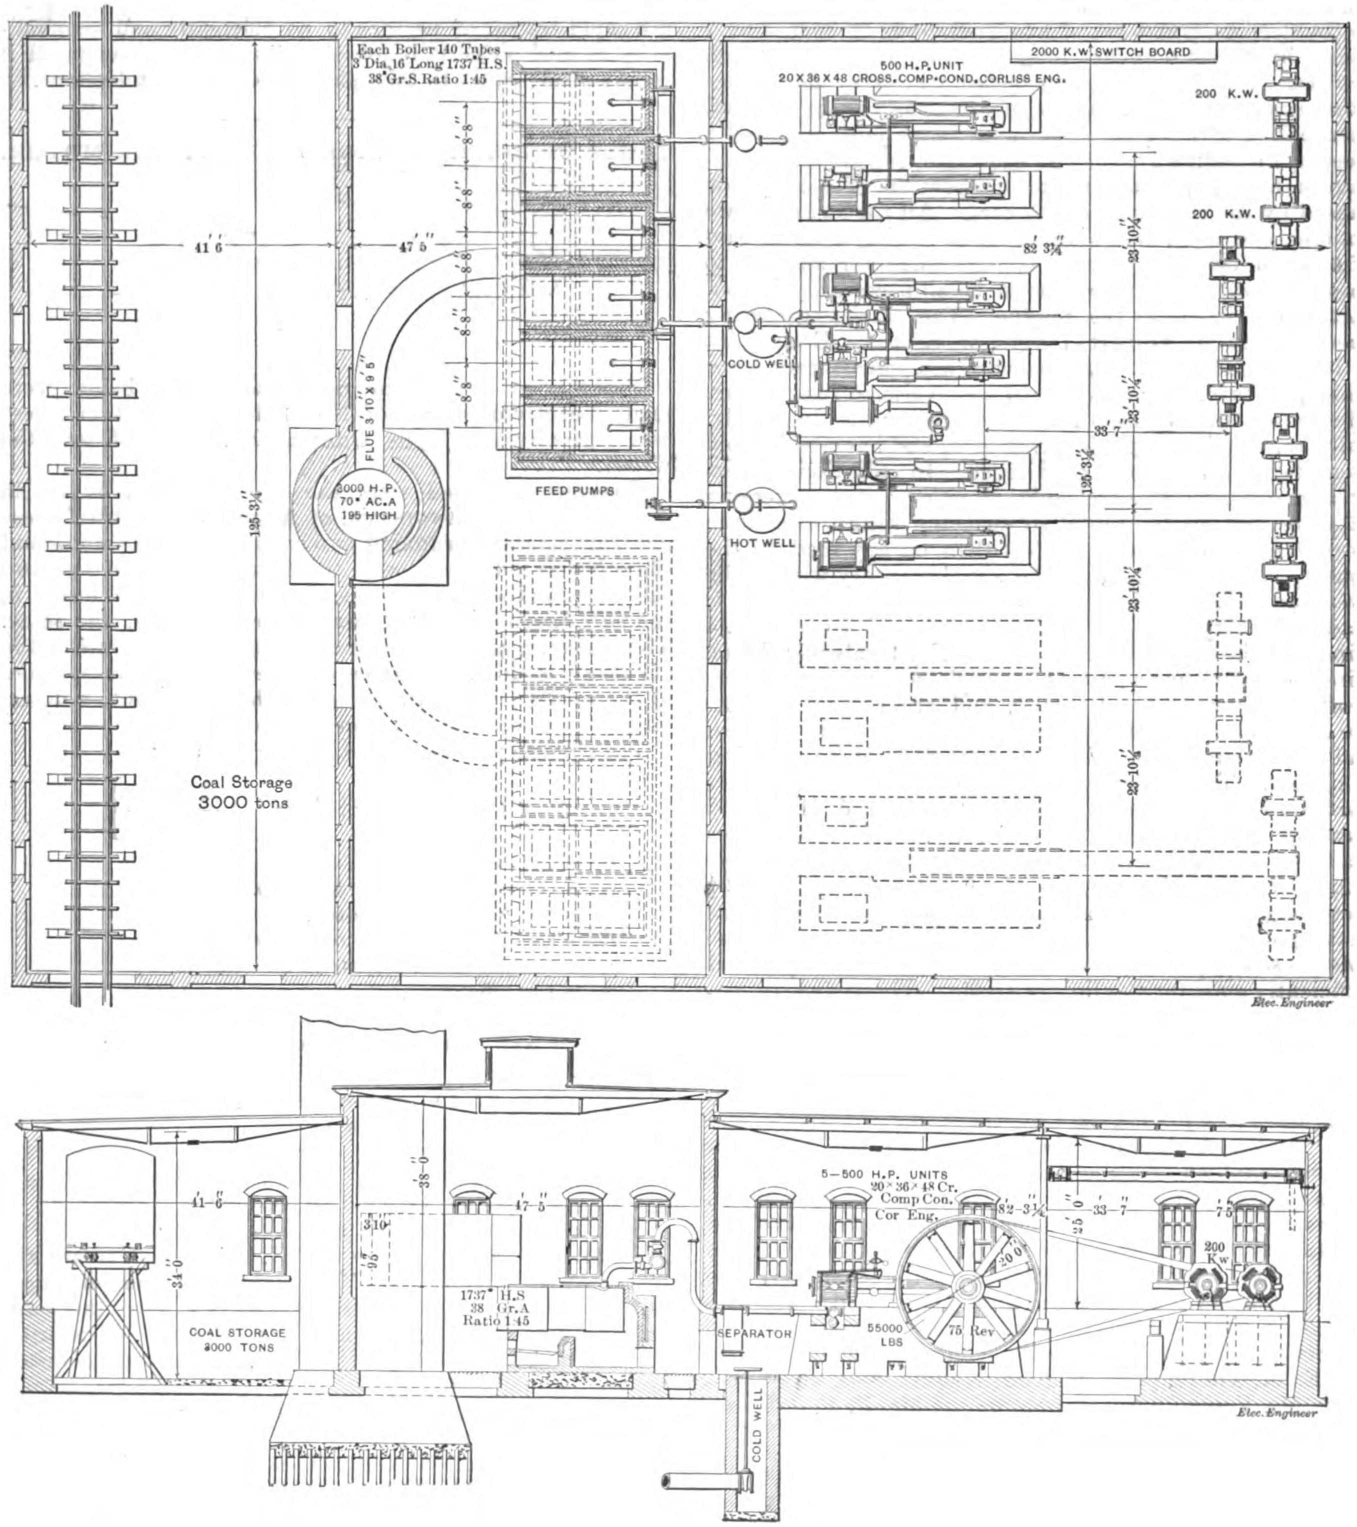
Cooper-Corliss engines have been adopted, manufactured by C. & G. Cooper & Co., of Mount Vernon, Ohio, two of which are at present running, and a third is now being installed. They are cross-compound condensing engines with cylinders 20-inch and 36-inch diameter by 48-inch stroke. The fly-wheel is 20-foot diameter, by 48-inch face, weighs 55,000 pounds, and makes 75 revolutions per minute. The cylinders are steam jacketed, and between the high and low-pressure cylinders is a multitubular reheater. In the basement of the building, each engine has connected with it a Deane 500 h. p. condenser and pump combined, and a 500 h. p. National feed water heater, made by the National Pipe Bending Company, of New Haven, Conn. The pipe connections between the cylinders of the engines and the condenser have been made in such a way that every possible way of running the engines may be attained, should any trouble arise with either the condensing or heating apparatus. For instance each side of the engine can be run high-pressure and exhaust direct into the atmosphere, with or without the feed water heater, or the engine can be run condensing with or without the feed water heater: in all nine possible combinations may be used, so that it is almost impossible for any accident to necessitate shutting down the engine, unless an actual break-down of the engine itself. The fly-wheel of the engine is belted direct to the pulley of the generators, a 46-inch double-ply belt manufactured by Josiah Gates & Sons, of Lowell, being used. The foundations of the engines are of brick 31 feet long by 8 feet wide by 9 feet deep, which rest on a solid granite foundation laid in cement 5 feet thick and extending 125 feet, the whole width of the building.

THE GENERATORS.

The arrangement of the generators is quite new, two 200-kilowatt Thomson-Houston generators being driven from the same belt, and situated on the same bed-plate, the pulley for driving them being on a shaft in alignment with the armature shafts and connected thereto by means of two Hill clutches, one for each generator. The bed-plate for the two generators measures 26 feet over all, and supports rigidly the bearings of the generators and the driving pulley. Each generator is fitted with self-adjusting and self-oiling bearings. Immediately under the bed-plate of the generators is a brick foundation 28 feet long at the top by 8 feet wide and 8 feet deep, which in turn rests on a heavy granite foundation resting on the clay, 30 feet long by 10 feet wide and 4 feet deep.

THE SWITCHBOARD.

The dynamo switchboard is of solid slate mounted on a skeleton frame of wood and is made in 10 sections, one for each generator. On each section is mounted two circuit breakers, one 650 ampere ammeter, one dynamo switch, rheostat and lightning arrester. All the connections are on the back of the board, and are made with clamps and screws. The feeder switchboard is also of slate mounted on a skeleton frame of wood, and is equipped with the Ajax switches with fuse attachments, manufactured by A. & J. M. Anderson, of Boston. The board is divided into eight sections, representing eight different sections of the city. Some of these sections have one feeder only, and some have two, three or four, according as the traffic is heavy or light in that section. Each feeder is provided with an ammeter and a 200-ampere Ajax switch, there being room on each section for four ammeters and four switches.



General Plan and Sectional Elevation of the Station.

OUTSIDE CONSTRUCTION.

Having thus described the power house, a few details about the outside construction will be found interesting, especially as there are some novel features, never before used on electric railway work. The general plan of the outside work was devised by Mr. P. F. Sullivan, the general manager of the company, from several years' experience with the Lakeview road. At present there are about 40 cars in operation; all being fitted with two 15 h. p. W. P. motors, mounted on Bemis trucks, and equipped with series multiple controllers. The track construction is all of the newest type, the Wharton 90-pound girder rail 9 inches deep, manufactured by William Wharton, Jr., & Co., of Philadelphia, being used. These rails are spiked direct on to the sleepers, which are of kyanized spruce, 5 inches by 7 inches by 6 feet 6 inches long, and laid on 2-foot 6-inch centres. The joints are connected by heavy fish plates fitted snug, and making a shoulder bearing for the rail, and then bolted with six bolts, and under each joint is placed a sleeper, in addition to one at each side, so that every precaution has been taken for the prevention of loose joints caused by the pounding of the cars. All the switches are trailing, and are 7 feet long, the cars having a wheel base of 6 feet 6 inches, so that it is impossible for any car to throw a switch, all four wheels being necessarily in contact at one time with the tongue. The track engineering was done by Mr. Gilbert Hodges, of Boston. Each joint is double bonded and connected with a supplementary wire, which, in turn, is connected to an overhead return wire. The use of this overhead return is new, and is due to Mr. Sullivan, who is greatly in favor of it, and has used it from ideas derived from past experience. In addition, sinkers or large ground plates are sunk in canals or rivers wherever they are met in the route, so that the return circuits in Lowell are to-day more perfect than on any road in the country. Connection from the supplementary wire to the overhead return, which varies from No. 0 to No. 0000, is made at every fifth pole. The track bonds are of No. 4 wire, and the supplementary wire is No. 1 galvanized iron wire. The wires connecting the supplementary to the overhead return are of No. 4 copper, and are run up through the iron poles. All the overhead wires are triple braided, and were made by the Washburn & Moen Manufacturing Company. The trolley wire is No. 0 throughout and is of hard-drawn copper, also made by Washburn & Moen and guaranteed 98 per cent. conductivity. Walworth poles made by the Walworth Manufacturing Company, of Boston, are used in the city, the No. 2 extra heavy size, 29½ feet long, being used, except at the curves where extra heavy poles are required. In the suburbs a Georgia pine pole is used in place of the iron pole as being cheaper and sufficiently good for the lighter traffic. The trolley insulators and clips are of the Thomson-Houston type, and the strain insulators and pole insulators are made of the well-known Ætna material, and manufactured by A. and J. M. Anderson, of Boston. The poles are thus doubly insulated from the trolley wire, first by the trolley insulator and then by the Anderson swivel pole insulator. The span wire is composed of three No. 8 steel wires, and the guard wires are made of No. 9 wire, being supported by two No. 8 wires. The whole work has been done in a first-class and substantial manner, and reflects great credit not only on the engineers but on the officials of the company, who have lent every assistance in their power and spared no expense to make their electric system as perfect as any in the States. The officers of the company are at present: Mr. E. M. Tucke, president; Mr. August Fels, vice-president; Mr. Percy Parker, treasurer; and Mr. P. F. Sullivan, secretary and general manager.

THE ELECTRIC RAILWAY vs. TELEPHONE IN GERMANY.

With regard to the electric street tramway at Halle, says the London *Railway World*, one very noteworthy and interesting fact to be commented upon is, that the tramway authorities have successfully fought and conquered in the customary pitched battle with the telephone interests, represented in this instance by no less a power than the German Government. However, the courts of law have maintained clearly that the use of an earth return as part of any electrical circuit is quite open to telegraphs, telephones, or electric tramways; and if one is found to interfere with another, then the latter must adopt a different method of completing its circuits than through the earth, if it desires a change at all. Such a decision appears to be given purely on public grounds; the idea apparently being that it is, at least, equally important for the rapid transit of persons to be efficiently and economically carried on as it is for the transit (we cannot call it rapid) of messages to take place through the telephone.

TESTS OF A SPRAGUE NO. 6 STREET CAR MOTOR.

BY

Cary T. Hutchinson

The tests of which the results are given below were made recently on a pair of No. 6 double-reduction street car motors by Dr. Louis Duncan, Mr. Carichoff and the writer.

The methods used were the two described by me in The Electrical Engineer, of August 31. In brief these methods consist in running two machines, one as motor and the other as a dynamo, with the field strengths of the two the same, and at the same speed; this makes all losses in the two, except the $C^2 R$ loss in the armature, the same. The efficiency is deduced for a standard resistance; *i. e.*, the efficiency is deduced for certain resistances, irrespective of the actual state of the motor. This amounts to a determination of efficiency at a certain temperature.

The efficiency is calculated by the formula:

$$\varphi = \tfrac{1}{2}\left[1 + \frac{C_2}{C_1} - (C_1 + C_2)\,\frac{R_0 + r_0}{E}\right]$$

C_1 is the current in the motor.
C_2 is the current in the dynamo.
E is the P. D. at the motor.
R_0 is the standard field resistance.
r_0 is the standard armature resistance.
φ is the efficiency.

This motor, in service, is regulated by commutating the fields, as is well known; the switch positions are:

I. A + B + C.
II. B + C. (A short-circuited).
III. B + C. (A cut-out).
IV. (A in parallel with B) + C.
V. A in parallel with B. (C short-circuited).
VI. A in parallel with B. (C cut-out).
VII. A in parallel with B in parallel with C.

It will be seen at a glance that I, IV, and VII are the running positions; II and III have the same ampere-turns as IV, but higher resistance; V and VI have the same ampere-turns as VII, but higher resistance. It is little short of criminal to run on III or VI, yet this was common practice at one time.

Following are the data for these motors:

Rating: 15 B. H. P.

Armature: Drum; 56 divisions, each wound with 8 turns 14 B. W. G.; 56 bars in commutator.

Fields: Three coils on each leg; each coil has 11 layers, each of 31 turns 14 B. W. G.

The standard resistances to which all results are reduced are for I, 11.5 ohms; IV, 6.1 ohms; VII, 2.15 ohms. These include the armature resistance; this latter varies from .75 to .93 ohm; the field resistances at different temperatures vary 40 per cent. Ampere-turns for I, 2046 × current; IV, 1364 × current; VII, 682 × current.

Gearing ratio is 11.77.

$$\text{Armature flux} = 6.7 \times 10^6 \frac{\text{counter E. M. F.}}{\text{revolutions per minute}}.$$

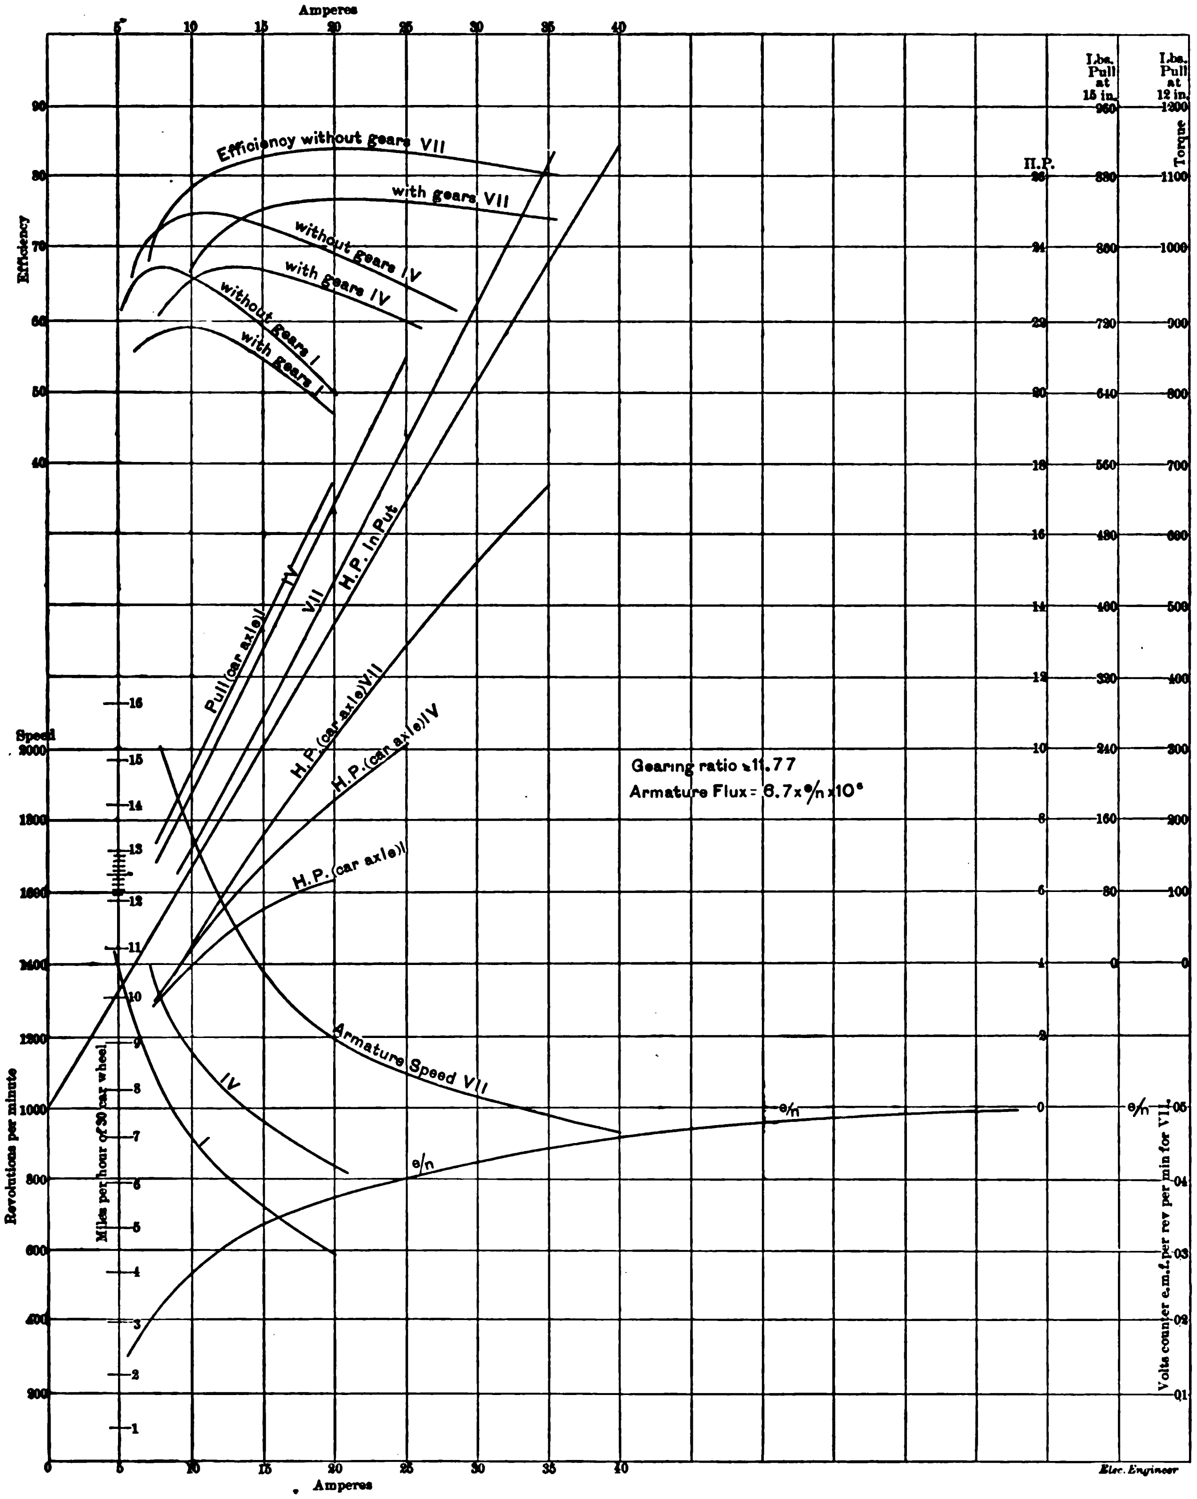
$$\text{Armature induction} = \frac{\text{armature flux}}{335}.$$

$$\text{Miles per hour, for 30-inch wheel} = \frac{\text{armature speed}}{132}.$$

The general dimensions are:

Bore of poles	10	inches
Diameter armature, over all	9	"
Length poles	10¼	"
Diameter of core	8¾	"
Gap	⅝	"

The curves in the accompanying diagram give the results. The six curves in the upper left hand corner are the efficiencies, with and without gears, for the I, IV and VII positions. The three lines below give the pull at the car axle for the three positions; below is the curve of input; still lower are three curves showing output for the three positions. Then come the speed curves, and at the bottom, extending across the sheet is the characteristic of the machine, plotted in terms of volts generated ÷ revolutions per minute, as ordinates, and current values as abscissæ. Current × 682 gives ampere-turns.



Tests of a Sprague No. 6 Street Car Motor.

THE FIRST ELECTRIC RAILWAY POWER STATION IN NEW YORK CITY.

TOWERING away above the tallest trees some distance from the Boston road near West Farms, may be seen the round top of a new brick chimney, over two hundred feet high and 16 feet in diameter at its base. This massive pillar of brick marks the location of the first and only electric railroad power station in New York City. At this station electricity is generated for supplying power to the Harlem Bridge and Fordham electric railroads and its branches, at present about twenty miles of double track and trolley wire, all operated by the Union Railway Co.

The power house is a brick building 200 feet long by 75 feet wide; the roof is supported by an iron truss frame. A 75-foot traveling crane rolls on an iron track which forms the top of the walls extending the whole length of the building. The crane has a lifting and carrying capacity of 30 tons. It was used in hoisting and placing the heavy parts of the engines and dynamos and is intended for general repair work in the future.

The station is equipped with four 500 h. p. Babcock & Wilcox water tube boilers, supplying steam to four large Cooper compound condensing Corliss engines of 400 h. p. each, with driving wheels 20 feet in diameter and 41-inch face, having a speed of 72 revolutions per minute. Belted direct to these engines are four 300,000-watt Thomson-Houston, multipolar generators. These machines are all insulated from the earth by being leveled up 1 inch from the firm concrete foundation and the space filled up with melted sulphur, which forms a solid bed around the base of the dynamo, insuring perfect insulation and a permanent anchorage.

It will require the power of but two generators to operate the road equipped at present, and a relay of two machines will be kept in readiness to start at a moment's notice should anything happen to either engine or dynamo in operation.

The station has been built of sufficient size to permit the railroad company to double the present power plant and not move or change any of the completed work. Several miles of the road operated by this company runs under the elevated structure of the Suburban Railroad Company on Third avenue, where no poles are needed as the trolley wire is supported from the iron structure of the elevated road.

A plank 1 inch thick and 10 inches wide with strips screwed to its edges—forming a wide inverted groove, is bolted to the angle iron of the elevated structure, and the trolley wire is fastened to the plank by a special insulator, every 12 or 15 feet about 3 inches below the grooved plank.

This acts as a guard to keep the trolley from striking the iron structure should it leave the wire, and also removes every possibility of the wire coming in contact with the iron above. The caution that has been exercised in making a perfectly insulated trolley wire reduces to a minimum the possibility of its ever falling to the street. About thirty cars are now running. These are all equipped with the Thomson-Houston single-reduction motors. The handsome cars were made by the St. Louis Car Co., of St. Louis, Mo.; the trucks are of the Peckham manufacture.

Mr. L. H. McIntire, formerly of the General Electric Co., is consulting engineer of electrical construction. His office is in the Union Railway Company's office, 2388 Third avenue, New York.

It may be added that the cars have been crowded with passengers from the outset, and that it is frequently very difficult to get any footing on them so thickly wedged together are the passengers. Work is being rapidly pushed on a number of the new lines in the district, and each will go into operation speedily.

Since the above was written, Mayor Grant has declined to approve the Ninth Avenue Trolley Line in this city.

MISCELLANEOUS.

ON THE LAW OF HYSTERESIS (PART II) AND OTHER PHENOMENA OF THE MAGNETIC CIRCUIT.[1]

BY CHARLES P. STEINMETZ.

IN a former paper "On the Law of Hysteresis"[2] the author has shown that the energy converted into heat during a complete cycle of magnetization can be expressed by the empirical formula,

$$H = \eta B^{1 \cdot 6},$$

where $\pm B$ is the maximum magnetic induction reached during the cycle process, and η a "coefficient of hysteresis." He has given the numerical values of this coefficient, η, for different materials, varying for: Wrought iron, between .002 and 0045; cast iron, .016; annealed steel, .008 to .012; hardened steel, .025 to .082 in manganese steel; magnetite, .020.

He has also shown that this "coefficient of hysteresis," η, is apparently independent of the speed of reversal within practical limits, being the same for slow reversals as for rapid alternations up to somewhat over 200 complete periods per second. The tests published covered the whole range, from very low magnetization, $B = \pm 85$ lines of magnetic force per cm.^{2} up to saturations as high as $B = \pm 19{,}000$ lines of magnetic force per cm.^{2} giving fair agreement with the law of the 1.6th power.

Under conditions where eddy or Foucault currents were induced in the iron, the loss of energy followed the more general formula,

$$H = \eta B^{1 \cdot 6} + \varepsilon N B^2,$$

where N is the frequency, H the whole loss per cycle and cm.^{3} in ergs or absolute units, and $H_1 = \eta B^{1 \cdot 6}$ represents the loss by molecular hysteresis; $H_2 = \varepsilon N B^2$ represents the loss by eddy currents.

To determine the loss of energy in a magnetic cycle between two limits B_1 and B_2 the author made a number of tests: 1. By the electro-dynamometer method, by employing *pulsating* currents for the excitation of the magnetizing helices; that is, currents which were derived by the superposition of an alternating and a continuous E. M. F. 2. By means of the Eickemeyer differential magnetometer, described in the former paper.

The electro-dynamometer tests were carried out after the manner illustrated in Fig. 1. By this method the voltmeter directly measures the E. M. F. induced by the fluctuation of the magnetism, that is, measures these fluctuations, while the wattmeter measures the time integral of the product of instantaneous values of main current into variation of magnetism, that is, the energy given off to the iron.

Fig. 2 gives the curve of hysteresis, with the values observed by means of alternating currents marked by crosses +, the values observed by pulsating currents marked by circles. The average value of magnetization, $\frac{B_1 + B_2}{2}$, is written in the figure in kilolines. The dotted curve is the magnetic characteristic.

These tests prove that *the energy dissipated by hysteresis depends only upon the difference of the limiting values of magnetic induction, between which the magnetic cycle is performed, but not upon their absolute values, so that the energy dissipated by hysteresis is the same as long as the amplitude of the magnetic cycle is the same, no matter whether the cycle is performed for instance between values of the magnetization,* $B_1 = +4000$ and $B_2 = -4000$; or $B_1 = +6000$ and $B_2 = -2000$; or $B_1 = +8000$ and $B_2 = 0$; or $B_1 = +14000$ and $B_2 = +6000$.

In either case the hysteretic loss is the same, since the magnetic variation is the same, $B_1 - B_2 = 8000$. *Hence the general form of this empirical law of hysteresis is*

$$H = \eta \left(\frac{B_1 - B_2}{2} \right)^{1 \cdot 6},$$

where B_1 and B_2 are the values between which the magnetism varies, η a constant of the material, in our case = .0035.

Including the energy dissipated by eddy-currents, we derive

$$H - \eta \left(\frac{B_1 + B_2}{2} \right)^{1 \cdot 6} + \varepsilon N \left(\frac{B_1 - B_2}{2} \right)^2,$$

where N is the frequency, ε a coefficient of eddy-currents.

The magnetometer tests were made by means of the Eickemeyer differential magnetometer. In determining the magnetic characteristic, before each test the magnetizing current, and therefore the magnetism, was reversed repeatedly to destroy the remanent magnetism left from former readings, and always *first readings with lower, than with higher magnetization, were taken to make sure that the remanent magnetism of the former test*

---

[1] Abstract of a paper read before the American Institute of Electrical Engineers, Sept. 27, 1892.

[2] THE ELECTRICAL ENGINEER, Jan. 27, 1892, *et. seq.*

would be destroyed by the reversal of magnetism in the following test. The hysteretic curves were taken by varying the magnetizing current cycle and taking readings at every step.

The conclusion derived from these tests is the same as that derived from the electro-dynamometer tests, namely, that the loss of energy by hysteresis can be expressed by the equation

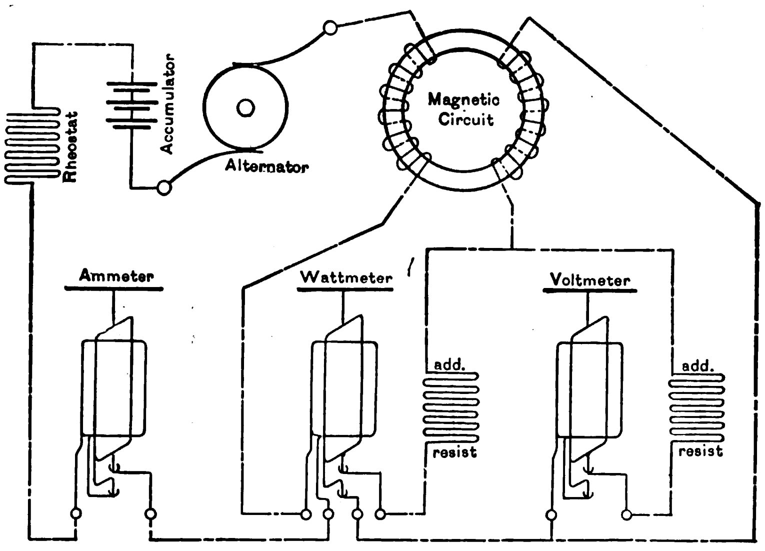


FIG. 1.

$$H = \eta \left(\frac{L_1 - L_2}{2}\right)^{1.6}.$$

Hence the magnetic properties of this cast iron can be expressed by means of the equations

$$\rho = \alpha + \sigma F, \quad H = \eta \left(\frac{L_1 - L_2}{2}\right)^{1.6},$$

and by three constants, α, the "*coefficient of magnetic hardness;*" σ, the "*coefficient of magnetic saturation;*" η, the "*coefficient of magnetic hysteresis.*"

Only for values of $F \leqq 20$ the value of ρ, the metallic reluctivity, if determined by *reversals* of magnetism, is larger and may necessitate the introduction of a term, $c\, e^{-\delta F}$, or of similar shape.

The term α Mr. Steinmetz calls the "coefficient of magnetic hardness," since the value of α determines what is called "magnetically hard." He shows, also, that α is smallest in soft Norway iron, increases by hardening and reaches very large values in hardened steel. The term σ he calls the "coefficient of magnetic saturation," because $L_\infty = \frac{1}{\sigma}$ is the value of absolute saturation of the metallic induction, that is, the value which the metallic induction reaches for infinitely large M. M. F's., that is, for values larger than $F = 1000$ to $20{,}000$ (according to the value of magnetic harness α).

A large number of tests were made upon Norway iron, wrought iron, mitis iron, annealed cast steel, ferrotype iron. Norway iron was shown to be the softest metal magnetically, while mitis metal behaves almost exactly like wrought iron. Tests of mitis metal showed that for all practical purposes it may be considered magnetically as identical with ordinary good wrought iron. Cast steel was shown to be far superior to ordinary good wrought iron and almost approaches Norway iron. Tests were also made on amalgams of iron and nickel, and porous iron obtained by evaporating the mercury from the amalgam; also upon magnetite and cobalt. The author also discusses some of the tests of Ewing, and refers to the article by Kennelly published in THE ELECTRICAL ENGINEER of April 6, 1892, in which that investigator proves the existence of the law of the 1.6 power to hold good for the hysteresis of nickel.

The following conclusions are arrived at as the results of these tests:

1. The dissipation of energy into heat by molecular hysteresis, during a complete cycle of magnetization performed between the limiting values of magnetic induction L_1 and L_2, is expressed by the formula

$$H = \eta \left(\frac{L_1 - L_2}{2}\right)^{1.6},$$

where L_1 and L_2 very likely have to represent the metallic magnetic induction,

$$L = B - H = 4 \pi I,$$

while, when eddy—or Foucault—currents are induced by the cyclic variation of magnetization, the dissipation of energy is given by,

$$H = \eta \left(\frac{L_1 - L_2}{2}\right)^{1.6} + \varepsilon N \left(\frac{B_1 - B_2}{2}\right)^2$$

where the first term is the loss by molecular hysteresis, the second term the loss by eddy-currents, and N denotes the frequency.

2. Beyond a certain minimum value of M. M. F. F_m, the metallic magnetic reluctivity, ρ (and consequently the inverse value of susceptibility, κ, which is, $\frac{1}{\kappa} = \frac{16 \pi^2}{10} \rho$) follows the linear law,

$$\rho = \alpha + \sigma F$$

Below this minimum value of M. M. F. F_m first the curve of alternating, then that of rising magnetism drop below, while the curve of decreasing magnetism rises above the curve derived from the linear law, $\rho = \alpha + \sigma F$.

3. Beyond a certain minimum value F_m, that is for medium and high M. M F.'s. all the main features of the magnetic properties of materials can be expressed by three constants, α, σ, η,

α, the coefficient of Magnetic Hardness,
σ, the coefficient of Magnetic Saturation,
η, the coefficient of Magnetic Hysteresis.

Instead of α, σ and η the three constants may be used,

$L_\infty = \frac{1}{\sigma}$ the value of absolute magnetic saturation.

$F_0 = \frac{\alpha}{\sigma}$ that M. M. F., where half-saturation $\frac{L_\infty}{2}$ would be reached if the linear law of reluctivity holds already for F_0.

$H_\infty = \eta\, L_\infty{}^{1.6}$ the maximum value of hysteretic dissipation of energy, for absolute saturation.

Then we have the equations:

RELUCTIVITY,

$$\rho = \alpha + \sigma F = \frac{F_0 + F}{L_\infty}$$

HYSTERESIS,

$$H = \eta \left(\frac{L_1 - L_2}{2}\right)^{1.6} = H_\infty \left(\frac{L_1 - L_2}{2 L_\infty}\right)^{1.6}$$

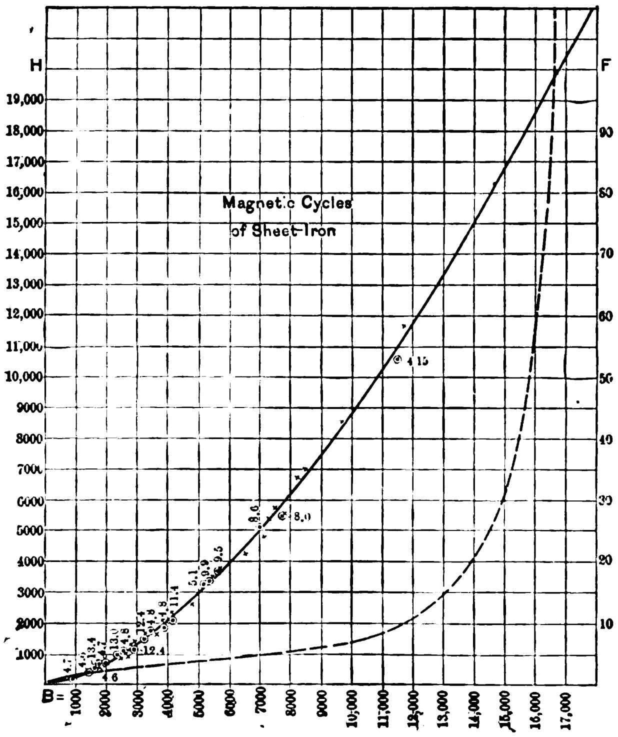

FIG. 2.

In the latter case the exponent 1.6 only covers an absolute number, while the coefficient of hysteresis H_∞ is of the dimension "work" or "energy," = (cm.^{2} g sec^{-2}).

4. These formulas hold for all kinds of wrought and cast iron and steel, for nickel, and magnetite, and most likely for amalgam of iron, hence apparently for all magnetizable materials.

For air simply σ and $\eta = 0$, $\alpha = 800$.

Fig. 3 shows the magnetic characteristics of the most interesting of the materials tested.

The author gives the following tables regarding the magnetic constants and properties of average materials.

MAGNETIC CONSTANTS OF AVERAGE MATERIALS.

MATERIAL.	Coefficient of			Absolute saturation	$F >$ =
	Mag. hardness a	Mag. saturation σ	Mag. hysteresis η	L_∞	
Average wrought and sheet iron, soft annealed cast steel and mitis metal......	.3	.055	.008	18.2	7
Average cast iron, cast steel of low permeability...	2.4	.095	.018	10.5	18
Average soft steel, hard cast steel of high permeability	1.33	.06	.02	16.7	40
Average glass-hard steel.................	8	.1	.07	10.0	90

Tests were also made on coiled wire, laminated iron and iron filings for all of which the law was found to hold true.

The looped curve of hysteresis measures the energy expended by the M. M. F. during a complete cycle. It has been assumed then, that the area of this loop represents the energy consumed by molecular friction in the iron. This, the author asserts to be a fallacy. The area of this looped curve is not the energy dissipated by molecular friction in the iron. Warburg and Ewing have shown—the former by supposing the cycle of M. M. F. performed by changes in the position of steel magnets, and determining the energy expended in performing these changes in position; Ewing by supposing the magnetic cycle produced by a cyclic variation of the exciting current in a magnetizing helix and calculating the energy consumed by the E. M. F.'s induced in the magnetizing helix by the cyclic variation of magnetic induction—that the energy expended by the M. M. F. during a complete cycle is equal to the area of this looped curve.

Hence, it has been concluded that the area of this loop represents the energy expended by molecular friction in the iron. Here is the mistake in the conclusion. For :

MAGNETIC PROPERTIES OF AVERAGE MATERIALS.

"The area of the looped curve of hysteresis represents the energy dissipated by molecular magnetic friction then, and only then, when during the magnetic cycle neither energy is exerted upon the magnetic circuit by another source of energy, nor work done by or in the magnetic circuit."

Instances of the first case have been observed—and frequently misinterpreted.

That the law of the 1.6th power holds, proves, that this law does

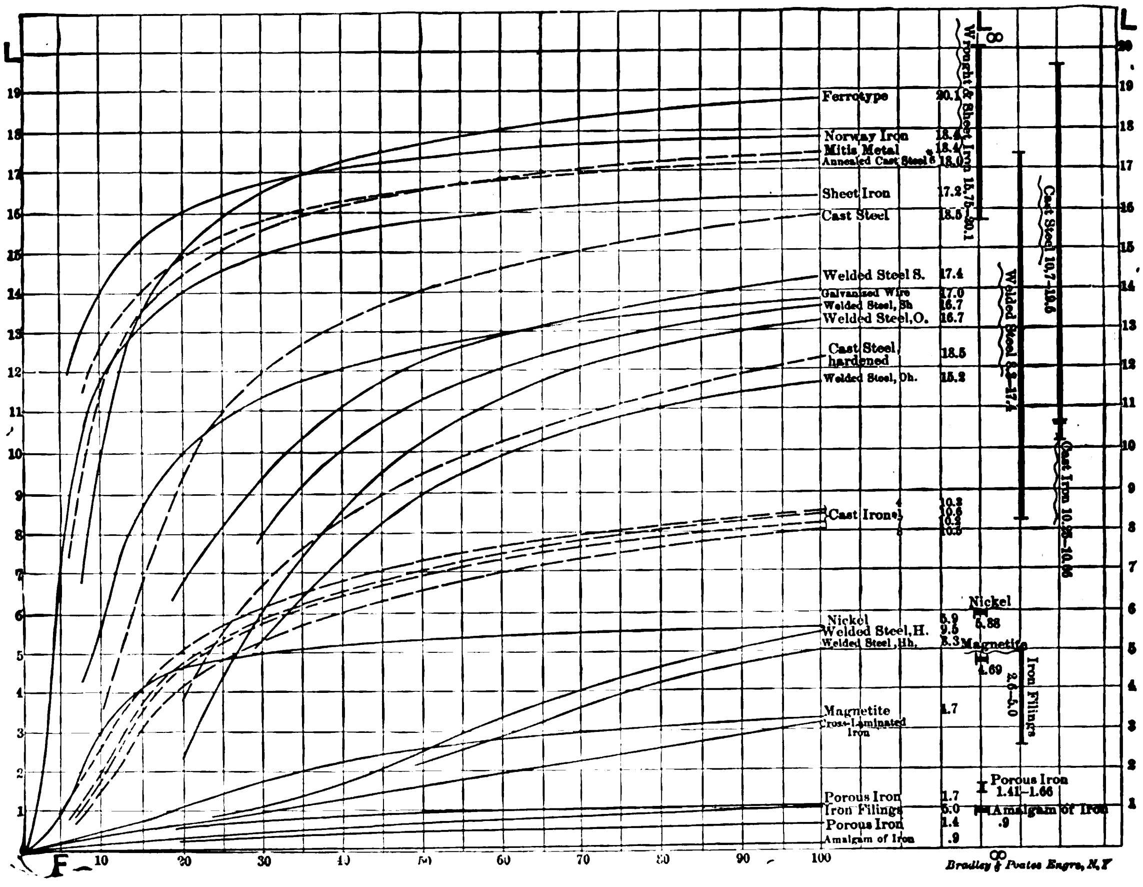

FIG. 3.

not depend upon a particular constitution of the material, but is of more general meaning. It is highly probable, that the initial inward bend of the magnetic characteristic, and the deviation of the metallic reluctivity from the linear law caused thereby, is merely due to the expenditure of energy by M. M. F. for molecular friction, and that consequently, if the energy of molecular friction is derived from another source, for instance mechanical vibration, the magnetic reluctivity follows the linear law from the beginning, as observed by Ewing, and the inward bend of the magnetic characteristic disappears.

The author finally discusses the theory of molecular magnets, pointing out that the kinetic theory of gases, thermo-dynamics, etc., make the theory of Ewing untenable, as all these theories lead to the conclusion that the dimensions of molecules are infinitely small compared with their distances apart; whereas Ewing assumes the distance of the centres of molecular magnets to be not much greater than their length.

The final conclusions of the author are as follows:

As a rough approximation, the magnetic induction and the molecular friction depend upon the M. M. F. by the law of probability of molecular distances. The point of maximum increase of induction is not the same as the point of maximum increase of molecular friction, since different factors enter into the function of probability.

The law of hysteresis, of the 1.6th power, is the interdependence of two functions depending upon the same law of probability, hence can be of simpler form than either function.

THE SECOND ANNUAL MEETING OF THE AMERICAN ELECTRO-THERAPEUTICAL ASSOCIATION.

THE AMERICAN ELECTRO-THERAPEUTICAL ASSOCIATION held its second annual meeting at the New York Academy of Medicine, 17 East Forty-Third street, on the 4th to the 6th inst., inclusive. The exercises consisted of executive sessions, the reading and discussion of papers, and set discussion upon predetermined subjects, after the custom of the German medical congresses. The last feature was an entire innovation and met with enthusiastic praise. In connection with the convention an exhibit of electro-medical apparatus was made by leading manufacturers of the country. The officers for the past year have been: President, Dr. W. J. Morton; vice-presidents, Dr. Augustin H. Goelet, Dr. Wm. F. Hutchinson; secretary, Dr. Horatio R. Bigelow; treasurer, Dr. R. J. Nunn; executive council, Dr. G. Betton Massey, Dr. Robert Newman, Dr. A. D. Rockwell, Dr. W. H. Walling, Dr. H. E. Hayd.

FIRST DAY'S PROCEEDINGS.

On Tuesday, Oct. 4, the meeting was called to order at 10 a. m., when an executive session was held and new members elected. The president, DR. WILLIAM JAMES MORTON, then delivered the opening address.

ADDRESS OF THE PRESIDENT.

The president, after a few introductory remarks, called attention to the fact that electro-therapy has been sadly overlooked and ignored by the medical profession, and left too long to the designing, the ignorant and the incompetent, with the natural result that a certain contempt is felt by the public for the methods of these men, generally not physicians, and hence for the science which they dishonor. This discredit of so important a branch of the medical profession, he said, will disappear with a higher education, and a consequent purging of electro-therapy from mystery by those whose labors are undertaken in a purely scientific spirit. And now, said the speaker, a glance at where we stand to-day. As a result of the changes which have worked themselves out in industrial and commercial relations the electrical engineers have arisen, self-taught, and acquiring science as they need it. In advance of them the new science has sprung into being. Electricity has emerged from its thraldom, cast aside the restraints of the class-room and become a part of practical life. Now it has invaded the realm of medicine, and the physician is turning to the physics of electricity and acquiring the lore of the electrical engineer. We welcome the electrical expert. To-day an exact science, electricity, knocks at the door of medicine, an inexact science, and demands a hearing. In the onward march of measures for the relief of crippled humanity I see electro-therapeutics struggling to the vanguard. There are positive pillars of fact upon which that faith is based.

Instances were then cited of the effect of electricity in the excitation of the living protoplasm, in electrolysis, in cataphoresis, and the familiar vaso-motor effects were mentioned. It is not improbable, said the speaker, in conclusion, that a final contest in the cure of diseases is between the physical phenomena we term electric and the chemico-biological processes of metabolism exhibited by the animal cell; between electricity on the one hand, which in the human body by electrolytic conduction becomes a chemical process, and, on the other hand, the chemical processes which constitute life in the organism—chemistry against chemistry.

Reports were then read from the Committees on Standard Cells, Standard Meters, and Arrangements, after which the first paper, on The Use and Abuse of Electricity in Medicine, was read by DR. A. D. ROCKWELL, of New York. Dr. Rockwell strongly advocated the use of the electric current in certain forms of treatment, by physicians skilled in its application, and severely condemned the injudicious and unskillful trifling with an agent so powerful for good or ill. He exhibited a patient who had been thrown down and dragged by a railway train, sustaining injuries which caused partial paralysis and totally unfitted him for any manual work, and who had so far recovered, under electric treatment, that he has resumed his old employment of baggage handler.

The Rôle and Range of Electricity in Therapeutics, by DR. T. W. POOL of Lindsay, Ontario, was read by title, the author being absent.

A paper by DR. G. APOSTOLI, entitled New Contributions of the Electrical Treatment (both Faradic and Galvanic) to the Diagnosis in Gynæcology, was read by Dr. Hutchinson. Dr. Apostoli has probably done more to advance practical electro-therapeutics than any one else, and the paper, consisting principally of reports of actual cases treated by him was listened to with great interest. The fact was brought out that painful and mutilating operations can frequently be avoided by the use of the current in diagnosis. A long discussion followed the reading of the paper, during which the various forms and materials of electrodes for medical use were considered.

The afternoon session commenced with the reading of a paper on A New Treatment of Prostatic Hypertrophy, by DR. G. B. MASSEY, of Philadelphia. A discussion upon "Electric Cataphoresis and its Practical Application as a Therapeutic Measure" was opened by DR. FREDERIC PETERSON, of this city. Dr. Peterson stated that he had made experiments and counter-experiments upon himself with substances applied to the skin alone, with electricity alone; with drugs upon the anode and upon the cathode, and all details had been carefully recorded, the possibility of error due to personal equation had then been eliminated by expermenting upon patients. The results have since been published in the *N. Y. Medical Journal* of April 27, 1889, and Nov. 15, 1890; the *N. Y. Medical Record*, Jan. 31, 1891; and the *Phil. Times and Register*, March 21, 1891. The speaker said that his discussion brought together the results of the use of cataphoresis in various lines of practice. Great interest centres also in the nature of the physical process by which substances are thus diffused, and accordingly Mr. A. E. Kennelly and Prof. E. J. Houston were called upon to read papers upon the subject from the standpoint of the electrician and the physicist.

MR. A. E. KENNELLY being absent, his paper entitled "On the Physics of Cataphoresis," was read by Dr. Peterson. The author stated that the cataphoric action of electric currents, sometimes called electrical endosmose, was discovered by Reuss in 1807. Wiedemann, in 1852, described the laws controlling the action, which were corroborated later by Freund and others. When two liquids are brought into communication through a narrow channel and an electric current is passed, a flow accompanies the current in the same direction from positive to negative. In rare instances this flow is in the opposite direction. The total quantity of liquid depends on the quantity of current. Wiedemann found the rate of transfusion approximately proportional to the resistivity of the aqueous solution of any given salt.

The explanation of cataphoresis is based upon the same electrostatic force and motion by which Thales first placed electricity upon record, and by which pith balls, etc., are made vehicles of energy when electrified. It seems to be a general law that the contact of any two dissimilar substances gives rise to an electrification and difference of potential between them. In the case of a glass tube containing a homogeneous liquid and subjected to a steady current, the liquid particles next the glass receive a charge and are moved along the tube. This moving force accelerates the particles until the friction due to their velocity balances the moving force. This will determine the rate of electric transfusion through the tube for the particular strength of current employed. If a porous diaphragm be regarded as a framework supporting a number of tubes the principle will be the same.

When it is desired to produce the greatest transfusion the solution should be as weak as possible to increase its resistivity, since pure water is nearly a non-conductor. Wiedemann showed that, roughly, the transfer of liquid was inversely proportional to the percentage of solid contacts. This, however, is not strictly true and the rule is not clearly defined. On one hand the conductivity of an aqueous solution of salts generally increases more slowly than the percentage of solid contents, and, on the other hand, the effect of the increasing strength of the solutions upon their contact electrification is not yet clearly determined. A large and inviting field seems to be open here for experimental research, for, although the theory of cataphoresis appears to satisfactorily explain the facts, the measurements that have been yet made with standard diaphragms and solutions seem all too few.

PROF. E. J. HOUSTON, of Philadelphia, next took the floor, and presented a paper upon the same subject. The author commenced by defining cataphoresis, and added that cataphoric action. Porret's phenomenon, electric endosmose, electro-capillary phenomena, electro-vection, and electro-filtration may be considered synonymous terms. He quoted Becquerel as saying that exosmose is due partly to diffusion and partly to filtration.

After citing a number of phenomena due to osmotic action, the action of the electric current flowing through the liquid and the porous wall or septum was considered. In this case a movement of the liquid takes place in the direction of the current, that is, the level of the liquid rises on the side of the negative electrode and falls on the positive side. Regarding the skin or other membranes of the body as septa, if electrodes moist with medicinal substances be applied to different parts of the body, and a current passed, a flow of the solutions takes place by means of which they are carried into the tissues of the body. This action, the author considered from a physicist's standpoint, and mentioned the work of Reuss, the first observer, Porret, Graham, Napier, Dutrochet, and De la Rive. After quoting from the works of these experimenters he said, in effect, The problem of extending the field of electro-physiology belongs to the electro-therapeutists. To me, as a physicist, it seems that whenever a constant electric current is passed through the body a cataphoric action must go on. The result must be to engorge certain parts and deplete other parts, and it is possible that the value of the treatment may arise mainly from such action in many cases, by the transportation of morbid matter from one place to another. This probably explains why so often only one electrode acts therapeutically, while the other is indifferent. Again, the resistance of the body cannot remain uniform, since cataphoric action presumably accompanies the passage of the current, and since the cataphoric action increases with the strength of the current, the resistance of the body will vary with the strength of the current employed to measure such resistance. This does not refer to change resulting from polarization.

In conclusion, the author called attention to the two varieties of cataphoric action; normal, by means of which a disturbance of the distribution of the constituents of the body is effected by the passage of an electric current, and abnormal, by whose means fluid substances are introduced into the body from without by the passage of a current.

Dr. Morton then called attention to the fact that electrolysis and cataphoresis act together in many of the phenomena frequently attributed solely to cataphoresis. He left out of the discussion the application of cataphoresis to surgery, etc., and devoted himself to cataphoric medication and demedication, electric baths, etc.

The discussion upon the uses of cataphoresis in general surgery, in the absence of DR. W. H. WALLING, of Philadelphia, was read by title, and after a short paper by DR. A. H. GOELET, of this city, upon its uses in gynæcology, the discussion was closed by Dr. Peterson who read a paper on cataphoresis in nervous diseases.

EVENING SESSION.

In the evening DR. R. J. NUNN, of Savannah, Ga., read a paper on "Stable Electrodes; Old Materials Newly Arranged." He preferred a pad of woolen or cotton cloth moistened with water as an electrode. Dr. Massey said that white clay had the advantage of being alkaline. Other materials were also advocated. Prof. Houston suggested the mixing of graphite with the clay to increase the conductivity. The discussion was closed by some general remarks by Dr. Nunn.

A paper on "The Value of Voltaic Alternatives in Optic Nerve Atrophy," by DR. C. E. RIGGS, of St. Paul, Minn., was read by title. "The Present Status of Electrolysis in the Treatment of Strictures," by DR. ROBERT NEWMAN, of this city, was postponed, as Dr. Newman was confined to his house by illness, and the evening session closed with the reading of a paper on "Some Phases of Neurasthenia and their Treatment," by DR. W. F. ROBINSON, of Albany.

After the evening session the members of the Association headed by President Morton, visited the Electric Club and were entertained, "lunch and punch" having been provided. The reunion was very enjoyable, and was kept up until the small hours of the morning.

WEDNESDAY—MORNING SESSION.

A paper on "The Need of Greater Simplicity and Uniformity in Electro-Therapeutic Apparatus" was read by DR. W. J. HERDMAN, of Ann Arbor, Mich. He called attention to the necessity of adopting standards for every piece of apparatus used in electro-therapeutical work, and discussed the various forms of current for medical uses. Especial stress was laid upon electrodes. Dr. Hutchinson said that the present electro-medical apparatus was altogether too complicated, and urged simpler apparatus.

A paper postponed from Tuesday evening entitled "A Contribution to the Electrical Treatment of Cystic Goitre and Hydrocele," and also a "Note on Psoriasis" was read by DR. C. R. DICKSON, of Toronto, Canada. A long discussion followed.

A paper entitled "Medical Electricity from an Electrician's Standpoint" was then read by MR. J. J. CARTY, electrician of the Metropolitan Telephone Company. Mr. Carty first stated that there should be a thorough understanding of terms between electricians and physicians, which at present does not exist. "Faradism," he said, is referred to in medicine in a narrow sense. It applies to the current generated in induction coils. "Galvanism" in medicine refers to the current obtained from a battery, and "Franklinism," to effects produced by discharges from Leyden jars and static machines. The differences between these three "isms" is one of degree only. The term "resistance" has lost its original significance, as it differs according to the current used, and various other conditions.

It can be safely asserted that the resistance of an inorganic body, using "resistance" in its broadest sense, is different for every degree and form of current. Taking this view of the case, a more intelligent selection of currents for the human system can be made. Some parts of the body may possess high self-induction, while others obey the ordinary laws of conductivity, and still others may act as condensers. If the periodicity of the current is of so much importance ordinarily, it would seem that it must be of some account in the highly organized human system, and yet we hear little of the periodicity of Faradic currents or of their characteristic curves. After calling attention to the work of Clerk Maxwell in support of the electromagnetic theory of light and the recent experiments of Hertz, the author referred to Tesla, whose labors have opened such an enormous field for research and spoke of the peculiar effect of the Tesla electric bombardment. In closing, he quoted Siemens as saying, after the experiments of Hertz: "Electricity has annexed the whole domain of optics," and added the hope that the labors of the Association may be so crowned with success that some day electricity will annex the whole domain of medicine.

During the discussion on this paper Mr. Carty illustrated his remarks upon the blackboard, and Dr. Kellogg made some sketches showing work done by him in determining Faradic curves.

DR. W. F. HUTCHINSON, of Providence, R. I., next read a paper on "Anæsthetical Electricity," in which he called attention to the value of galvanism to allay pain, and the benefit of using a current in connection with medical treatment.

AFTERNOON SESSION.

In the afternoon the first paper read was one on "Some Physiological Experiments with Magnets at the Edison Laboratory," by DR. FREDERICK PETERSON and MR. A. E. KENNELLY.

After a few words in regard to the effect of magnetism upon certain forms of hysteria, etc., and quoting Profs. Benedikt, Roberts, Bartholow and Dr. Vansant on the subject, the authors described experiments made by them with magnets of great power at the Edison laboratory at Orange. The pole-faces of the magnet, which two men were required to lift, were 1.2 cm. apart, and between these poles objects were placed for observation. The intensity of the field was about 5,000 C. G. S. lines per square cm. A drop of water on a glass slide in this field was visibly distorted. Experiments were made on blood, which was found to be unaffected in any way. Experiments upon frogs failed to give any result. Then the effect of a continuous current was noted, and circulation was found to cease. Benedikt's statement that magnetism will produce paralysis was then tested. A set of idle field magnets converging into a cylinder two feet in diameter and seven inches deep was employed. In this cylinder a dog was placed for five hours without the slightest visible effect. Experiments were next tried upon the brain. The armature and one journal were removed from a dynamo converting about 70 h. p. at full load, and in the space between the pole pieces the subject placed his head. The intensity of the magnetic field produced was about 2,500 C. G. S. lines per square cm. A switch was arranged to open and close the exciting circuit. Sphygmographic tracings, taken continously, showed no change in regularity. The respirations were not changed in the least, and there were no sensations that could be attributed to magnetic influence. Experiments in connection with reversed magnetism also failed to show any effect upon the subject. From these experiments, the authors conclude that the human organism is unaffected by the most powerful magnets known to modern science; that neither direct nor reversed magnetism exerts any perceptible influence upon the iron in the blood, upon the circulation, upon ciliary or protoplasmic movement, upon sensory or motor nerves, or upon the brain.

A discussion was then held upon "The Relative Fœticidal Value of the Galvanic and Faradic Currents in Ectopic Gestation," on which the following points were emphasized:

How does electricity destroy the life of the fœtus? Which current should theoretically be more certain in its results? And what is the individual experience? Can electricity be depended upon to accomplish the desired end, and why? Should the galvanic current be used interupted or constant? What is the best method of applying the agent? What are its dangers? And how are they to be avoided? Who should apply it? Can it be safely intrusted to the general practitioner?

The discussion was opened by Dr. A. D. ROCKWELL, and continued by DR. WM. T. LUSK, DR. ALEX. J. C. SKENE, DR. FRANKlin H. Martin, Dr. Augustin H. Goelet, Dr. A. Lapthorn Smith, Dr. A. Brothers, Dr. Malcolm McLean, Dr. E. H. L. McGinnis, and Dr. A. H. Buckmaster.

After this subject had been exhausted, papers entitled "The Treatment of Salpingitis by Depletion and Drainage Secured by Electricity," by Dr. Augustin H. Goelet, of N. Y.; and "The Negative Pole of the Galvanic Current an Aid to Uterine Development, with Cases," by Dr. Charles G. Canaday, of Roanoke, Va., were read.

"Some Successes and Failures with Electricity in Gynæcology," by Dr. A. Lapthorn Smith, of Montreal, Canada, was then read by title, Dr. Smith being absent.

EVENING SESSION.

At the executive session, which opened the evening's proceedings, the following officers were elected for the coming year: President, Dr. A. H. Goelet, of New York; first vice-president, Dr. W. F. Hutchinson, of Providence, R. I.; second vice-president, Dr. W. J. Herdman, of Ann Arbor, Mich.; secretary, Dr. Margaret A. Cleaves, of New York; treasurer, Dr. R. J. Nunn, of Savannah, Ga. After the transaction of business a delightful reception was tendered the Association and guests by the resident members, where, during supper, many toasts were drunk to the continued success of the society, and to the individual retiring and incoming officers. During the evening a lecture on "The Phonograph and Microphonograph" with illustrations was given by Dr. J. Mount Bleyer of this city. The principles on which the instruments are worked was discussed, and the history of their invention alluded to. Reference was made to the use of the microphone for medical purposes to discover minute sounds inaudible to the unaided ear, such as the heart beats of a patient afflicted with catalepsy, the circulation of the blood in the arteries, etc. The treatment of deafness by means of the phonograph was also described, as well as the making of phonographic records of the voice in throat diseases for purposes of comparison.

THURSDAY—MORNING SESSION.

The proceedings on Thursday morning opened at 10 o'clock with the reading of a memorial of the late Dr. Gilman Kimball, by Dr. Ephriam Cutter, of New York. A paper on "Recent Experiences on the Treatment of Myomas" by Dr. G. Betton Massey of Philadelphia was then read and discussed.

The paper on "The Present Status of Electrolysis in the Treatment of Strictures," by Dr. Robert Newman, of this city, which was read by title during the first day's proceedings owing to the illnes of the author, was then read by Dr. Nunn, and its discussion postponed until the evening session.

On Thursday afternoon the members of the Association, at the invitation of Mr. Edison, visited the laboratory at West Orange, where they were received by Mr. A. E. Kennelly and his assistants, and spent two highly interesting hours in strolling about the extensive buildings and inspecting the various forms of apparatus. Dr. Belyer here gave a practicable demonstration of the phonograph and covered several cylinders with records of the voices of the visiting physicians.

EVENING SESSION.

The evening session commenced with a discussion upon Dr. Newman's paper on the treatment of strictures, read by Dr. Nunn at the morning session.

Dr. J. H. Kellogg, of Battle Creek, Mich., read a paper on "The Physiological Effects of Magneto-Electricity of Regular Variations" or sinusoidal current. The author began by referring to M D'Arsonval's studies upon the physiological effects of the alternating magneto-electric current, and quoted his statment that "The intensity of the motor, or sensory, reaction is proportionate to the variation of the potential at the point excited." The author some years ago experimented with a small magneto-electrical apparatus, or telegraph generator, and found that this machine produced powerful but painless muscular contractions. He then made an apparatus for graphically representing currents, from which many tracings from the machine referred to and also various forms of Faradic machines were made. A number of these curves were shown. That due to the Faradic current was uneven with respect to the zero line, while that of the magneto-elebtric machine corresponded exactly with those obtained by D'Arsonval. The comparative painlessness and great penetrating power of the sinusoidal current were especially emphasized. An induced current capable of producing equally strong contraction is so painful as to be almost intolerable, and the same is true with current from a static machine. Experiments upon the effect of this current on the sense of taste, the olfactory sense and the auditory sense are now in progress. The effect upon the optic nerve is attributed to its remarkable power of diffusion or penetration. Dr. Kellogg's device for the graphic representation of the curves consists of an electromagnet arranged to form an annular field in which a delicate solenoid is made to move by an alternating current. This solenoid, acting on the short arm of a delicate lever, compels the long arm to scribe its movements upon a rotating cylinder covered with smoked paper. As Dr. Kellogg was unfortunately called away immediately upon the presentation of his paper, no discussion upon it was possible. Dr. John A. Cutter, of this city, next read a paper entitled "Electro-Therapeutics and the Systemic Treatment of Morbid Growths," and Dr. F. von Raitz, also of New York, one on "Lacerations of the Cervix Uteri and Their Treatment."

A "Note upon a New Application of Alternative Sinusoidal Currents in Gynæcology," by Dr. G Apostoli, and "The Electrical Treatment of the Paralysis Due to Acute Poliomyelitis," by Dr. Graeme M. Hammond, were read by title, after which Dr. S. T. Anderson, of Bloomington, Ill., closed the literary part of the proceedings by the presentation of a paper on "The Constant Current in Glaucoma and Cataract." Mr. J. J. Carty took part in the discussion that followed.

In accordance with Dr. Herdman's suggestion, the president appointed the following committees: Committee on Standards of Static Machines, Drs. Kellogg, Cleaves and Massey. Committee on Constant Current Generators and Controllers, Drs. Peterson, Herdman and Newman. Committee on Electrodes, Drs. Rockwell, Nunn and Dickinson.

Dr. Morton, the retiring president, in a few words summed up the proceedings of the Association, and expressed his gratification at the progress made and the bright outlook for the future. The attendance throughout the convention was much larger even than had been hoped, and the papers presented showed an interest in the subject in hand that augured a bright future for the Association itself and great benefit to humanity at large through a more perfect understanding of the proper place and use of electricity in medicine. In retiring from office, Dr. Morton introduced the new president, Dr. Goelet, after whose brief address of acceptance, Dr. Nunn moved a vote of thanks to Dr. Morton for his efficient and untiring work in behalf of the society, and the meeting adjourned.

The next convention will be held in Philadelphia, on Sept. 10, 1893, immediately following the meeting of the Pan-American Congress of Physicians.

EXHIBITS.

In the hall immediately adjoining that in which the convention was held, a number of the leading instrument makers of the country showed electro-medical apparatus in great variety.

Messrs. J. H. Bunnell & Co. exhibited a number of dry battery outfits for physician's use.

Mr. Otto Flemming, of Philadelphia, had on exhibition some portable galvanic batteries with controller and milliamperemeter attached, and a combination apparatus for galvanic and Faradic currents. A portable Faradic battery, with three secondary coils, was also shown, as well as a set of carbon electrodes, of which he is the sole manufacturer.

The McIntosh Battery and Optical Co., the Eastern agents for whom are Messrs. Oelschlaeger Bros., 42 East Twenty-third street, this city, had an interesting exhibit of table batteries and electrodes. An improved Töpler-Holtz machine was also shown, for which some strong claims are made. This machine is the only one of its kind in existence.

The Edison Manufacturing Co. exhibited a number of Edison-Lalande batteries, and a complete standing cabinet for medical use. A phonograph, with a 14-way hearing attachment, was also in operation, and the contents of a number of excellent cylinders were given to the visitors during the course of the convention.

Messrs. Geo. S. Davis, of Detroit, had on exhibition a number of publications upon electrical subjects as applied to medicine.

The Jerome-Kidder Mfg. Co. showed a new form of portable gynaecological coils made for the Electro-Therapeutic Society. Various instruments devoted to this field of service were also shown, as well as cabinets and portable galvanic batteries.

The Ozone Mfg. Co., 47 Liberty street, showed one of their machines in operation.

Messrs. J. C. Vetter & Co., 104 East Twenty-third street, showed their standard milammeters, carbon current controllers, incandescent current adapters, Leclanché dry batteries, etc.

The Ford Surgical Instrument Co., 315 Third avenue, exhibited the Gibson storage battery, for which they are special agents, as well as a large number of electrical instruments. This company make a specialty of getting up special forms of instruments for particular uses.

Dr. H. E. Waite, president of the Waite and Bartlett Mfg. Co., 143 East Twenty-third street, was present with a large electrostatic machine, claimed to be one of the most perfect in existence.

The Law Battery Co. showed one of their electro-therapeutical outfits, for which extensive claims are made.

The Galvano-Faradic Manufacturing Co., of 300 Fourth avenue, this city, exhibited a number of medical batteries, together with battery-cabinets and appliances.

LETTERS TO THE EDITOR.

THE IMPORTATION OF SUBMARINE CABLES.

I HAVE followed with much interest the discussion in your valuable journal on the question of importing submarine cable into America for the United States Government. I quite agree with your correspondents in believing that there is no need to go outside the United States for a cable only seven miles long. At the same time I do not think any American manufacturer could turn out an armored cable forty or fifty miles long as Mr. Marsh suggests. All the factories that I know of in America are inland, or at any rate they are not conveniently situated for water transportation, and the difficulties of storing, handling and transporting a cable of such length would be insuperable.

In the second and third paragraphs of his letter Mr. Marsh goes quite wide of the mark. He is in error in stating that all submarine cables of great length have been laid by foreign companies "generally under subsidies from foreign governments." By far the greater proportion of the submarine cables of the world are owned by English telegraph companies and in the majority of cases government subsidies do not form an important part of the revenue; in any case the subsidies only guarantee a certain amount of government traffic. Most of the cables owned by foreign governments have been paid for outright and form part of the regular telegraph system of the country to which they belong.

It is obviously impossible that a demand can exist *in* the United States for long submarine cables, and as submarine cables are usually laid down in the deep sea it is equally impossible that American manufacturers can be protected by an "import tariff on the finished article."

There is a great deal more in the submarine cable industry than is implied in the airy expression of "putting in a plant." It is an industry that has been built up in all its branches by years of dearly bought experience, and the difficulties of starting an American cable factory, Minerva-like and completely equipped for handling large contracts, are so serious that even the most enterprising manufacturers have been quite content to see American orders for many thousand miles of cable go across the water.

HERBERT LAWS WEBB.

LONDON, ENG. Sept, 19, 1892.

PATENTS ON ENAMEL INSULATORS.

REGARDING enamel rheostats, cooking apparatus, and all other electrical apparatus with conductors imbedded in enamel, we wish to call your attention to a decision of the Commissioner of Patents, copy of which we enclose herewith. As owners of the Morford patents, which we propose to protect, we feel that you are entitled to know our rights in connection therewith, and believe you will respect them regarding any infringements.

P. H. GUNCKEL,
Attorney, Enamel Insulator Co.

CHICAGO, ILL.

(The document sent us is a copy of the decision of the Commissioner of Patents in the case of Morford *vs.* Carpenter, on the appeal of the latter from the decision of the Examiners-in-Chief awarding priority of invention to Morford with reference to the following interference issue: "In an electro-heating apparatus, the combination with the heated surface-plate and the resistance, of a coating of enamel, or its equivalent, securing the resistance to, but insulating it from said plate." The Commissioner upheld the award to Morford.—EDS. E. E.)

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED SEPT. 27, 1892.

Alarms and Signals :—

Circuit Closer for Railroad Crossing Signal Mechanism, I. W. Loy and R. O'Toole, Mechanicstown, Md., 483,231. Filed Nov. 6, 1891.

Has for its object to automatically close a circuit for the purpose of giving a signal on the approach of a train.

Electric Bell, N. H. Raymond, Buffalo, N. Y., 483,309. Filed Aug. 29, 1891.

Employs a porcelain base and an electromagnet whose frame is seated in a recess in front of the base and secured thereto.

Electrical Annunciator, N. H. Raymond, Buffalo, N. Y., 483,310. Filed Sept. 26, 1891.

Employs a U-shaped sheet metal, provided with stiffening wires and having the armature pivoted on one wire and the drop on the wire at the opposite side of the frame.

Conductors, Conduits, and Insulators :—

Electric Cable, T. Guilleaume, Cologne, Germany, 483,285. Filed May 5, 1892.

Employs a strip of non-conducting material twisted about its own axis to form spiral grooves in which the conductors lie.

Coupling for Underground Wires, J. J. Purcell, Washington, D. C., 483,327. Filed Feb. 16, 1892.

Employs two sleeves, one upon each end of the cables to be connected; having respectively right and left hand threads on their abutting ends, and a nut having corresponding threads.

Dynamos and Motors:—

Electric Motor, W. M. Dresskell, Brainerd, Minn., 483,431. Filed June 23, 1891.

Has for its object a motor which may be operated by an alternating or direct current in which the sections at the commutator may be readily removed and replaced without disarranging any of the adjustments of the machine.

Heating:—

Electric Heater, T. Ahearn, Ottawa, Canada, 483,124. Filed April 4, 1892.

Employs a tube of heat-conducting material about which the heating wires are wound, and an outer metallic tube; the annular space being packed with powered fire clay or like material.

Measurement :—

Method of Measuring the Strength of Magnets, C. H. Rudd, Chicago, Ill., 483,168. Filed Nov. 6, 1891.

The method consists in balancing the magnetic field by a counter magnetic field generated by an electric current, which is measured and compared with the current required to balance a standard magnet.

Electric Meter, A. G. Waterhouse, Hartford, Conn , 483,189. Filed January 4, 1892.

A meter in which the current is measured by the collection of gas and its discharge from a receptacle.

Metal Working :—

Process for Electric Welding, C. L. Coffin, Detroit, Mich., 483,423. Filed Dec. 11, 1891.

Consists in heating the metal by an electric current, upsetting each of the heated parts at a point back of the point of welding and not at the plane of junction, and then bringing the parts into contact and passing a heating current, after which the parts are pressed together.

Electric Metal Working Device, C. L. Coffin, 483,424, Detroit, Mich. Filed Dec. 11, 1891.

Employs a clamp for holding the article to be worked and carrying a die and a movable conductor for applying pressure.

Process of Electric Metal Welding, C. L. Coffin, Detroit, Mich., 483,425. Filed Jan. 21, 1892.

Process of electrically welding sheets of metal by supporting over the seam a metal plate, between which and the junction of the two plates an arc is formed.

Process of Electric Metal Heating, C. L. Coffin, Detroit, Mich., 483,426. Filed Jan. 26, 1892.

Consists in simultaneously subjecting the metal at different points to the action of separate arcs whose heating power varies in approximate proportion with the respective cross-sections of the material at the points to which they are applied.

Electric Metal Working, C. L. Coffin, Detroit, Mich., 483,427. Filed Feb. 6, 1892.

Consists of a converter having a broken secondary and means for inserting the piece to be welded within the core of the transformer so as to complete the secondary.

Process of Electric Metal Working, C. L. Coffin, 483.428. Filed Feb. 8, 1892.

Claim: Process of heating metal consisting in subjecting the opposite sides of the metal simultaneously to the action of voltaic arcs alternated in position.

Miscellaneous:—

Means for Controlling the Operation of Mechanisms, H. E. Vineing, Roseville, N. J., 483,272. Filed Feb 27, 1892.

Has for its object to enable an operator at a central station to control any one of a number of mechanical devices independently of the others.

Watchman's Electric Time Recorder, N. H. Raymond, Buffalo, N. Y., 483,308. Filed Aug. 17, 1891.

Thermostat, I. F. Beers and F. C. Beers, Elmira, N. Y., 483,339. Filed March 7, 1892.

A device for regulating the draft of furnaces.

Railways and Appliances :—

Electric Locomotive, N. C. Bassett, Lynn, Mass., 473,204. Filed April 1, 1891.

Consists in so supporting a motor that its armature may be concentric with the axle of the locomotive.

Electric Railway System, A. L. Riker, New York, 483,366. Filed Dec. 22, 1891.

Employs a hollow rail of magnetic material inclosing a conductor also of magnetic material and resting normally on an insulated portion of the interior of the rail, and a magnetic device carried by the car to bring the conductor into electrical contact with the rail and with brushes for collecting the current.

Trolley Track Hanger for Electric Railways, W. Q. Prewitt, Lexington, Ky., 483,388. Filed Oct, 17, 1891.

Consists of two clamping members having an underlying flexible support and a channel between their adjacent edges to receive the track.

Electric Railway Conductor, R. M. Hunter, Philadelphia, Pa., 483,494. Filed Sept. 23, 1886.

The invention comprehends an overhead conductor supported from above and a car traveling beneath and provided with a trolley and arm for collecting current from the overhead conductor.

Switches and Cut-Outs :—

Electric Cut-Out and Switch Box, L. D. McMunn, Cromwell, N. Dak., 483,235. Filed April 5, 1892.

Consists in the combination with terminal plates for the lamp circuit of sliding contact blocks, a lever for operating them, and one or two pairs of dynamo circuit terminals with a short-circuiting bar between each pair.

Electric Snap Switch, S. F. Alden, New Bedford, Mass., 483,316. Filed Feb. 1, 1892.

Comprises four terminals composed of separate vertical plates, the opposite plates being connected, and a rotary shaft and brush adapted to be brought successfully into contact with the terminals.

Telephones and Apparatus :—

Automatic Coin Actuated Telephone, F. Muller, Berlin, Germany, 483,162. Filed Aug. 25, 1891.

Test System for Multiple Switchboards, C. E. Scribner, Chicago, Ill., 483,175. Filed Dec. 5, 1891.

The invention consists in including a condenser in each circuit in connection with the individual annunciator.

Test System for Multiple Switchboards, O. A. Bell, New York, N. Y., 483,506. Filed Sept. 30, 1891.

Employs line spring jacks having two line springs, contact anvils one for each line spring, and a test ring insulated from the line spring; two telephone lines including the springs respectively, a conductor joining all of the test rings, a branch from the conductor to one of the lines after it has included all of its line springs and contacts, and an earth connection to the line to which the branch extends.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

Advertising cheapens the cost of production by increasing the number of goods produced.

THE CARSTARPHEN ELECTRICAL RECIPROCATING TOOL.

THE CARSTARPHEN ELECTRICAL RECIPROCATING TOOL.

AMONG the more recent novel applications of electrical machinery designed to dispense with expensive hand labor, is an electrical "reciprocating tool" invented by Mr. Wm. P. Carstarphen, Jr., of Denver, Col. This tool is designed to do away with the mallet and chisel in the hands of the stone carver, and does its work by delivering a series of rapid blows upon the material to be shaped. For this purpose it is provided with a reciprocating plunger located and moving within two coils of wire through which a direct current of electricity is alternately passed. The current for operating the tool can be supplied from any suitable electrical source, such as an ordinary galvanic battery or a dynamo-electric current which is simultaneously switched from one coil or set of coils to the other by the use of a suitable mechanism located between the two coils, and controlled by the reciprocation of the plunger. The electrical current enters one end of the tool through a revolving swivel, and the rapidity of the strokes made by the plunger is regulated by a button on one side of the tool. In one model, which is a three-pound tool, the stroke can be made to vary from one-eighth of an inch to one inch, with a motion varying from 300 to 600 strokes per minute.

To operate a tool of this size but from four to six volts current are required. This makes it perfectly harmless to the operator, and as the wires enter the tool through a revolving swivel, there is no possibility of the wires becoming twisted while in use. Portable storage batteries 12 x 6 x 6 inches have been made, which are encased in a neat box and intended for operating the tool on scaffolds and elsewhere away from the shop. These have operating power sufficient for a day's work and can be recharged over night at an expense not to exceed 25 cents. Our engraving, reproduced from a photograph, shows the manner of manipulating the tool. With it, the carver or sculptor, instead of dividing a portion of his attention to striking his chisel, can devote his entire attention to the lines which he is following, thus producing more accurate and rapid work. It is estimated that the machine will produce work in one-fourth the time of hand work, and therefore a material reduction in the cost will be secured. We may add that Mr. Wm. M. Clark, Park Avenue Hotel, this city, has charge of the interest of the company in the East.

"THE ELECTICAL ENGINEER'S" EXTRA ON THE LAMP DECISION.

THE ELECTRICAL ENGINEER was the only paper that published last week the full and official text of the Edison lamp decision in the United States Circuit Court of Appeals. A stenographic version published by one of its contemporaries contained nearly 200 mistakes and omissions, many of which were of a most serious nature as confusing and perverting the sense. The official text in the ENGINEER eight page extra issued on Wednesday, was accompanied by a careful synopsis, and gave abstracts also of two other important electrical decisions handed down at the same time. Before Thursday night, over 15,000 of the extras had been printed and mailed. The demand from all parts of the country has continued large down to the present time, the ENGINEER'S enterprise being very generally appreciated.

THE BOGART ELECTRICAL APPARATUS FOR RETOUCHING PHOTOGRAPHIC NEGATIVES.

THE retouching of photographic negatives consists in deepening certain parts of the negative plate, where otherwise too great a quantity of light would pass through in the printing process, resulting in too strong shadows, or to correct mechanical faults or to modify strong natural peculiarities of the individual sitting for a portrait, such as wrinkles, moles and other facial defects or blemishes. The work itself is analagous to what is known as "shading" in ordinary pencil or crayon drawing, and consists essentially in filling in the ground by short parallel strokes of the pencil.

The electrical retouching apparatus consists of a cylindrical case, about the diameter of a thick pencil, and is provided at its end with the ordinary pencil clamp, which receives and holds the lead sharpened to a long point. The pencil clamp is not attached to the holder tube as usual, however, but to a metallic shaft which rotates freely within the holder, and however accurately the lead may be centered, the point, when rotating, will describe a small circle. Thus, if when the shaft is rapidly revolving, the holder be held upright and applied to any surface, a small circle will be the result of each application, the diameter of which will vary with the eccentricity of the setting. If, on the contrary, the holder be inclined at an angle and the point be applied, the holder being moved by the hand longitudinally in the direction of its axis, a looped spiral will result, the length of the loops depending on the speed of translation. If the angle which the instrument and surface make with one another be diminished, then only the under side of the pencil can act, and the result will be short parallel curved lines, whose distances apart depend upon the longitudinal movement. As the instrument is inclined more and more towards the surface, so do these parallel lines become less and less curved, approaching the straight line.

The pencil is rotated by a miniature electric motor attached to the top of the holder and operated by a small two-cell battery in connection with a flexible conducting cord. The entire weight of the instrument and motor is but three ounces. The hand is relieved of this weight even, by suspending the instrument by a fine long spiral spring supported when in use by a hook in the ceiling, or framework of the retouching table. The instrument is the invention of Mr. A. Livingston Bogart, of this city.

ELECTRICAL DEVELOPMENT AT ASPEN, COL.

THE ROARING FORK ELECTRIC LIGHT AND POWER CO., of Aspen, Col., is going in for extensive improvements. It is now building a new plant, designed exclusively for the purpose of furnishing power to the mines. It will use five Brush dynamos of 500 volts and 350 amperes each in its new plant, and will deliver the current by means of 225,000 pounds of No. 0000 copper wire. The dynamos will be driven by five 57-inch Pelton water-wheels, under 356-foot head, giving 250 h. p. per wheel. The water is brought from separate streams by means of a 30-inch pipe line 4,000 feet long, one 24-inch pipe line 3,900 feet long, a wooden flume 16,500 feet long and another 12,000 feet long. The shafting, floor stands and clutches are from the Hill Clutch Works. The iron roof and the traveling crane were furnished by the Berlin Iron Bridge Co. The officers of the company are H. P. Cowenhoven, president; D. R. C. Brown, vice-president; C. E. Doolittle, manager, and C. F. Brown, secretary. We are indebted to Mr. Doolittle, an old reader of THE ELECTRICAL ENGINEER, for these interesting details.

DETROIT ELECTRICAL WORKS.

THE DETROIT ELECTRICAL WORKS have secured the contract for the equipment of the Woodward avenue line of the Detroit Citizens' Street Railway Co., that city, notwithstanding the fact that great effort was made by the other companies manufacturing electric railway apparatus to secure same, and the awarding of the contract was largely due to the satisfactory manner in which the Jefferson avenue line, which was equipped a short time ago, has operated.

In addition to the above contract, the works have lately received an additional order (the sixth) from the Calumet Electric Street Railway Co., Chicago, and have also been awarded the contract for the equipment of the Consolidated Street Railway Company's lines at Salina, Kan.

Notwithstanding the fact that their factory has been enlarged so that the capacity is now three-fold what it was last year, the works are still crowded to the utmost with orders for their standard railway equipments, and also for railway generators.

MR. C. D. SHAIN, 136 Liberty street, in addition to his other agencies, will represent the Sunbeam Incandescent Lamp Co. in Eastern and Middle States. As stated last week, he is now Eastern agent for the Siemens & Halske Co. Mr. Shain is also selling agent for the Weston instruments and the Carpenter enamel rheostats.

A SHORT ELECTRIC STREET CAR AS A FREIGHT LOCOMOTIVE.

THE following data concerning the Short Electric Railway apparatus in operation on the Collins Park and Belt Line Railway Company, of Atlanta, Ga., will be of some interest to our readers:

THE SHORT ELECTRIC RAILWAY COMPANY,
Cleveland, Ohio.

Dear Sir.—The E. T. V. & G. R. R. delivered our generator at the W. & A. R. R. through an error. The W. & A. carried her out to the new water works, 10 miles from the city. Hunting her up and getting her back to the G. P. yards, delayed me in setting her up. Took her out to the power station last Friday evening. Unloaded her and set the base on Saturday. Put her together on Sunday. Wired her up on Monday and started her on Tuesday. The company here did not have an engine and it would have been very costly for me to haul the generator to the power station by wagon. Besides, some parts of the road would have had to be fixed up. In all I believe it would have cost $40 or $50 to haul her four or five miles to the plant. Therefore, I hitched an electric car to the flat car containing the generator and started for the plant. It made a heavy load, but I got there safely. On the steepest grade we went along faster than a man could walk and you know we have some pretty stiff grades on this road, fully 6½ per cent. I think. The motors got pretty warm but not more so than I have seen them during heavy traffic. The work done by them is remarkable and is the talk of the town.

(Signed) R. L. CALDWELL,
Expert in Charge.

Data concerning the trip is as follows :

Pennsylvania Railway Company car No. 5,653, weight....	29,150 lbs.
One Short 150 h. p. generator .. .. " ..	24,000 "
Total weight......	47,150 "

Between the Georgia Pacific Railroad Company and the power station of the Collins Park and Belt Railway Company there is one grade of 5 per cent. and another of 6½ per cent. The distance between the two points is 4½ miles. The motive power was one 16-foot open car body, equipped with two 20 h. p. single-reduction Short railway motors.

JOSEPH M. ZAMOISKI.

MR. JOSEPH M. ZAMOISKI, late of the Warfield Manufacturing Company of Baltimore, has been secured by the Ries Electric Specialty Company, of that city, as the manager of their construction department. The Ries Electric Specialty Company has now gone into the construction work in earnest and found themselves in need of an efficient manager, hence their employment of the gentleman above referred to. Mr. Zamoiski leaves his position as salesman for the Warfield Manufacturing Company, where he had worked up a reputation for himself in the successful installation of electric lighting plants complete. The Ries Company is already figuring on the complete electrical installation of a number of large and handsome buildings.

A $2,000,000 ILLUMINATING COMPANY FOR BALTIMORE.

THE General Electric Company has just succeeded in organizing an electric lighting company in the city of Baltimore, with $2,000,000 capital, whose plant will be unique. The central station will have no less than 10,000 h. p. For the central part of the city the 3-wire Edison system will be used ; for the suburbs, the Fort Wayne alternating system ; while the Fort Wayne arc lights will be used throughout where arc lights are required—all wires will be underground. The company will be under the management of Mr. J. Frank Morrison.

"INVENTIVE PROGRESS—BENEFITS OF THE AMERICAN PATENT SYSTEM."

MR. W. A. ROSENBAUM, the electrical expert and patent solicitor, of the Times Building, New York, has published under the above title a very interesting and beautifully illustrated pamphlet. It is a history in brief of the growth of our patent system, and gives a running account of many of the notable inventions fostered by it. There are group portraits also of patent commissioners and leading inventors, as well as pictures of the Patent Office.

BISHOP CABLE SELECTED FOR THUNDER BAY.

THE BISHOP GUTTA-PERCHA CO., of this city, have been notified that they are the successful bidders for the Thunder Bay cables about which THE ELECTRICAL ENGINEER recently contained so much interesting correspondence. The bids were opened at Washington on September 30, four being received for the six and a half miles of cable required. The Bishop Co. were the highest bidders, and were surprised at securing the contract. Preference would appear to be based strictly on the quality of the product. The Bishop samples were acknowledged to be far superior to the foreign. The Bishop Gutta-Percha Co. are to deliver the cable at Alpena and to furnish splicers, the Government paying the expenses of laying. It will cost a little over $8,000 laid.

SYRACUSE VOLTMETERS AND AMMETERS.

ON account of the great demand for voltmeters and ammeters in which are embodied the desired points of durability, accuracy, economy of power, dead-beatness and good finish, the Electric Engineering and Supply Company, of Syracuse, N. Y., are putting on the market instruments of the magnetic vane type. The principle is that of magnetic repulsion, controlled by a spring of great permanency by means of a large air vane of aluminum. The instrument is made quite dead-beat, and the pointer will come to rest much quicker than in the ordinary instrument of this class. The pointer is furnished with a good sized black dot to render the reading of the instrument possible at quite a distance. High resistance is aimed at in the voltmeters, and low resistance in the ammeters, thereby reducing the consumption of the power to a minimum. It is stated that with a fine finish and an accuracy unexcelled by the commercial instruments, they are worthy of a position upon the finest switchboards, as well as for portable work, and are guaranteed to do good service. They are put upon the market at a moderate price, and the demand for them is increasing daily.

THE KESTER ELECTRIC CO.

THE KESTER ELECTRIC CO., of Terre Haute, Ind., manufacturers of dynamos and motors, and whose advertisement will be found in another column, report a very good trade and say that the call for their incandescent dynamos is greater than ever before. They build all sizes of dynamos from 30 to 500 lights capacity which, owing to the care with which they are made, the high grade of material which is used in their construction and the method of compounding them, give them an efficiency and durability, it is claimed, surpassed by none. During the past summer this company sold a large number of 500-volt motors which are running by power furnished by street railway companies. The slow-speed, high-efficiency and noiseless running of these motors, coupled with the ease and reliability with which they can be operated, has created a large demand for them and they are compelled to run night and day to keep up with orders.

THE FORD-WASHBURN STORAGE BATTERY CAR.

THE storage battery car of the Ford-Washburn Storelectro Company of Cleveland, which has undergone so many successful tests in that city, will be on exhibition during the coming Street Railway Convention in Cleveland, October 19, 20 and 21. The delegates and visitors to the convention are cordially invited to ride on this car and its trailer and thoroughly inspect the working of same. It is believed that a storage battery car with a trailer will be quite a novelty.

C. & C. APPARATUS FOR THE WORLD'S FAIR.

THE C. & C. ELECTRIC MOTOR CO. have recently received an order from the chief of construction of the World's Columbian Exposition for two generators of 110 h. p. each, to be used to furnish current to the electric elevators that have been installed in the Administration Building on the Exposition grounds. These generators are to be in operation during the dedication ceremonies this month.

In addition to these machines, the C. & C. Co. has received orders for five more generators of 110 h. p. each, four of which are to furnish power to motors operated by exhibitors, and the fifth is for furnishing current for light.

NEW ENGLAND NOTES.

THE WAINWRIGHT MANUFACTURING CO. OF MASS. report the following list of sales of feed-water heaters. It will be noticed that one order was for 5,000 h. p. for the Atlantic avenue road in Brooklyn:

Chelsea Cordage Co., Boston, 700 h. p.; B. & M. R. R. Mystic Wharf Elevator, Charlestown, Mass., two 600 h. p. heaters; B. & M. R. R. Mystic Wharf Elevator, one 600 h. p. surface condenser; Massachusetts Charitable Mech. Asso., Boston, two 600 h. p. heaters; Robt. White & Co., Montreal, Can., one 150 h. p. surface condenser; A. F. Smith, Lynn, Mass., one 100 h. p. surface condenser; Ottumwa Electric Railway Co., Ottumwa, Ia., one 500 h. p. heater; J. A. Mumford, Hantsport, N. S., four 200 h. p. surface condensers; Ypsilanti Electric Co., Ypsilanti, Mich., one 200 h. p. heater; Elmira Silk Mills, Elmira, N. Y., one 200 h. p. heater ; Bay County Electric Co., Bay City, Mich., one 700 h. p. heater; Minnesota Iron Works, Soudan, Minn., one 700 h. p. heater; Mahanoy City, Shenandoah, Girardville & Ashland Electric Street Railway Co., Girardville, Pa., one 500 h. p. heater; H. M. Sciple & Co., Philadelphia, Pa., one 300 h. p. heater; Brooklyn and Atlantic Ave. Railway Co., Brooklyn, N. Y., five heaters, 5,000 h. p.; Ashland Electric Co., Ashland, Wis., one 500 h. p. heater; Mutual Compress Co., Montgomery, Ala., one 300 h. p. heater; Lynn and Boston R. R. Co. (second order), one 1,000 h. p. heater.

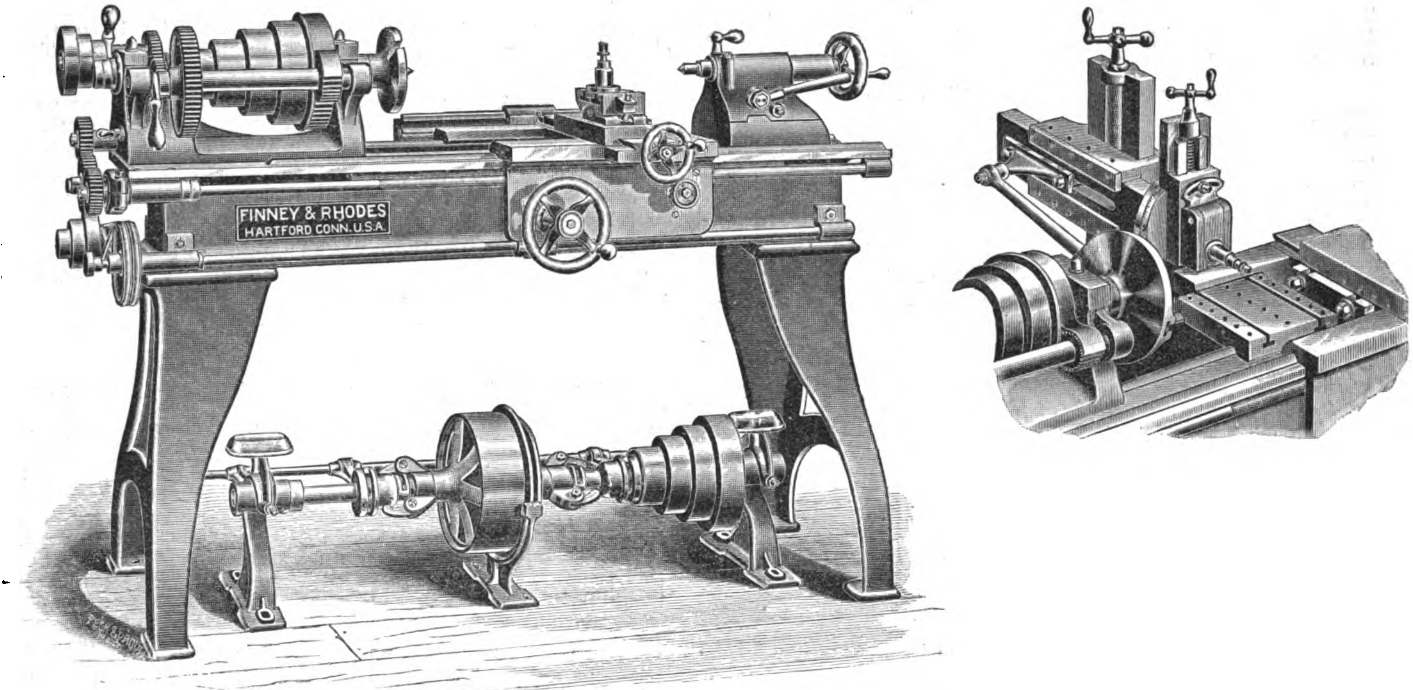
THE NEW 14-INCH GIBB LATHE.

THE value of a good lathe in electrical machine work is too well known to require further demonstration, and to produce a tool adapted to the largest variety of work, Messrs. Finney & Rhodes, of Hartford, Conn., have just brought out a new 14-inch Gibb lathe, illustrated in the accompanying engraving, Fig. 1.

The power gearing of this lathe is brought to the front of the head block instead of to the rear as usual. By this means the power is applied to the spindle downward and against the lifting tendency of the tool in the tool post, thereby largely reducing the tendency to "chatter."

Contrary to the impression that a lathe geared in this manner would interfere and be in the way of the operator, an inspection will show that this is not so. Being amply protected by a shield over the gearing at the face end of spindle it makes a clean lathe to work with as no oil or dirt can fly from the gearing or rub off on the clothes of the worker.

The feed mechanism is driven by small cone pulleys of three steps connecting with groove pulleys carrying straight and cross belts to the feed rod and is entirely independent of the screw and rocker gears which are only used for screw cutting. This feature will commend itself to all mechanics, as it is well known that the constant use of the rocker gearing for turning soon wears them so that they are unfit for good screw cutting. The worm of the feed rod runs in a reservoir of oil, especially provided, so that it is in no danger of cutting and running dry. The tool holder will commend itself at sight. It has the range and action of a weighted lathe carriage, and by the turn of a screw is clamped as though it were one solid piece, and no pressure or vibration can loosen or disturb it when either at its highest or lowest adjustment.



FIGS. 1 AND 2.—THE FINNEY & RHODES NEW 14-INCH GIBB LATHE.

The cross feed screw in the carriage is entirely covered and protected, passing through the centre of the lathe carriage in a direct line to the centre of the taper attachment to which it is connected by a sleeve. At the back of the lathe bed, is cast solid with the same a shelf nearly the full length of the bed, on which is swiveled the taper bar, the slide of which is fastened to the sleeve of the cross feed screw in such a manner that the pull and resistance are all in a straight line. Thus, when the taper bar is set at its greatest range, which is about two inches to the foot, in moving the lathe carriage by hand the resistance is barely felt by the operator.

A shaper attachment designed for this lathe, and shown in Fig. 2, is quite a novelty in this line and is made to fasten to the same table on which is the taper bar, and it receives its motion from a special face plate. It has a stroke of eight inches or less as wanted, thereby increasing the utility of the lathe, especially in small shops or experimental rooms, combining a lathe and shaper in one tool. It can be attached ready for work in less than five minutes.

Another special feature is the single-belt reversible countershaft, built for this lathe, and of novel construction. By the use of this counter, not only is space on the main line of shafting economized, but also the expense of belting and pulleys obviated. A lathe is much easier located if but one pulley is to be placed on the main line of shafting, especially in a crowded shop with interfering counters, than if spaces for two pulleys are necessary, as would be required with the common two-belted countershaft.

These are some of the main features of this lathe, which possesses many other points of excellence. It is a high grade lathe in workmanship, at a fair price.

APPARATUS OF THE CARPENTER ELECTRIC HEATING MANUFACTURING CO.

THE CARPENTER ELECTRIC HEATING MANUFACTURING CO. has been in operation for over a year with a large factory at St. Paul, Minn., engaged in the manufacture of devices of all kinds to be heated by electricity. These include cooking utensils, which are heated by conducting the current directly to the parts requiring the heat, and which lose almost nothing by radiation.

An example of this is the electric flatiron. The surface of this implement is put through a process which extracts from the metal all impurities. There is then spread on the surface an enamel, the composition of which is a secret, and in this is laid a plain iron wire zigzagged all over the surface, with the two ends extended half an inch apart up to within half an inch of the rear edge of the surface. A piece of copper wire is laid on the soft enamel from the rear edge, up to and connecting with each point of the iron wire. Then more enamel is spread on the surface, covering the wire completely.

The two copper points which are laid from the rear edge and connected with the ends of the iron wire are the terminals. The heat in the enamel can be easily regulated to the desired degree. The enamel containing the resistance wire and copper terminals is likewise laid on the inside surface of the pots and kettles, spiders, grid-irons, etc. The articles consume from ½ ampere to 10 amperes, according to their requirements, and being heated very quickly, are thereby able to complete any cooking operation in a very short time. Indeed a breakfast for a small family could be cooked in less than ten minutes from the time the switch is turned on.

MASSACHUSETTS ELECTRICAL ENGINEERING CO.

PLANS for a 700 light incandescent electric plant which will be immediately installed, have just been completed by the Massachusetts Electrical Engineering Company for the Merchants' Woolen Company, Dedham, Mass. The contract was awarded to the Westinghouse Electric Co.

The new town of Rumford Falls, Me., is to have a model electric lighting plant. Both arc and incandescent lights will be supplied from a central station situated by the upper falls, and running from the water power there obtainable. The station will have a capacity of about 200 h. p., only a part of which will be used at present. The work is in the hands of the Massachusetts Electrical Engineering Company.

WESTERN NOTES.

The Railway Equipment Company have leased an extensive factory at Mansfield, Ohio, where they manufacture the Ahearn electric heaters for street railway heaters, cooking utensils and all kinds of domestic heating. In addition to this work they will make a full line of their numerous street railway devices and apparatus. They hold a number of strong patents on numerous valuable specialties for railroad work, the demand for which has been so large that they have found it expedient to arrange for their manufacture on a large scale to meet the growing demand. Mr. W. R. Mason, president of the company, has one of the Ahearn hot water heaters in continual service in his private office in the Pullman Building, Chicago. This, he states, is for making herb tea, but a lingering aroma suggestive of "hot toddy" is noticeable. This he explains as coming over with that lake breeze which has full sway on the front windows of the office.

Electric Appliance Company.—Among some of the latest specialties on which the Electric Appliance Company have built up a nice trade is the C. S. flush face push switch. This is being largely used for fine residence and office work, and frequently mentioned in architects' specifications. Another is the combination branch block, which takes the place of eight ordinary branch blocks. It is made of one piece of porcelain with handsome polished hardwood cover, and is considered far ahead of the old plan of making a crude wooden box and lining it with asbestos. The Ries regulating socket is another specialty which was first handled in Chicago by the Electric Appliance Company, and has now become a standard stock article.

The Bain Electric Manufacturing Co., 49 South Jefferson street, Chicago, will shortly place on the market a new arc lamp with exceedingly simple and novel construction. which is very economical and gives a strong light and is not liable to derangement of any kind. Mr. Foree Bain of this company has recently built some special dynamos for direct coupling on shaft for operation by gas and gasoline engines. These are exceedingly handsome machines and do their work with great economy.

Wm. Hood & Co., 239 La Salle street, Chicago, managers of the Electric Manufacturing Co., Oconto, Wis., have recently made extensive improvements in their office and wareroom to handle the growing trade. A large stock of Brilliant incandescent lamps of all standard voltages and candle powers has been received, and judging from the shipments, business is rushing.

The Union Electric Works, Chicago, are very busily engaged manufacturing the Crowdus primary batteries. These cells are very small and compact for their output and develop full power until the solution is exhausted, when they can be replenished without trouble in a few minutes; special simplified arrangements having been effected for this purpose.

Becker Bros., electrical engineers and machinists, 39–43 West Washington street, Chicago, are handling repair work for all kinds of electric motors and dynamos. They also do business in general experimental work and build special electrical machinery to order. The firm is composed of Mr. C. J. Becker and Mr. O. E. Becker.

The Midland Electric Works are busy in electrical construction and repairing work. Their shop is at 224 East Washington street, Chicago, and is well equipped with tools for all kinds of special work. Mr. Ray Griggs is president of the company, and Mr. C. Samms, secretary and treasurer.

The Chicago Electric Manufacturing Co., 73–75 West Jackson street, are very busy on all kinds of special electrical manufacturing work. Mr. E. R. Crolius, who some time ago accepted the business management, is securing lots of work and running his shop overtime right along.

Mr. Thos. G. Creaghead, formerly of this city, is to be married to Miss Elizabeth Bailie this winter. Mr. Creaghead is at the head of the Creaghead Engineering Co., of Cincinnati, and is doing a large contracting business in building electrical plants in Cincinnati and vicinity.

The Electric Improvement Manufacturing Co. at their Chicago office No. 239 La Salle street, are exhibiting the Perfection electric light desk lamp. This is a very handsome and convenient device and makes the light adjustable for typewriter stand, desk or chair.

W. E. Reid & Co., 339 Rookery, Chicago, are securing a number of orders for the McEwen engines and boilers manufactured by the C. H. McEwen Co. of Ridgeway, Pa. They report that their engines are giving good satisfaction, and repeat sales are the order of the day.

The St. Louis Electrical Supply Co., 809 Locust street, St. Louis, are equipping the Arlington Hotel at Hot Springs complete with bell annunciators and an electric plant of 1,500 incandescents and some arcs.

Mr. C. E. Sargent, Chicago, manager of A. L. Ide & Son, engine manufacturers of Springfield, recently issued a list about a yard long of Ideal engines in use in Chicago. It is a monument to Mr. Sargent's ability as a hustler in the engine business.

The McGuire Manufacturing Co. have sold the Chicago City Railway Co. sixty-one of their improved scale trucks No. 19 F, for use on the lines that they are about to equip with electricity. A number of these trucks will run to the World's Fair.

The Electrical Construction Department of the Columbian Exposition are installing several additional dynamos in their temporary plant for supplying the current required for the extensive illuminations for the dedicatory ceremonies.

Mr. Coleman, of the Electric Specialty Co. of this city, has equipped an electrical carriage, the invention of R. W. O. Watt. This carriage is built with pneumatic tire bicycle wheels, is very light, and the operation is highly successful.

The Pioneer Armature Works, 195 to 199 South Canal street, are exhibiting some very handsome work on rewinding armatures. They handle armatures of all sizes and make a feature of doing firm and reliable work.

The Rice Machinery Co. are moving their office with a largely increased line of pulleys, hangers and power transmission machinery to more extensive quarters at No. 166 to 174 South Clinton street, Chicago.

The Standard Electric Co., 313–317 South Canal street, are closing numerous contracts for standard arc apparatus. Their plants, both arc and incandescent, are giving excellent satisfaction.

Mr. Thos. G. Grier, the well-known electrical engineer of Chicago, is engaged on some special work in connection with the installation of the lighting at the Fair grounds, Jackson Park.

G. E. Horn & Co. are having quite a run on the excellent line of bells they manufacture. They will shortly bring out other valuable electrical specialties.

Knapp Electrical Works have nothing to complain of, and their volume of orders is always on the increase. Safety wire is daily finding new friends.

CANADIAN NOTES.

A Montreal Suburban Railway.—The residents of the towns and villages on the opposite side of the St. Lawrence River to Montreal, have petitioned the Grand Trunk Railway to erect a light bridge structure, capable of accommodating wagons and an electric railway, on one side of the Victoria Bridge and supported upon its piers. Every fall and spring, owing to the state of the ice in the river, this district is absolutely cut off from communication with Montreal except by a railway which does not meet the requirements of local travel; consequently it is claimed that this scheme, in connection with a system of electric railways, would be a boon to the people and a profitable one to the capitalists undertaking it.

Electrical Inspection.—In reference to the system of electric light and meter inspection, which it is reported is to be established by the Dominion Government, the Department of Inland Revenue, which takes charge of such inspections, states that this matter is only under consideration and a bill being prepared, but, at present, the department is unable to give any information as to the scope of the act.

The Ahearn Electric Heating and Manufacturing Company, Limited, is applying for incorporation, with a capital of $250,000, and headquarters at Ottawa, Ont. The object of this company is to supply heat, light and power by electricity and also to manufacture and deal in electrical apparatus.

PHILADELPHIA NOTES.

Mr. William A. Famous, for several years connected with well-known electrical companies of this city, has been appointed Eastern sales agent for the Electric Manufacturing Co., of Oconto, Wis., with office and salesrooms at 103 Vine street. Mr. Famous is one of those untiring workers who with a good article—the "Brilliant" incandescent lamp for example—always meet with success.

Mr. Benj. W. Tingley, secretary of the Heisler Electric Co., is visiting St. Louis and several points in Texas in the interest of the company.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

THE
Electrical Engineer.

VOL. XIV. OCTOBER 19, 1892. No. 233.

THE first actual intimation that Columbus had, four hundred years ago, of the existence of the western world, was given him by the feeble glimmer of a distant light, and beyond doubt the first warning that the Caribs had of his fateful approach was afforded them by the dim poop lantern of his own ship. To-day, were Columbus again a European immigrant desirous to discover what manner of country this was, he would be likely on reaching our shores to be greeted first by the broad and cheerful electric beam from Liberty's lofty torch, and then to be gladdened by the airy span of arc lights that glitter between New York and Brooklyn.

During the past week, New York has been endeavoring in various ways and with the help of about four million inhabitants and visitors to do honor to the great and glorious memory of Columbus; and seems to have "celebrated" pretty successfully. The special festivities included a night parade, in which free use was made of electricity; and one of the most noteworthy of the decorative features was the extraordinary profusion of incandescent lights in set pieces, signs, tableaux and structural effects. It would be impossible to say how much money was spent on these designs of which there were literally hundreds all over the city, but the estimate has been made that they represented an expenditure of not less than $250,000, in which sum may be included a large quantity of special arc lighting and the use of a great many search lights in different parts of the city and along the water front. A few notes and sketches are here given of the more meritorious effects.

THE "OCEAN AND CABLE" FLOAT IN THE COLUMBUS NIGHT PARADE.

The Edison Building on Broad street was outlined with sixteen arc lights, eight running down each side, while over the cornice were the dates, "1492" and "1892" in large figures made of incandescent lamps. In the centre of the building were three rows of the electric revolving wheels used in Washington during the recent Grand Army celebration. These had each some conventional design in lamps and, constantly moving and changing as they did, produced a very brilliant effect. On the roof was mounted a search light that played incessantly over the city and the throngs in the streets.

BROOKLYN BRIDGE:—ARC LIGHT, SEARCH LIGHTS, FIREWORKS.

The building of the New York Life Insurance Company was profusely decorated and lavishly illuminated by means of no fewer than 1,080 incandescent lamps. The arrangement of the lights is clearly shown in the illustration. The letters and the dates, 1492 and 1892, were composed of gold-colored lamps, while bands of red, white and blue lamps extended across the entire façade. The colossal portrait of Columbus over the entrance, was framed by 54 white and gold lamps, and the shield was similarly lighted. Current was taken from the isolated plant consisting of three Thomson-Houston generators with a combined capacity of 1,250 lights, driven by two Watts-Campbell Corliss engines. This is used ordinarily to light the entire building. The current was controlled by Johnson switches on each floor and the wiring was such that the rows of letters and borders were divided into halves, each having an independent switch. It is interesting to note that, so carefully was all this temporary work done that there was not so much as a flicker in the entire system, and the engine ran as though furnishing power to an old circuit from which the "kinks" had been thoroughly removed.

The immense store of Bloomingdale Bros., at the corner of East Fifty-ninth street and Third avenue, was illuminated from roof to sidewalk. The main show window on the ground floor represented the Hall of Audience at the Spanish Court what time the future discoverer unfolded his plans to their Most Catholic Majesties. A background of stained glass set off the wax figures, and behind this were arranged the lights, shedding a soft, though brilliant glow upon the rich costumes and decorations.

Outside the building on the second, third and fourth stories were 14 American shields each composed of twenty 16 c. p. lamps, the current for which was taken from the mains on their respective floors, while the whole was surmounted by the legend "1492, Columbus, 1892" composed of characters eight feet in height, each marked out with 30 colored lamps. In front of the main entrance of the building was a large painting of the landing of Columbus, set with a red background, and the frame enclosed by a border of about 100 lights. Each letter and shield had a separate Bryant cut-out on a lightning arrester. The arc lights about the store were all removed for the occasion lest the harmony of the decorative effect should be marred.

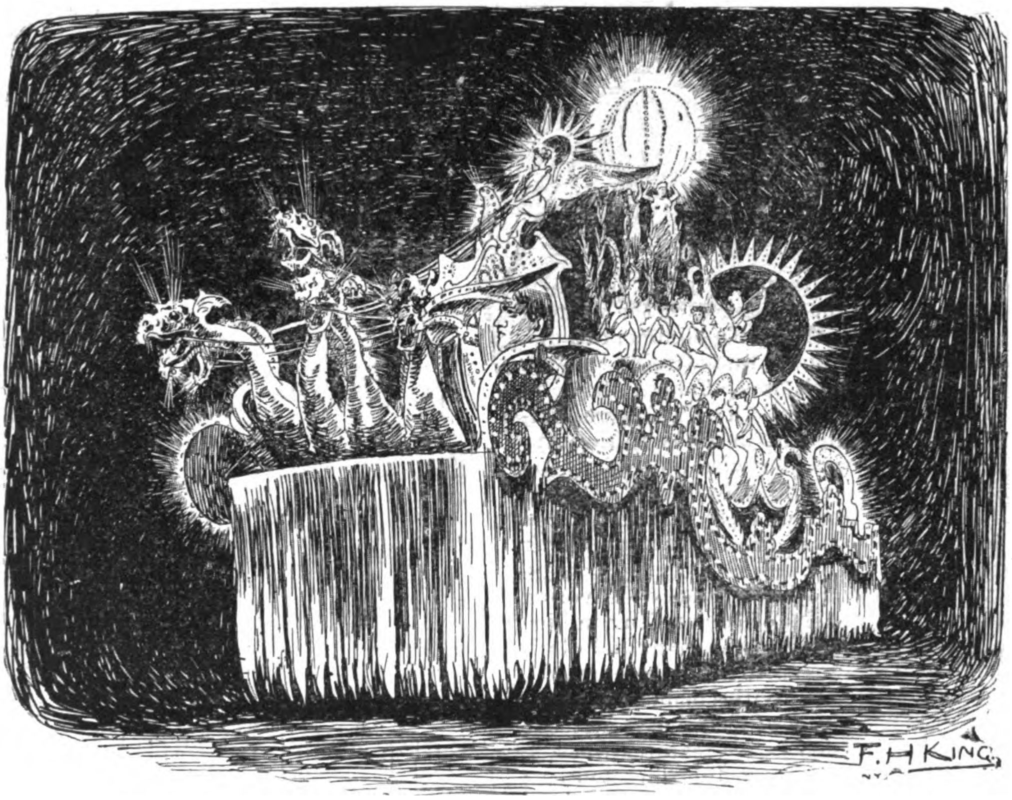
Ehrich Bros., the dry goods merchants, corner Sixth avenue and Twenty-third street, had a very attractive decoration. On the Sixth avenue side were 15 rows of red, white and blue bunting with corresponding incandescent colored lights. These rows ran from the roof coming together at the head of the main entrance, at which place was a fac-simile in painted wood of their trade-mark, 18 feet long and 13 feet wide. It consists of a lion holding in its forepaws a shield with the monogram "E. B." The E. was made of red lights, and the B. of blue. The outline of the lion was in white lights. There were 150 incandescent lamps in this one piece.

At the Union League Club on the northeast corner of Fifth avenue and Thirty-ninth street a beautiful effect was produced by placing rows of red, white and blue lamps upon wide cloth strips, or bars, running vertically the entire height of the building between the windows. There were seven of these panels on the avenue front.

The Metropolitan Hotel at Spring street and Broadway had over the main entrance a large painting, representing the landing of Columbus, surrounded by 48 incandescent lamps. The absence of other decoration, thus concentrating the brilliant colors in the picture itself, produced a very striking effect. Near the Metropolitan, on Niblo's Theatre portico, a search light was perched which did remarkable execution as it flashed up and down the brilliantly decorated thoroughfare and revealed the great tide of humanity flowing between the solid banks of brick and stone mile after mile.

Undoubtedly the most brilliant of the floats in the night procession was the car, "Electra," designed and equipped by the General Electric Company, and well represented in the illustration herewith. It was intended to show Edison's triumph over the Hydra of Darkness, or something of that kind. There were, altogether, on this one float 3,500 incandescent lamps, taking their current from accumulators furnished by the Union Electric Company. and charged from a dynamo of the General Electric Company at their office building on Broad street. These batteries weighed about three tons and added greatly to the stability of the car. Unfortunately the "float" had little of the lightness that the word suggests, being entirely without springs, so that both the lamps and batteries—to say nothing of the human fairies—suffered terribly in their long journey uptown. In the lower part of the city, however, all the effects were seen in their full splendor, and the fairies were still sprightly and unbruised enough to smile on the crowd.

Another float deserving of mention was that entitled "The Ocean and the Cable," in which a tribute was paid to Cyrus Field, the man of whom it was strikingly said that he had moored the New World alongside the Old and thus completed the work of his forerunner, Columbus.



THE CAR "ELECTRA" IN THE COLUMBUS NIGHT PARADE, WITH 3,500 SMALL LAMPS.

The float showed an ocean steamer and two submarine cables dipping under the sea from shore to shore.

That dreadful architectural giraffe, the World Building, presented, for once, an imposing appearance. The immense dome was encircled at its base by a band of white lights, while alternate lines of red, white and blue lights following the ribbed lines, extended to the lantern. More than 200 Edison lamps of 32 c. p. were used, and Mr. F. Shede, the electrician of the World Publishing Company, worked for seven days at an elevation of 300 feet above the ground to complete the work. The wiring was incased in copper-covered Interior Conduit Company's tubing of special make.

Altogether the electric display of the week was a brilliant success. In some respects it might have been much improved upon, and Chicago will doubtless profit next year by New York's triumphs and failures in this field. At any rate it was fitting and appropriate that the electric light should have been thus freely resorted to during the celebration as one of the distinctive advances made by the modern spirit of invention and investigation of which, through all time, Columbus will remain one of the grandest exemplars.

Some Electrical Effects Displayed During Columbus Week.

A NEW USE FOR THE TELEPHONE.

A novel scheme has lately been perfected at the military post, Fort Sheridan, Ill., for use at the rifle range, for the general Government shooting contests, which began the 26th ult. At each of the firing points on the range, the most distant one being 1,200 yards, are located boxes flush with the surface of the earth. In each of these boxes is a spring jack connecting with an underground lead-encased conductor leading to the range house, where all shots are recorded, and also to the targets. When firing is going on from any of these points, a telephone mounted on a tripod is plugged into the nearest box by means of a split plug and flexible cord, establishing immediate communication with the targets, thus giving the scores correctly after each shot. This installation is due to the ingenuity of Capt. Allen, of the Signal Department U. S. A., and E. M. Hatheway, the consulting electrical engineer, of Chicago.

INVENTION AND THE DISCOVERY OF AMERICA.

BY

Edward P. Thompson

While the whole world is honoring the Italian, Christopher Columbus, the electrician should bring forward prominently the name of the importer of the invention of the mariner's compass, Marco Polo, also an Italian, who was the first reported European who saw China, and who discovered Japan, which was not even suspected as being in existence. He and his father were great travelers and discoverers, and their maps and descriptions were noted for accuracy. They were the means of stimulating Columbus in his project, so that in this way, also, Marco Polo was an indirect assistant in the discovery of the New World. Since the importation of the invention, the Chinese have claimed that the property of the lodestone to point north was known to them as early as 2634 B. C., and was used in navigation in the year 300 A. D. Its introduction into Italy was not long before the time of Columbus. It is not known as an absolute fact that Polo was the importer, but there is strong evidence in his favor. One account gives Flavio Gioja the credit of being the inventor, original as far as Europe is concerned; but no evidence is produced. As to the prior Chinese inventor, he must be honored as anonymous.

In conclusion, let us also remember Columbus, not only as a geographical discoverer, but also as a scientific investigator, for it is he who first discovered and partially formulated the law of variation of the magnetic needle during his trans-Atlantic trip.

The unexpected deviations caused the sailors to become discontented and almost violent, because they believed the needle was losing its mysterious power of pointing toward the north star, but Columbus reassured them by explaining his theory of the action.

Prof. J. P. Barrett, chief of department of electricity, of the World's Columbian Exposition, is now in the East rounding up Eastern exhibitors for the Exposition and talking over space thereat, and incidentally attending the dedicatory ceremonies in New York. One of the special objects of Prof. Barrett's visit is to discuss with Mr. Edison the various details and particulars of his exhibit at the Fair.

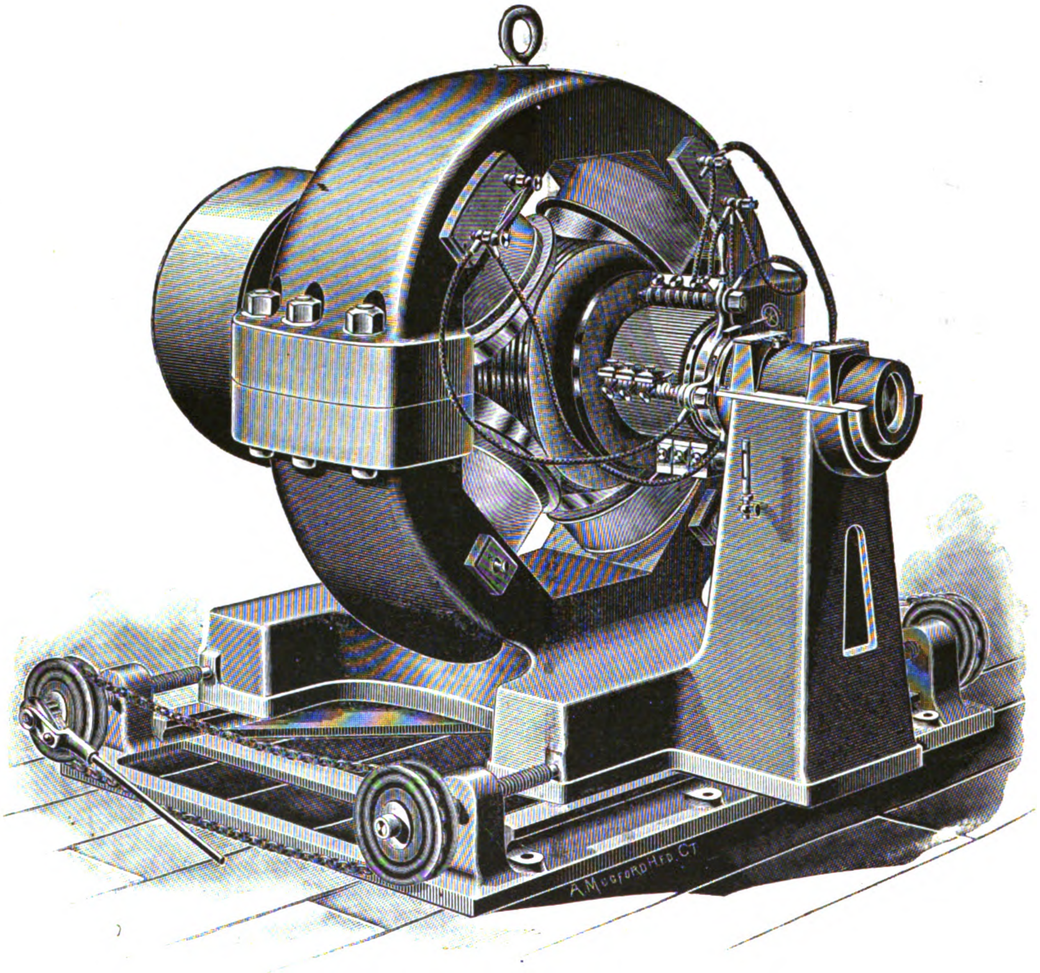
ELECTRIC RAILWAY DEPARTMENT.

THE MATHER GENERATOR FOR ELECTRIC RAILWAY WORK.

BY

Wm. A. Anthony.

The special feature of the dynamos manufactured by the Mather Electric Company, of Manchester, Conn., has been the construction of field magnets without joints, and having a general form as nearly as possible like the natural one of the lines of magnetic force. Following out this principle of construction, the Mather incandescent dynamos, which have been on the market for several years, have been made with cast iron field magnets of the well-known ring form, composed of one piece, and carrying the armature by means of yokes supported by steel bars passing through the poles of the magnets.



A. MUGFORD HFD. CT.

MATHER GENERATOR FOR ELECTRIC RAILWAY WORK.

This form serves a most excellent purpose for incandescent dynamos, and although it seems to those who are not familiar with the mode of winding a difficult form to wind, it is really not so, when wound for low potentials. But for high potential machines it becomes necessary, in order to avoid the strain on the field coils due to sudden changes of potential or breaking of the field circuit, to wind the wires in such a way that no two wires having any considerable difference of potential should be near each other. This necessitated the adoption of a form of field coil that could be wound in a lathe, with a single wire, in layers, and it was this necessity that led to the adoption of the form of generators and motors here illustrated. It was deemed very desirable to retain as far as possible the special features of the incandescent machines, and to this end designs were made to cast the field magnets in one piece, or, if joints are used at all, they are made by a cylindrical piece fitting into a hole bored in the casting and presenting a very large surface of contact so as to reduce as far as possible the magnetic resistance of the joints; and the machine has been so constructed that there are exactly the same joints in each of the magnetic circuits. By this construction there is obtained a perfect symmetry of form in the several magnetic circuits of any one field magnet, and the different coils of the armature all pass through precisely equal magnetic fields. As a result of this arrangement, there is absolute freedom from sparking at the commutator. In the four-pole machines, the armatures are so wound that there are only two paths for the current, but, at the same time, the winding is such, and the commutator so constructed, that opposite bars are joined by a cross-connection, and either two or four brushes can be used at pleasure.

The speeds of the various machines have been adjusted to the sizes of the armatures. The faster a generator or a motor runs, the greater is the output to be obtained, and the limit of speed is entirely a mechanical one. In designing these machines, it has been the aim of the Mather Company to use as high a speed as is consistent with good mechanical principles, and they believe that the speeds adopted will be found in every way more satisfactory than anything slower. Besides the advantage of greater output, the smaller number of windings upon the armature running at a higher speed presents very many advantages in smooth running at the commutator.

A very important factor in the construction of large machines is the quality of the sheet iron of which the armatures are made. Upon this the Mather Company have made a great number of experiments, testing all their iron in various ways, but especially by building up armature cores of half of one kind of iron and half of another, and running these armature cores, before they were wound, in an excited field. This tests the iron under exactly the conditions to which it is exposed in practice, and if one end of the core was found to heat more than the other, the iron which heated less was, of course, the better iron. By such experiments as this the Mather Company have at last found an iron which can be used for armature cores of 24 and 30 inches diameter, running in intense fields, and at speeds of 400 or 500 revolutions, with very little heating. This reduces the unknown losses in the running of the dynamo to a minimum, and the $C^2 R$ losses in the winding of the armature and field, which can be known to a fraction, become the greater part of the total loss when the machine is doing work.

The Mather Company claim a machine in which all the magnetic and electrical parts are absolutely balanced, a machine which will run at a perfectly safe and manageable speed, and gives a large output for its weight; which runs with absolute freedom from sparking at the commutator under great variations of load, and has an efficiency at least as high as, if not higher than, any other similar machine in the market. The sizes of machines constructed for railway generators are 50, 75, 120, 180 and 225 kilowatts capacity. The last has six poles; the others are four-pole machines. The same principles of construction apply to all.

THE ELEVATED ELECTRIC ROAD FOR LIVERPOOL.

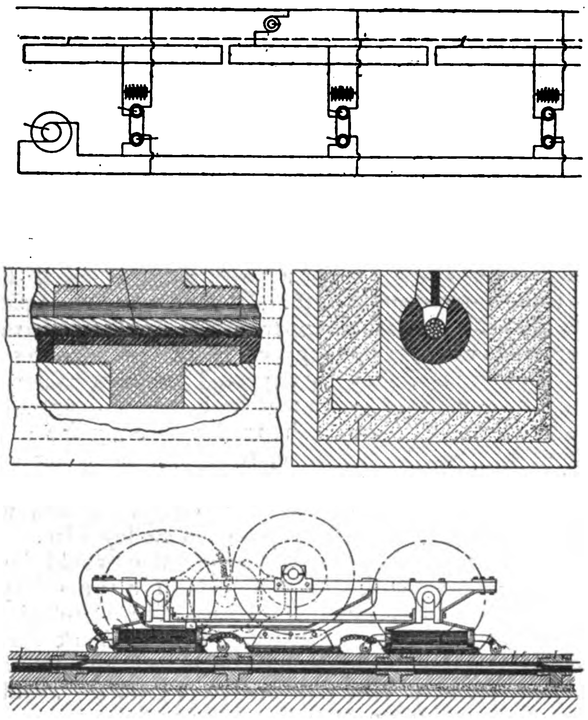
We have already published some details about the elevated electric road which Liverpool is soon to have, running parallel with the docks a distance of about six miles, with sixteen stations very much after the New York model. It is to be worked by electricity, generated at a power house about the middle of the line. At this station are four engines, each capable of working up to 400 indicated horse power, and each driving an Elwell-Parker dynamo. The current will be carried by a steel conductor, placed on porcelain insulators, supported upon cross-timbers between the rails of each track. Hinged collectors of cast iron, sliding upon this conductor, will make the connection. The motors are not placed upon a separate locomotive, but are carried by the passenger carriages.

Two carriages, each seating fifty-six passengers and provided with a motor at one end, will constitute a train. The carriages are to be so coupled as to give a motor at each end of the train, and the motors will be so connected together as to be controlled from either end by the driver, who will always change ends upon arrival at a terminus. The driver will carry a key, without which the motor cannot be operated. All the carriages will be alike, but they will contain compartments for two classes of passengers. A train loaded with passengers will weigh about forty tons. The carriages will be lighted by electricity and fitted with the Westinghouse brake. The total cost of this railway, including equipment, will not exceed $425,000 a mile.

THE RIKER CLOSED CONDUIT RAILWAY SYSTEM.

The main difficulty encountered in the attempt to use underground systems is attendant on the use of an open conduit, and many efforts have been made to overcome this disadvantage.

It has been proposed to carry the service conductor in a conduit closed from end to end and to make electrical connection between the same and an external conductor by lifting *seriatim* a series of pivoted contact-pieces, the lifting of these contacts being effected by means of magnets carried by the car, and also to inclose the conductor in a conduit above which is a magnetic rail, which, when magnetized, inductively lifts the conductor into contact and allows it to drop by gravity after the car has passed.



Figs. 1, 2 and 3.—Riker Closed Conduit Railway System.

Mr. Andrew L. Riker, of this city, has recently devised a system in which the working conductor is loosely laid in a tube made wholly or in part of magnetic material. It is, however, in its position of rest or non-action, electrically insulated from the tube, by lining the bottom of the tube with insulating material. The upper surface of the conduit is exposed above or about flush with the ground between the two rails. The poles of the lifting magnet are arranged to make contact with the surface of the conduit, and thus to magnetize the latter. The poles of the magnets may be in the form of brushes, making a sliding contact with the magnetic tube or in the form of wheels to roll thereon. Under the influence of the magnets that part of the inclosed conductor which lies beneath them is attracted to the top of the conduit, and thus makes electrical contact, falling back again when the car has passed. It is of course necessary that the conductor or cable be composed of iron wires or have an iron core, so that it may respond to the attraction of the magnets. The surface of the magnetic tube is galvanized for the purpose of preventing rust and also to prevent the conductor from sticking to the top of the conduit.

GUARD WIRES FOR ELECTRIC RAILWAYS.

BY

Frank B. Rae

In the construction of trolley lines for electric street railways it has become the practice to erect parallel wires immediately above the trolley lines for the purpose of catching and preventing telephone, telegraph and other bare conductors, which might fall, from coming in contact with the trolley line. These guard wires are usually placed upon span wires attached to the trolley line poles about 10 to 12 inches above the span wires carrying the trolley lines. The guard span wires are usually insulated from the pole and are threaded upon the ordinary porcelain insulator, upon which the guard wire rests or is suspended, and is thus insulated from the span wires.

These guard wires are erected, as a rule, only where foreign wires cross the trolley line, or in the centre of the town where other lines may be strung across the railway conductors. They do not usually form a complete system, nor are they connected electrically with the power station. There is, therefore, no provision for determining whether the guard wires have not accidentally become electrically connected with the trolley line, or with some other wire of even higher potential, and that they offer any real protection to foreign wires or to the apparatus at the end of them seems to be a question of faith. In addition to the protection to the railway station apparatus, or to the apparatus of telephone or other company which the guard wires are supposed to furnish, they are expected to protect persons or animals from shock by contact with the hanging end of a broken wire, held clear of the trolley lines by the guard wires; or to protect telephone, telegraph or other companies' wiremen in stringing wires across the railway circuit. Under such circumstances a charged guard wire would be even more dangerous than the trolley wire.

It would seem that the better practice would be to ground the guard wires, and to depend for the safety of apparatus upon limit switches or fuse wires at telephone, telegraph and other centres of distribution. Workmen engaged in stringing wires would be careful to keep their work clear of guard wires known to be grounded, and in event of their making contact by their work between the grounded guard wire and the trolley line, that portion of wire making such contact would be burned in two; or, if the wire was sufficiently large, the street railway limit switch would operate; but the better ground offered by the guard wire would protect the workmen. If it is thought that the grounded guard wire presents any danger to workmen upon the trolley line, the guard wires could be divided into sections and readily disconnected from the ground upon the section where repairs to the trolley line might be necessary.

It would seem, too, that the grounding of the guard wires would offer protection from lightning by providing a continuous lightning arrester where it would be most effective, and that this latter consideration is, perhaps, the best argument to advance in favor of grounding guard wires. Some 14 years ago, while engaged with the Western Union Telegraph Company as electrician for the Pacific coast division, great trouble was experienced in the operation of wires across the plains by reason of the static charge upon the lines. This difficulty was almost entirely overcome by using one of the wires as a ground wire, making frequent connection with an earth plate at the base of the poles. The so-called static effect upon overhead wires increases with their distance from the earth; it follows that if the earth can be placed near the line, the static effect would be decreased, and this is practically accomplished in electric railway construction by grounding the guard wires.

THE COMPARATIVE EFFICIENCY OF THE COMMUTATED FIELD AND THE EXTERNAL RESISTANCE FOR CONTROLLING RAILWAY SWITCHES.

BY

Harold P. Wellman.

I was surprised, upon reading Mr. Thorburn Reid's article upon the above subject,[1] that he should presume to decide so important a question, as the comparison of the most general and successful methods of railway motor control, with so little and so weak argument. And after carefully reading this article, I can find no comparison of the two methods.

Mr. Reid's argument can be summed up as follows: He assumes a motor having a certain resistance in circuit, and by doubling the number of field turns he increases the field strength by 20 per cent., thus decreasing the speed. And now, from the fact that he can get back to the original speed by decreasing the resistance, and that the current necessary with the increased field is less to produce the required torque, he concludes that he has decreased the loss and demonstrated the higher efficiency of the commutated field. That the resistance necessary to restore the speed and complete this questionable cycle *is less*, is an argument in favor of external resistance, *i. e.*, we should use an intense field.

This reasoning of Mr. Reid also only applies to decreasing the speed, and how he would argue for an increasing speed, I dare not speculate on; but the same reasoning would give an increase of current and resistance together with a weakened field.

This would increase the $C^2 R$ loss, and prove its inefficiency for high speeds, which is another point for the external resistance; for if by increasing the field the efficiency is increased, as shown by Mr. Reid, then as there cannot be two points of maximum economy, the only way to reach it is by maximum field strength, *i. e.*, that used with external resistance.

Assume as Mr. Reid did, two motors with the turns in field, speed, current, and resistance in circuit the same, this latter being made by the resistance of field coils in one case and the resistance of field coils plus the external resistance in the other. Now, in order to increase the speed, we, for instance, reduce the distance in circuit to one-half. Then the motor with the external resistance will increase its speed and decrease the loss to $C^2 \frac{R}{2}$ While with the motor with the commutated field the same change in resistance would give a corresponding increase in speed; but it also gives a weakened field requiring an increased current, $c_1 = c\, n$, (n being a factor depending upon the saturation, but always greater than unity). Thus leaving the loss, $c^2\, n\, \frac{R}{2}$, which is of course greater than the loss by external resistance, which was $c^2\, \frac{R}{2}$.

Therefore I claim that the method of control by external resistance is the more efficient, which is the reverse of the stand taken by Mr. Reid.

And again, while the commutated field *does* give a varying current, this current can never be *less* than required with external resistance, but will be *equal* to it only at minimum speed and maximum field as used with external resistance. Hence the line loss is *greater* and the plant efficiency *less* than claimed by Mr. Reid.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 208 *Broadway, New York City.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XIV. NEW YORK, OCTOBER 19, 1892. No. 233.

The electric motor of to-day represents a great advance over the electric motor of last year.—John N. Beckley.

THE ADVANCE OF THE ELECTRIC RAILWAY.

PERHAPS it would be hardly going too far to say that the convention this week in Cleveland is an electrical one. It is true that the American Street Railway Association contains in its large and influential membership a good many important cable and horse railroads. It is equally true that the officers of the Association do all that they can to secure a discussion of all the questions that pertain to street railway construction and operation. But the logic of events is altogether on the side of electric traction, and the most hurried glance at the programme reveals the fact that the subjects which interest the majority of street railway men when in convention assembled are those that deal with electricity.

As a matter of statistics it would appear that electricity is running about 500 street railways in the United States and Canada, a gain of nearly 200 in two years, and fully equal to half of the total street railway system of America. The investment in these roads has passed the $200,000,000 mark, but gives no sign of falling off to a lower rate of increase, for it was only in February, 1891, that the investment was estimated at $50,000,000. These roads are operating at least 12,000 cars, or two to every mile of track. These are wonderful figures of growth since the time when the present writer compiled in 1887 the first American electric railway statistics and could present only the slim total of thirteen roads, some of which were in reality mere experimental stretches of track with but a couple of cars on them.

Such figures as those just cited as giving the status of the industry to-day are in themselves the only vindication that is necessary for the much-abused trolley. They are practically trolley figures, for conduit roads do not exist in this country, and storage battery cars may be counted on the fingers of two hands. Let the trolley, then, have its due meed of praise and credit.

But it is at such seasons as this that one may well inquire as to the trend of things. Is it to be all trolley and always trolley? Hardly. The conduit road is much nearer commercial perfection than it ever was before, and the storage car to-day has reached the point where it can be run by anybody willing to foot the bills. There are, moreover, in the field to-day storage battery systems that have in them so many elements of higher economy and advantage that, in view of the public clamor for them, it is difficult to see how they can be kept back from general adoption.

There are other fields that electric traction is beginning to occupy which are legitimately within the field of discussion of the Cleveland convention, although no provision has been made for them on the programme. The industry has made three new departures quite recently. It has annexed the domain of underground passenger traction in London; it has attacked the problems of elevated railway work in Kansas City, Baltimore and Liverpool, and in more than one American State it has measured itself against the steam railroad for cross-country work. Either of these departments is large enough for all the talent and money and energy now available, while combined they present opportunities the like of which have never before been seen in electrical application.

THE LAMP DECISION.

LAMP manufacturers, lighting companies and consumers are looking forward with much interest and, in some cases, in our judgment, with undue apprehension, to the adoption of a general policy by the General Electric Company in respect to its legal rights under the decision of the United States Appellate Court sustaining the Edison incandescent lamp patent.

Neither alarm nor apprehension seems warranted by the present state of the case. In September, 1886, THE ELECTRICAL ENGINEER said:

> At present there is apparently not sufficient control of fundamental features of arc or incandescent lamps, or of dynamos, by virtue of patented inventions to justify any material taxation of the business of lighting, in the way of royalty.

Since then three considerable electrical patents in the domain of lighting have been sustained by the courts—the Thomson regulator patent, the Brush double-carbon patent and the Edison incandescent lamp patent. Neither of the first two seems to have hampered seriously the production of satisfactory dynamos and arc lamps by companies and firms outside of their protection; and although the Edison decision is more comprehensive in its scope, we have sufficient confidence in the ingenuity and sagacity of American inventors and leaders in electrical industry to believe that even a drastic policy on the part of the General Electric Company could not, for any considerable period of time, prevent the manufacture, sale and use of incandescent lamps.

But a much more gratifying element in the situation lies in the fact that there are good reasons for believing that after due consideration the General Company will find it more profitable, and therefore more expedient, to adopt a general policy of moderation and conciliation than to try to enforce peremptory measures against infringers. Under the decision of the court there can be no doubt of their right to prosecute infringers of the second claim of the Edison patent; but the situation is so complex that such a policy, over the whole field, is hardly to be expected. The pre-existing contract relations of the Edison and Thomson-Houston companies with local lighting companies alone constitute a serious obstacle to any summary stoppage of the supply of lamps to such operating companies as are not using the authorized lamps. Moreover, the capacity of the lamp works controlled by the General Company is not sufficient to supply the entire demand. It will surely not benefit the company to reduce the supply below the wants of the public.

A further circumstance indicating a policy of moderation on the part of the General Electric Company is to be found in the probably short period remaining to the patent. It is thought, in view of decisions in similar cases, under section 4887 of the Revised Statutes, that the Edison patent will expire November 10, 1893, the date at which the English patent for the same invention will terminate. Under the incentive of the patent alone, if so short lived, the owners of it would hardly deem it a good investment to expand their lamp works to a capacity adequate to supplying the entire demand of the country.

Many lamp makers will find some hopeful indication of their immunity from serious penalty for past infringement in the remark reported of Judge Wallace, July 23, 1891, during the hearing of counsel for the Edison Company and the United States Company in the matter of settling the terms of the decree upon the decision of July 14.

> "His Honor said he thought that the greatest cloud that hung over the patent was in its claims—in the language of the patent itself. He did not much blame any infringer for assuming that he could go on and make any sort of an incandescent lamp without fear of that patent."

On the whole, it would seem that the General Company would best subserve its own interests and that of the public by establishing so moderate a license fee or royalty as to enable all reputable makers of good lamps to continue their business, and by so regulating prices as to preclude temptation to the production of inferior lamps.

STEINMETZ ON THE LAW OF HYSTERESIS.

In last week's issue we printed an abstract of Mr. Chas. P. Steinmetz's paper read before the American Institute of Electrical Engineers. This paper, viewed from a purely scientific standpoint, may be considered to be probably the most important which has been presented to that body of late years. In his previous work on this subject Mr. Steinmetz had already given a glimpse of the direction in which he was working, and in the present paper he has practically accomplished for the magnetic circuit what Ohm did for the electric. Ohm's law represents the energy function of electric circuits, by giving the loss of energy in an electric conductor as a function of the electric quantities. In an analogous way Steinmetz's law of hysteresis gives the energy function of the magnetic circuit in its most general form, showing the energy consumption to be independent of the absolute values of magnetization, and only determined by the amplitude of the magnetic variation, being proportional to the 1.6th power thereof, with a coefficient of proportionality η.

But the importance of Mr. Steinmetz's latest work is still further enhanced by the reduction and explanation of all the various phenomena of the magnetic circuit by the aid of only three constants, namely, α, the coefficient of magnetic hardness; σ, the coefficient of magnetic saturation, and η, the coefficient of magnetic hysteresis. He thus finally brings the magnetic circuit within the reach of analytical treatment, in the same way that the electric circuit has been mastered by Ohm's law.

Besides the demonstration of the law above mentioned, the paper is noteworthy on account of the very exhaustive treatise which it embodies on all the different magnetic materials, extending from sheet iron over the entire range to magnetite and even amalgam of iron. Besides this, we are given valuable information on the various methods of observation employed, on the phenomena of alternating and pulsating magnetism, on the theory of demagnetizing by means of alternating currents, etc.

In Mr. Steinmetz's paper we also find the first exact definition of the looped curve of hysteresis, namely, the energy expended by the magnetomotive force during the variation of magnetism. Ample proof is also presented that the assumption that this looped curve represents the energy wasted in the iron by molecular friction is erroneous, and that under certain conditions this loop may represent much more or much less energy than that expended by molecular friction. Mr. Steinmetz also points out an apparent error in the fundamental equations of Ewing's theory of molecular magnets, and gives the correct equations of equilibrium of molecular magnets, which show that the fundamental equations of magnetism are closely dependent upon the law of probability of molecular distances. He thus holds out to us the hope of our obtaining a full understanding of the phenomenon of magnetism in the near future. A full appreciation of the value of Mr. Steinmetz's paper, covering 109 pages of the Institute's *Transactions*, can indeed hardly be obtained without a close study of it.

The Westinghouse Electric Industry.

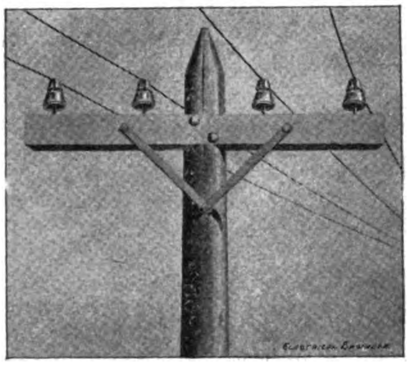
A LARGE portion of our space is devoted this week to an article descriptive of the great electrical industry that has been built up at Pittsburgh under Westinghouse auspices during the past six years. The record and exhibit are interesting in many ways, and are entirely creditable to those who have been associated with the creation and development of this great enterprise. It is curious that a company which came so late into the lighting field should have found so vast an area untouched, as it did, in the alternating system; and, be the revolutions of time what they may, Mr. Westinghouse is entitled to the praise due an electrical pioneer for his foresight in this direction. As much may be said for his quick appreciation of the work of Nikola Tesla, his energy in developing and perfecting electric railway apparatus, and his advanced position in regard to the long-distance transmission of electric power.

A Visit to the Westinghouse Electric Works at Pittsburgh.

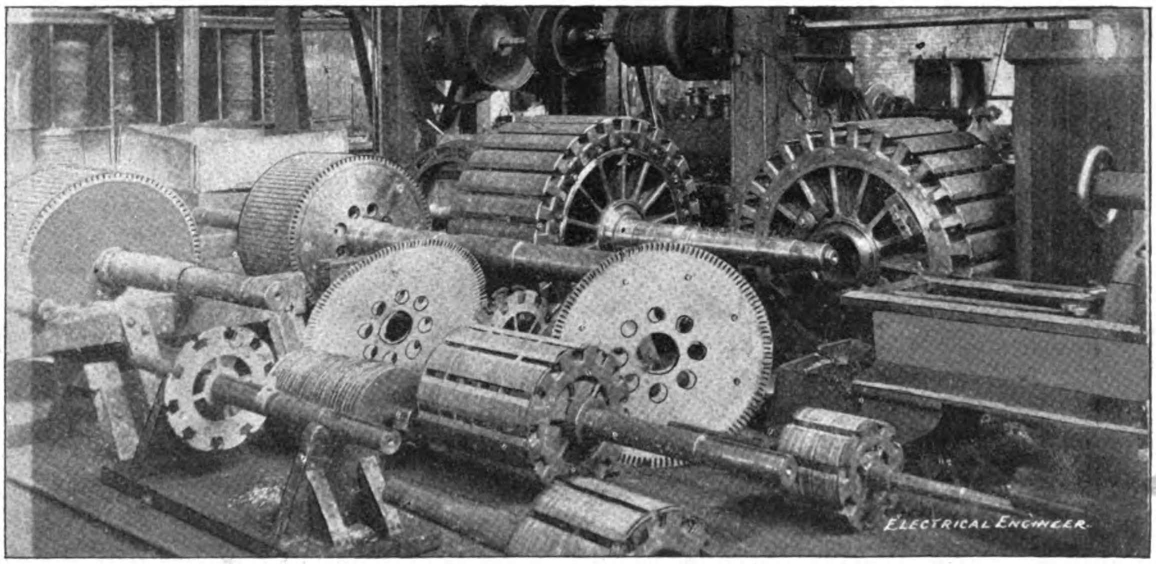
By

Jos. Wetzler.

I.



THE organization of the Westinghouse Electric Company in 1886, laid the foundation for an industry of which until that time very little was known either in the city of Pittsburgh or, for that matter, even in the United States. Until the Westinghouse Company entered the field of electrical manufacture, the direct-current system of incandescent electric lighting was the only method generally practiced. Owing to the many inherent disadvantages and limitations of that system for covering large areas, the introduction of incandescent lights had been very slow, and it may be truly stated that it is in no small measure due to the energetic efforts of the Westinghouse Company and the wonderful success of their alternating system that America is now the great electric country of the world. Previous to the introduction of the Westinghouse electric lighting system, incandescent plants were few and far between.



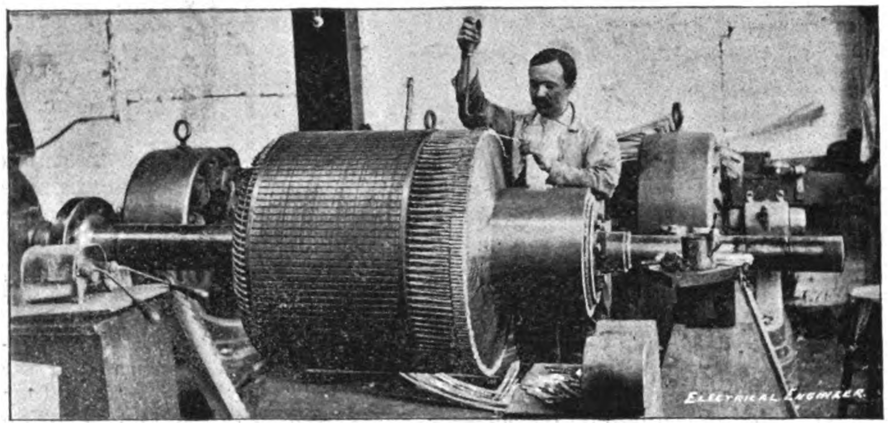
ALTERNATING AND DIRECT CURRENT ARMATURE CORES—WESTINGHOUSE WORKS, PITTSBURGH.

It was a very costly undertaking to establish a large central station and equip it with direct current apparatus having sufficient capacity and range to cover a city or town. Hence the incandescent light was, until 1886, only used by rich corporations, or in municipalities where thickly-populated districts warranted the establishment of a plant. Immediately upon the advent of the alternating system, electric lighting was brought within the reach of everybody in small and large towns, due to the fact that the current can by that system be carried a long distance without the expense of the heavier and more expensive copper wire needed for the direct current.

A demand was therefore at once created for the establishment of central station electric lighting plants such as had not been known before. Thus it came about that within four years the Westinghouse Company installed its apparatus in nearly four hundred cities and towns all over the world, and at this writing there are every night more than a million incandescent lamps burning throughout the world which obtain their current from Westinghouse alternating current generators—apparatus that has all been manufactured in the city of Pittsburgh. It can be readily seen, therefore, that through the Westinghouse Electric Company an influence has been exercised over one of the most important industries in this country, the results of which are of the utmost benefit and value to the whole industry.

As has already been stated, this company was organized is 1886. It grew out of a department of the Union Switch and Signal Company. The new corporation was capitalized with the sum of $5,000,000 and started to work. The company installed its first central station plant in Buffalo, N. Y., and for some time this was the focus of interest for the electrical public of that period. The successful operation of the Buffalo plant established the fact that an electrical system for the distribution of incandescent lighting had been put upon the market which had no equal for central station plants, intended to serve large areas.

Another feature of the Westinghouse system, and one which greatly enhanced its popularity, consisted in the excellence of the apparatus. Simplicity and durability of construction, with the highest efficiency, are made the paramount considerations in the manufacture of one and all of the apparatus of the Westinghouse Electric Company. The result has been that the reputation of the system soon grew worldwide. Demands for its apparatus came, within the first year after the establishment of the company, from England, China, Japan, the West Indies and other foreign countries. One of the Westinghouse plants in England is situated in the heart of London and has a capacity of 50,000 incandescent lamps.



ELECTRICAL ENGINEER.

Soldering Armature Wires to Commutator of Railway Generator.

In 1888 the company made another great step in the further development of its system by the introduction of devices for measuring the electric current as consumed by the lamps. This device is the Shallenberger alternating current meter, the commercial advantages of which appealed at once to every central station manager. These meters are now utilized in measuring the current for nearly one million 16 c. p. incandescent lamps. Close upon the introduction of this meter followed the Westinghouse alternating current arc light system, in which a number of advantageous features had been developed, both in the current generator and in the lamp. The Tesla rotary phase motor was also taken up, and with it came in rapid succession the Westinghouse electric street railway system and the system for the long-distance transmission of power. In both these fields opportunities existed, which offered the greatest possibilities for a manufacturing company equipped with a producing capacity like that of the Westinghouse Company.

To give an approximate idea of the different apparatus the Westinghouse Electric and Manufacturing Company manufactures today, the following facts may prove helpful: The company manufactures alternating current apparatus for central station electric lighting plants from 500 to 10,000 16 c. p. light capacity; alternating current motors developing from $\frac{1}{8}$ h. p. to operate a fan, up to 500 h. p. for the operation of mining and mill machinery; direct current motors for the operation of electric street railways from 15 h. p. up to any capacity desired, and direct current power generators from 80 up to 1,000 h. p.

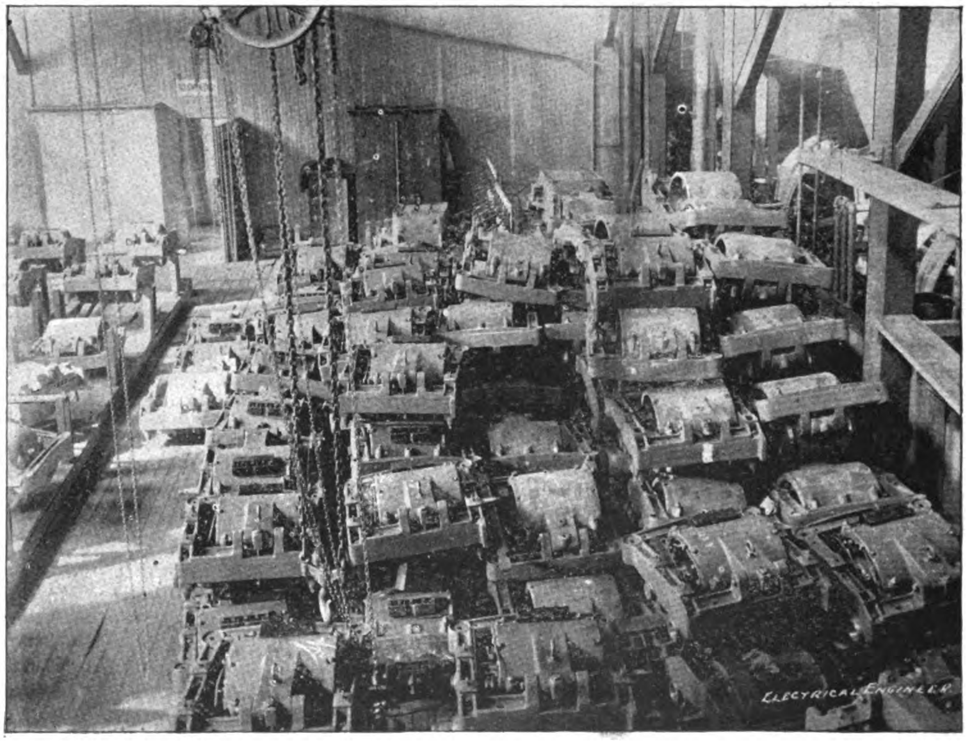
In addition to these machines, the company also makes all the apparatus used in the complete equipment of central station plants, the complete equipment for the installation of an electric street railway power plant and the complete equipment for the installation of an electric power plant for the operation of manufacturing establishments.

The Westinghouse Electric and Manufacturing Company owns a factory in New York City, and one in Newark, N. J. In the latter city the company manufactures direct current motors of all sizes and power; also direct current generators used for the operation of isolated plants, such as are installed in hotels, office buildings, apartment houses, theatres and small manufacturing establishments.

In addition to these exceptional manufacturing facilities, it owns and controls nearly one thousand important patents relating to all branches of the electrical industry.

II.

After this necessarily brief outline of the history of a company whose work is standard in both electrical and mechanical design, we propose to take the reader through the works in which is manufactured the apparatus which has found its way to nearly every town and village in the country. Following the necessary order in which material for such establishments takes its course, we find on the ground floor the office of the purchasing agent through whose hands all orders for the purchase of material and supplies of whatever nature must pass. Besides the chief a number of assistants are required to properly attend to this work, which, in a factory of this nature, daily requires many tons of material of every conceivable nature. From the office of the purchasing agent a few steps lead us to the domain of the storekeeper where all the supplies entering the building are registered and where all orders and requisitions from the



One Corner of the Railway Motor Assembling Department.

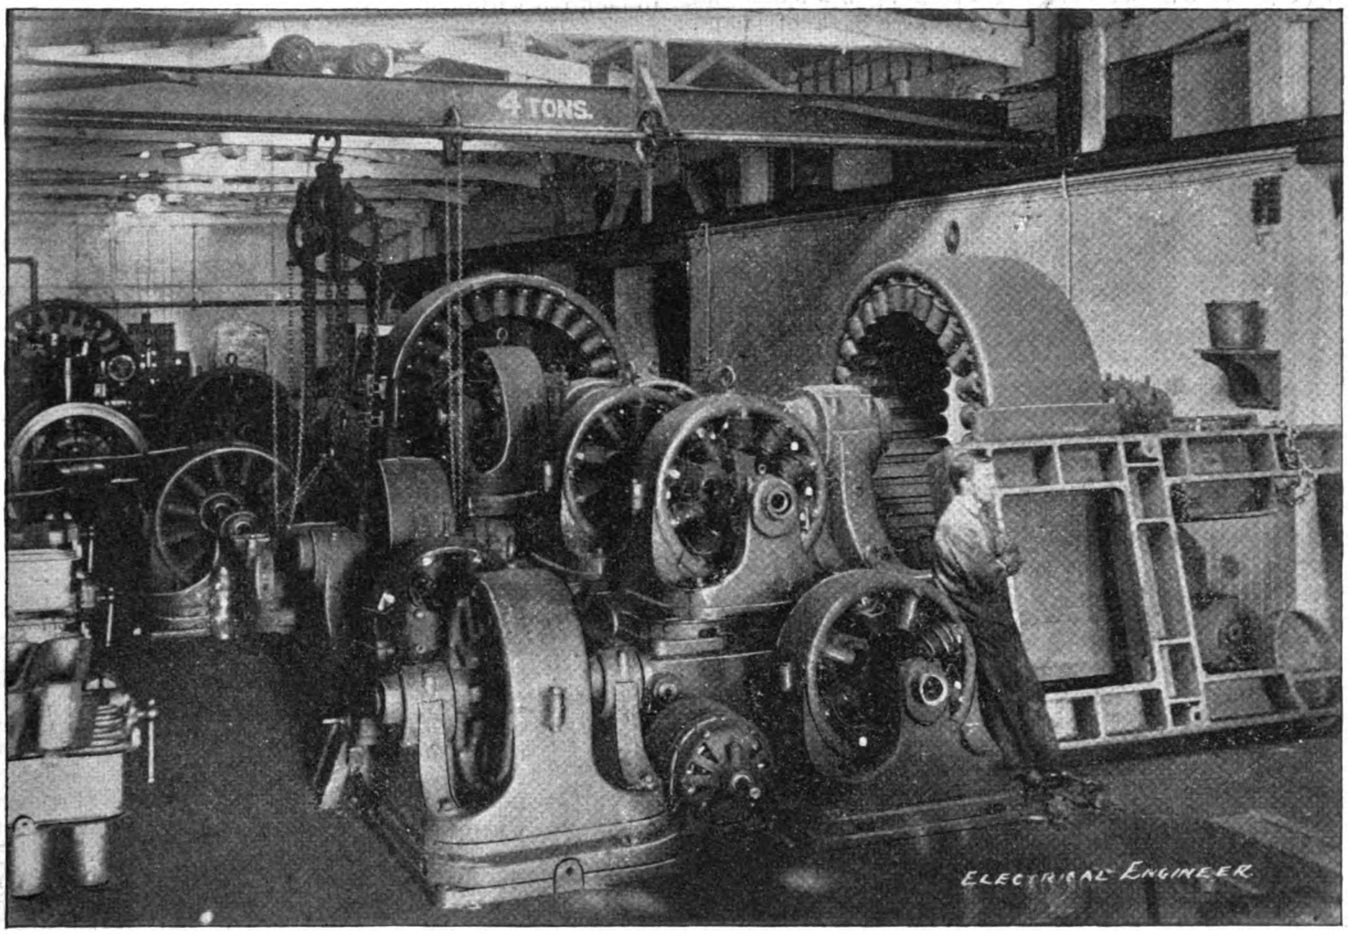
various factory departments are filled. In this storeroom we find rows upon rows of shelves and bins containing iron and brass screws, bolts, slate, marble and many tons of wire of all sizes stacked in great heaps; in addition the storeroom contains many of the finished parts which are kept in stock, such as brush-holders, armature ends, etc. Directly off from the storeroom is one of the numerous power and lighting plants which supply the various departments of the factory, this particular one being intended for the operation of the laboratory immediately overhead. This plant consists of two Westinghouse engines, one driving a continuous current machine and the other an alternator.

Passing beyond and ascending a few steps we reach the annealing department in which the sheet iron and steel employed in the construction of armature cores, converters, and the field magnet of the recently designed low frequency alternators are brought to the proper degree of softness. As much of the action of the machines depends upon the magnetic properties of the iron and steel employed, it is eminently necessary to bestow the greatest care on this part of the work, and for this purpose the sheets are packed into an annealing furnace and baked for from eight to ten hours at a uniform heat and then allowed to cool for six hours before removal from the ovens. Close besides these large annealing furnaces are others intended for the carbonizing of the lamp filaments. The filaments are packed into crucibles and baked in these furnaces heated by natural gas, and kept at an even temperature for many hours. They are then withdrawn to be further treated in the lamp department on an upper floor.

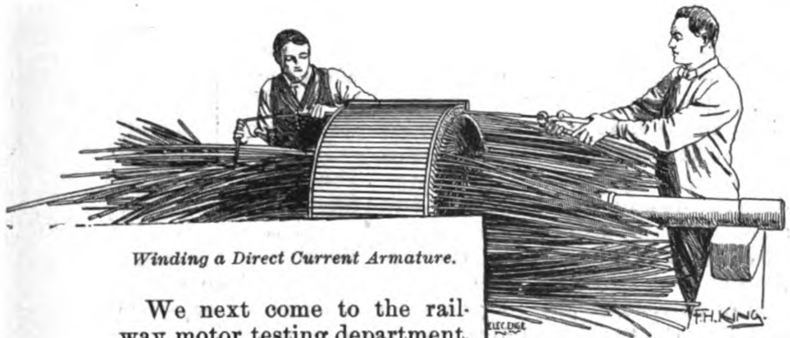
III.

A few steps further lead us to a most interesting display called the exhibition-room, in which a specimen of every apparatus and device manufactured by the Westinghouse Company is shown in practical operation. Here an attendant, by the turning of a switch, shows the manner in which the numerous mechanisms operate. The visitor learns by direct inspection the operation of the Shallenberger meter, and notes how its speed increases regularly with the addition of every lamp added to the circuit; at the same time the indicator and meter show the increased consumption of current, thus giving an optical demonstration of the fact that the true consumption is being recorded.

Another interesting part of the exhibition-room is the railway exhibit. In order to demonstrate, for example, the power and starting torque of the railway motor, the latter is connected with a dynamometer brake and scale, and by simply screwing up the brake the motor may be loaded to any desired capacity, while the visitor may compare the recording of the scale in pounds, and of the ammeter indicating the current. Added to this are several fully equipped trucks, double-reduction, single-reduction and gearless motors, together with platform switches. One of these trucks is also provided with an air brake operated by means of compressed air, supplied by a rotary air pump attached to the axle. A complete railway switchboard with automatic circuit-breakers completes this part of the exhibit. We might dwell at considerable length on the numerous devices which are shown in this interesting room, including the Tesla alternating motors, but must pass on to other departments of not less interest.



A View in the Erecting Shop—Westinghouse Electric Works, Pittsburgh.

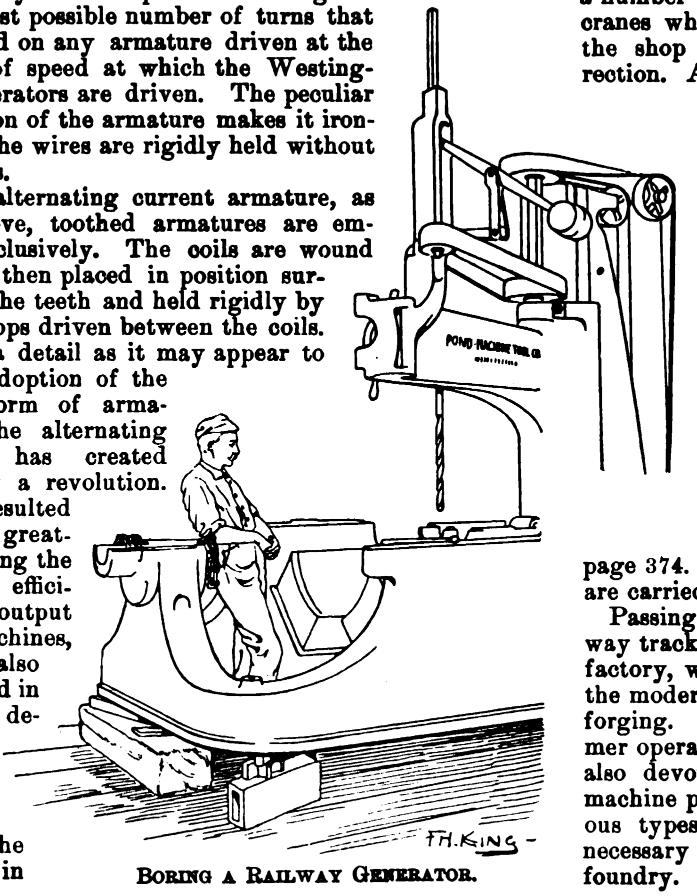


Winding a Direct Current Armature.

We next come to the railway motor testing department. Here all the machines before being shipped are given their final test, which determines not only their electrical but also their mechanical efficiency. For this purpose two machines are belted together; one operating as a motor and driving the other as a generator feeding a bank of lamps. Tests are now made at all speeds and loads; the conditions are then reversed, and the machine previously acting as a motor is driven as a dynamo by the other. Besides these mechanical tests, continuous tests for ground and other faults are carried out at a potential of 1,000 volts, that is, at twice the voltage normally supplied to the motors.

IV.

Just beyond the testing-room is the assembling department, where the fields and armatures are built up and fitted in their proper place. Our views on page 369 show a number of armatures in various stages of completion; and it will be noted that the toothed form of armature is now employed exclusively for alternating work; while for direct current the wires are placed below the external surface of the armature. A view on this page shows the operation of winding such a direct current armature. These armatures are wound with only two circuits, and all wires lying adjacent to each other are connected with adjacent bars of the commutator so that no high-tension wires touch each other at any place. There is only one turn per coil which gives the smallest possible number of turns that can be used on any armature driven at the low rate of speed at which the Westinghouse generators are driven. The peculiar construction of the armature makes it iron-clad, and the wires are rigidly held without band wires.



BORING A RAILWAY GENERATOR.

In the alternating current armature, as stated above, toothed armatures are employed exclusively. The coils are wound in a lathe, then placed in position surrounding the teeth and held rigidly by wooden stops driven between the coils. As small a detail as it may appear to be, the adoption of the toothed form of armature in the alternating machines has created practically a revolution. It has resulted not only in greatly increasing the electrical efficiency and output of the machines, but has also contributed in no small degree to their mechanical improvement. The wires held in position by the teeth are absolutely immovable, and a sudden overload does not, as formerly, lead to a straining of the wires. Besides, the ease of repairs made possible by the insertion of a new coil for a damaged one gives an additional value to this method of construction.

We have just remarked on the new departure seen in but a single detail of the machine, the armature, but we may observe the most interesting fact—and one demonstrating the thorough study to which the machines of the Westinghouse Company are constantly subjected—that hardly a single piece of apparatus now being built at these works is of exactly the same pattern as that built barely a year ago.

The railway motor assembling-room presents a busy scene, and an indication of the pressure of work in this department can be but vaguely conveyed by our illustration on page 370, which shows a pile of railway motor fields ready to be fitted with axle bearings.

V.

Finishing Slot in a Brush Holder.

The heavy machine tool shop, illustrated on page 374, occupies more than half the space of the square covered by the works. Our view on page 374 can give but an inadequate idea of the number and size of the machines here at work. Immense lathes, planers and boring mills finish the castings as they come from the foundry. And the handling of these heavy masses is very easily accomplished by a number of overhead cranes which traverse the shop in every direction. A large number of special tools are also at work, designed for the purpose of rapidly reducing the rough material to its finished shape, and thus effecting economy in time and cost of manufacture. Indeed, a notable feature of the equipment of the Westinghouse Works is the employment, wherever possible, of machines and devices for economizing time in manufacture, and also for the purpose of securing uniformity and interchangeability of parts. For this purpose, standard gauges are employed throughout the Works, so that when the parts are ready to assemble a touch of the file is scarcely required to fit them in their proper positions.

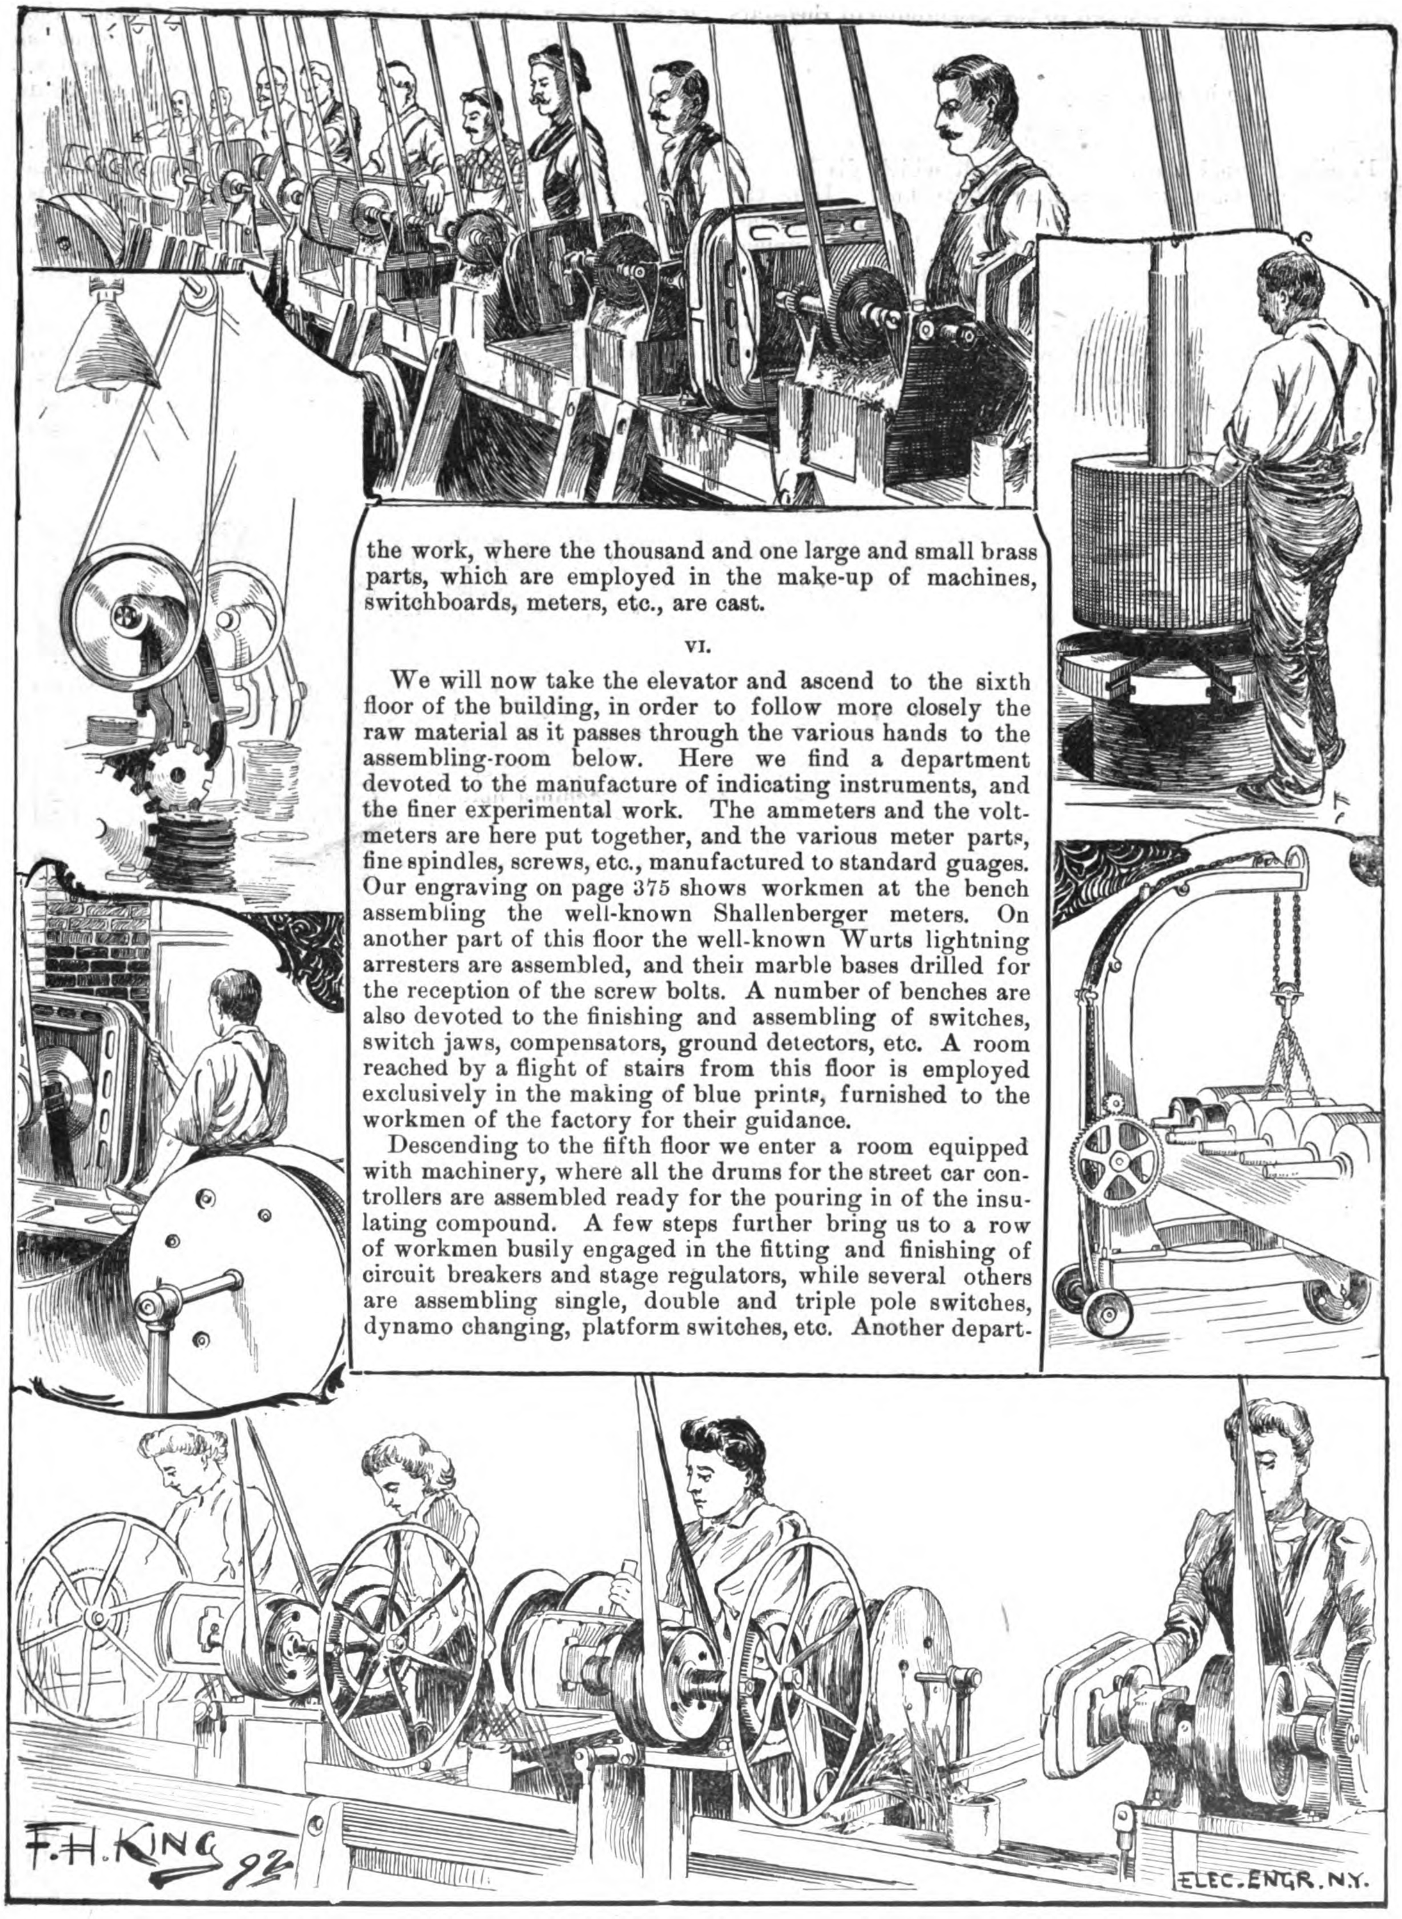
At the north end of this machine shop a line of heavy shafting drives the large alternating and continuous current generators undergoing test, a partial view of which is also shown on page 374. These tests, like those of the railway motors, are carried out with great care.

Passing out from the heavy machine shop across the railway tracks, by which the material is shipped from the factory, we find the blacksmith shop, equipped with all the modern tools, such as steam and drop hammers for rapid forging. Among the tools here employed is a drop hammer operated by an electric motor. Separate buildings are also devoted to the carpenter shop, where the various machine patterns and the woodwork required in the various types of apparatus manufactured, are finished. A necessary adjunct of every electrical shop is a brass foundry. A separate building is devoted to this part of the work, where the thousand and one large and small brass parts, which are employed in the make-up of machines, switchboards, meters, etc., are cast.

VI.

We will now take the elevator and ascend to the sixth floor of the building, in order to follow more closely the raw material as it passes through the various hands to the assembling-room below. Here we find a department devoted to the manufacture of indicating instruments, and the finer experimental work. The ammeters and the voltmeters are here put together, and the various meter parts, fine spindles, screws, etc., manufactured to standard guages. Our engraving on page 375 shows workmen at the bench assembling the well-known Shallenberger meters. On another part of this floor the well-known Wurts lightning arresters are assembled, and their marble bases drilled for the reception of the screw bolts. A number of benches are also devoted to the finishing and assembling of switches, switch jaws, compensators, ground detectors, etc. A room reached by a flight of stairs from this floor is employed exclusively in the making of blue prints, furnished to the workmen of the factory for their guidance.

Descending to the fifth floor we enter a room equipped with machinery, where all the drums for the street car controllers are assembled ready for the pouring in of the insulating compound. A few steps further bring us to a row of workmen busily engaged in the fitting and finishing of circuit breakers and stage regulators, while several others are assembling single, double and triple pole switches, dynamo changing, platform switches, etc. Another depart-



VIEWS IN THE WINDING, STAMPING AND ARMATURE CORE DEPARTMENTS.

ment on this floor is devoted to the assembling of rheostats of all sizes and forms. The German silver or heavy iron wire is supported on porcelain insulators fixed in iron frames, so as to be thoroughly fireproof.

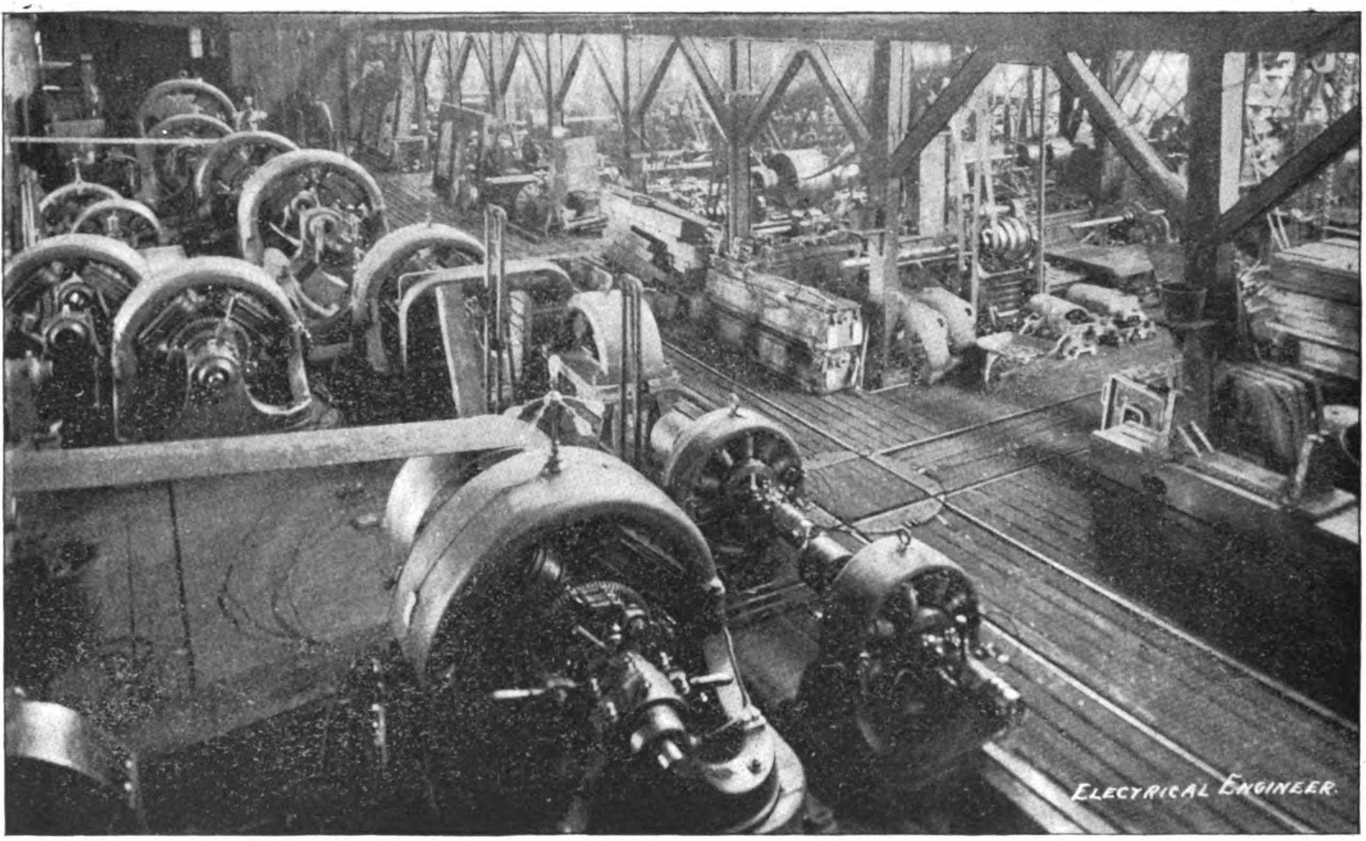
VII.

Passing beyond the heavy fire wall which divides the building, we enter the converter department. Here the stamped sheets of soft steel are built up around the converter coils and pressed into a solid mass. The employment of soft steel in place of iron has resulted in a great increase in the output, as well as in the efficiency of these converters. The method of building up these sheets without the interposition of paper or other auxiliary insulating material might at first thought give rise to unfavorable criticism, and, not very long ago, would have been considered little short of suicidal. But it was Mr. Albert Schmid, the superintendent of the Westinghouse Works, who discovered that the sheet material could be given a coating of oxide, which would thoroughly insulate plate from plate electrically, and thus obviate the necessity of interposing sheets of paper as had heretofore been done; and this method is now carried out in all the Westinghouse laminated work, not only in converters but also in armatures and laminated pole-pieces. At one side of the room a complete testing outfit is arranged for subjecting the converters to a thorough test before allowing them to go out. For this purpose each transformer is run for four hours at 20 per cent. beyond its rated capacity. On this floor also, the laminated pole-pieces intended for the new low-frequency Westinghouse alternator are built up, to be afterwards cast into a ring frame, forming a continuous magnetic yoke.

VIII.

We now enter the tool room, that important part of every large manufacturing establishment, where all cutters, punches, dies, jigs, etc., are finished to be delivered to the machinists in charge of the machine tools. Among the numerous excellent tools with which this department is equipped, may be noticed two oscillating emery planers. These machines, which are constantly at work, are built to handle large surfaces, such as are presented by the dies intended for punching out large armature plates. The object to be surfaced is fixed to a planer bed, and the emery wheel, besides its ordinary motion of revolution, is given a transverse motion at right angles to the bed of the planer; thus each part of the wheel is brought into action. This keeps it true automatically, and thus insures a thoroughly plane surface.

Retracing our steps and passing to the fourth floor below, we enter the department devoted to the assembling of armature cores. These are put together much in the same way as the converter cores, being placed one above the other in the shaft, and pressed into a solid mass. Then the ends are screwed on them and they are passed to workmen who file them down thoroughly and finish them ready for the reception of the winding.

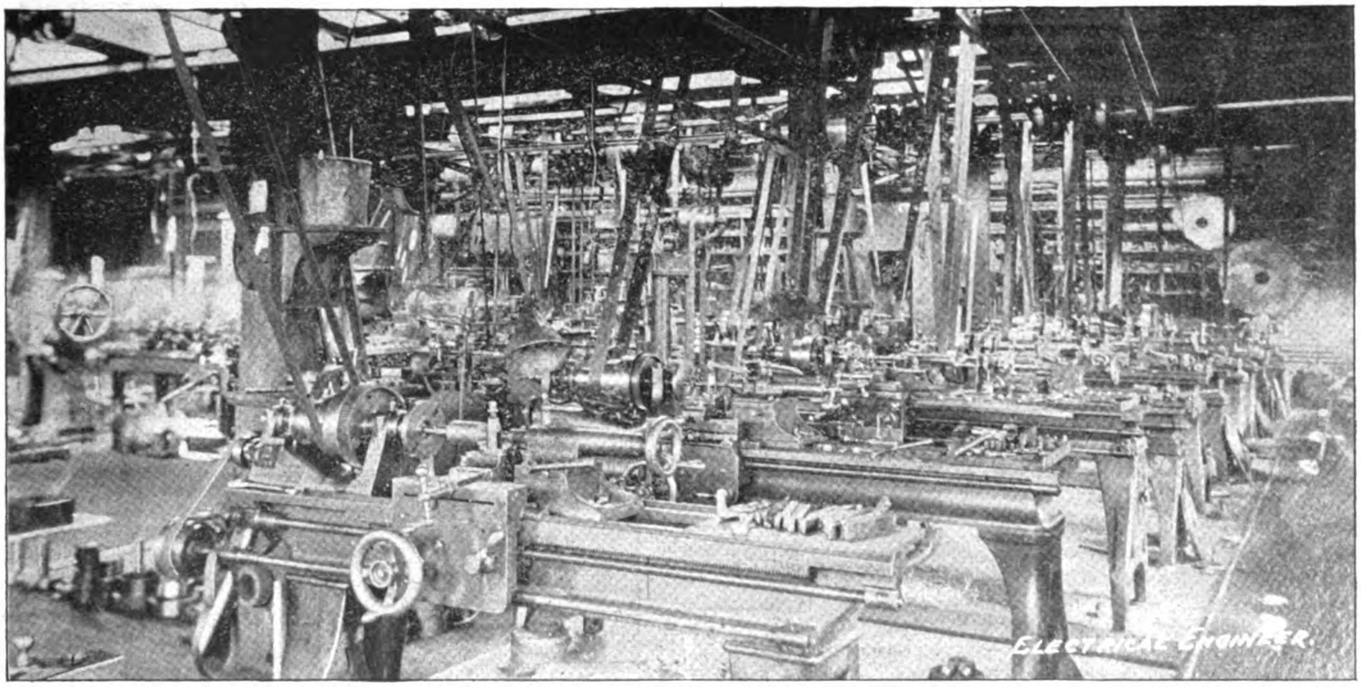


A CORNER OF THE HEAVY MACHINE SHOP AND DYNAMO TESTING DEPARTMENT.

The work in this department, as well as in others throughout the factory, is greatly facilitated by the employment of portable cranes. By means of these an armature core weighing several hundred pounds is lifted directly into a lathe and requires only a boy for its manipulation. One of these cranes is shown on page 373. An interesting process, and one illustrating the care which is bestowed upon the details of manufacture in the Westinghouse Works can be seen here. In finishing the slots of the brass brush holders much time would be required in filing, as machine work is practically impossible in this case. To save the time which would be thus occupied, steel cutting plugs are employed, which the workman drives through the slots by blows of a hammer. The operation is shown in our engraving, page 372, and the result is a perfectly smooth slot, exactly to gauge, and which requires not a touch of the file.

ELECTRICAL ENGINEER.

Assembling Shallenberger Meters.

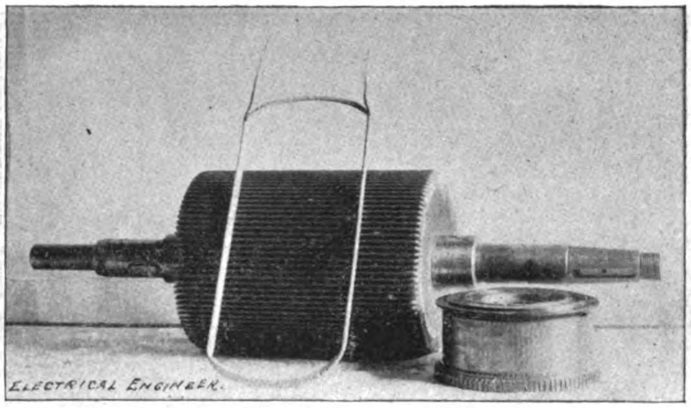


A Section of the Tool Room.

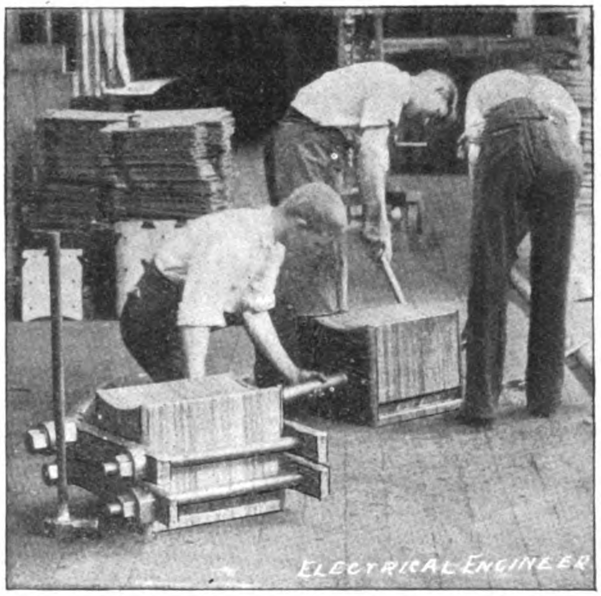
Passing through a partition, which keeps out all dust, we enter the rooms devoted to the testing of voltmeters, ammeters, station indicators, circuit breakers, as well as house meters. All these instruments are subjected to a thorough test and compared with standard instruments. Thus, the house meters are given a prolonged run, and their indications are continually checked by the reading of an electro-dynamometer. The durability and the careful construction of all the Westinghouse apparatus is strikingly illustrated in this meter. As has been already stated, there are now meters in operation measuring the current of nearly 1,000,000 16 c. p. incandescent lamps, and less than one per cent. of this total amount sold has ever been returned to the shop for any defect whatsoever.

IX.

Passing through the portals protected by heavy fire doors, we enter the armature winding department. Here the cores are first thoroughly covered with Fuller board and canvas soaked in insulating material and the coils then applied. One of our engravings shows a railway armature in three stages of progress of winding. The employment of specially wound coils for the railway armatures makes their winding very simple, and permits of easy replacement in case of damage, a process which involves some difficulties in the ordinary Siemens wound drum. Close beside are a number of benches devoted to the winding of the small solenoid coils of the Westinghouse arc lamps. When finished they are brought to the front of the building, which constitutes the assembling and test room for arc lamps, a view of which is given on page 377.



Railway Armature Core, Coil and Commutator.



Building up Laminated Pole-Pieces for Railway Generators.

On another part of this floor the car controllers are assembled. The interstices between the contacts are filled with insulating compound, giving the whole a perfectly cylindrical surface. Partitioned off from the rest of the work on this floor is the buffing shop where the many small parts are polished, ready to be lacquered.

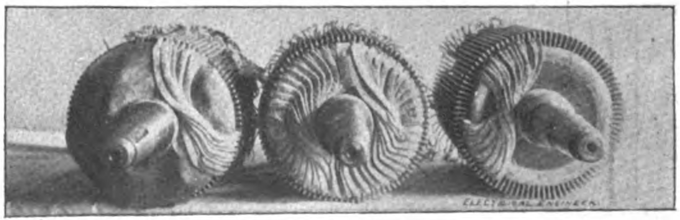
X.

The winding of the field magnet coils for the various types of generators and motors, as well as those intended for converters is done on the third floor. Our engraving, on page 373 hows clearly this operation which requires a considerable amount of skill and care. Each layer of wire is thoroughly insulated from its neighbor. The spools placed between lathe centres are driven by a belt from overhead, workmen guiding the wire into the proper channel as the spool revolves. During our visit this department was driven to its utmost capacity owing to the heavy demand for prompt delivery, especially of the electric railway apparatus, for which there is simply an enormous demand.

XI.

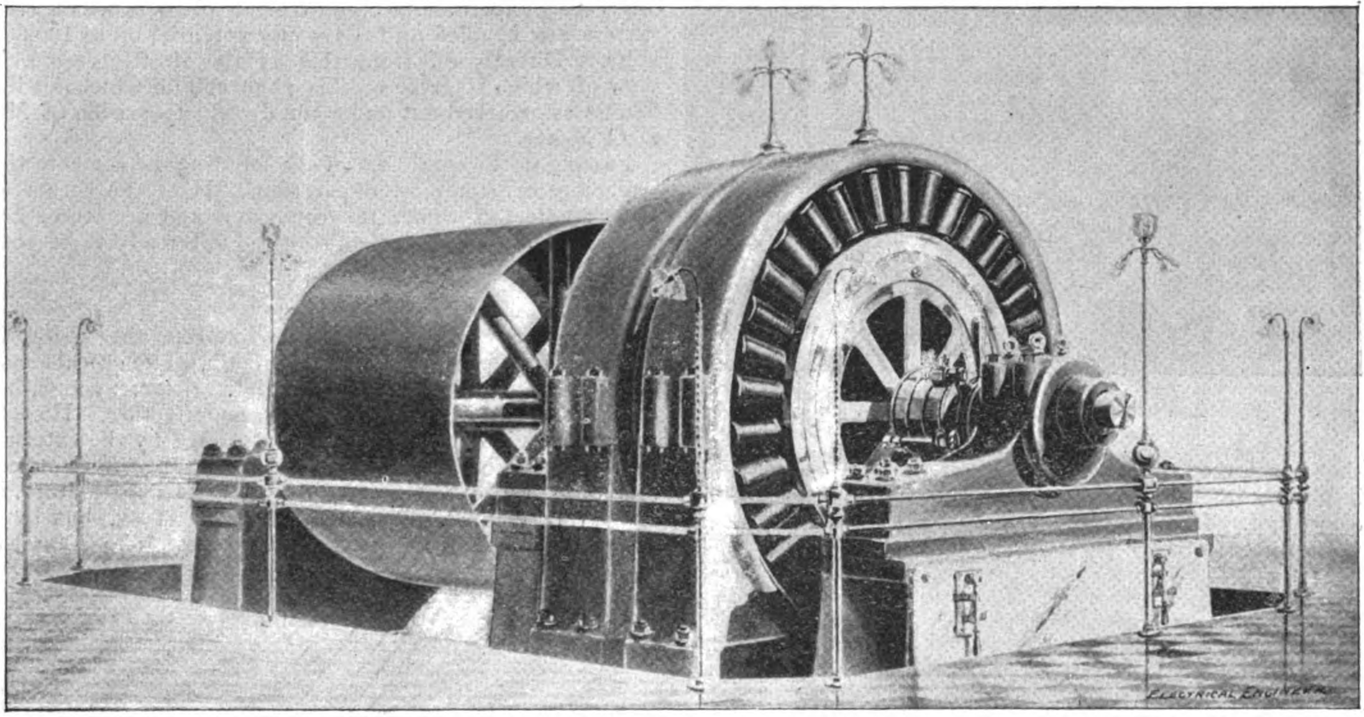
The filaments employed in the lamp manufacture are made in the Pittsburgh factory. As they come from the carbonizing furnaces, they are delivered to girls who place each filament in clips which are then covered by a glass globe from which the air is first exhausted by means of vacuum pumps. After the air is exhausted, hydrocarbon gas is admitted; the current being then turned on, the filament is brought to incandescence and the deposit of carbon from the hydrocarbon gas ensues. The flashing process gives the filament a uniform texture through its entire length, and when the proper resistance has been reached, the current is automatically cut off. Each girl operates two stands, one of these exhausting and the other flashing. In addition to the automatic arrangement for obtaining the correct resistance, each filament is additionally measured by means of a Wheatstone bridge.

Finishing an Alternating Current Collector.



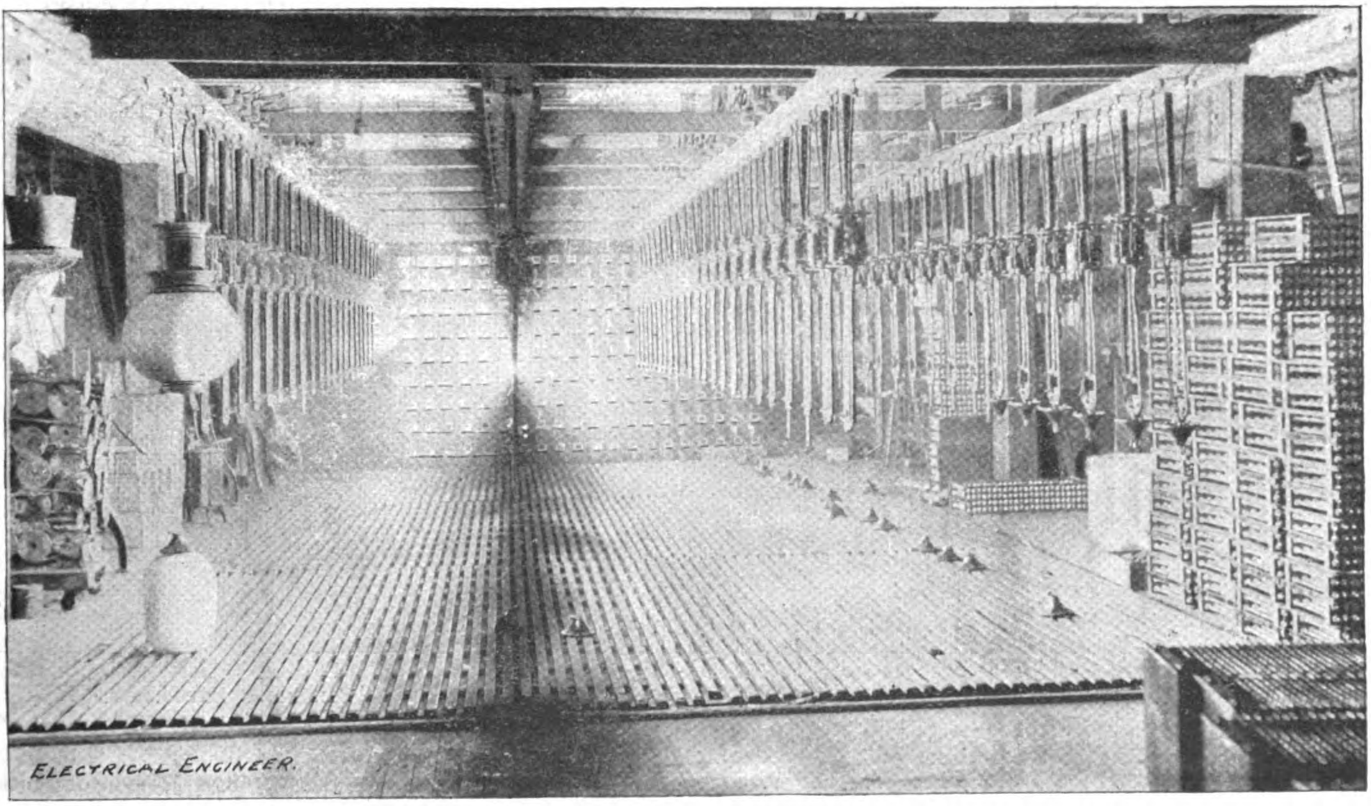
Railway Motor Armatures.

Adjoining the flashing department is the experimental shop where work is constantly going on to devise improvements in lamp manufacture.



10,000-Light Belt Driven Alternator for the World's Columbian Exposition.

The other side of the building on this floor is occupied by a series of gear cutters which operate automatically; the gear blanks, once inserted, require no attention until the gear teeth are finished. Here also, the gear cases which protect the gears from dust under the cars, and serve to deaden the noise of the gears, are fitted. The commutator and collector departments are also situated on this floor and offer a striking object lesson on the comparative simplicity and cheapness of construction of the latter as compared with the former.



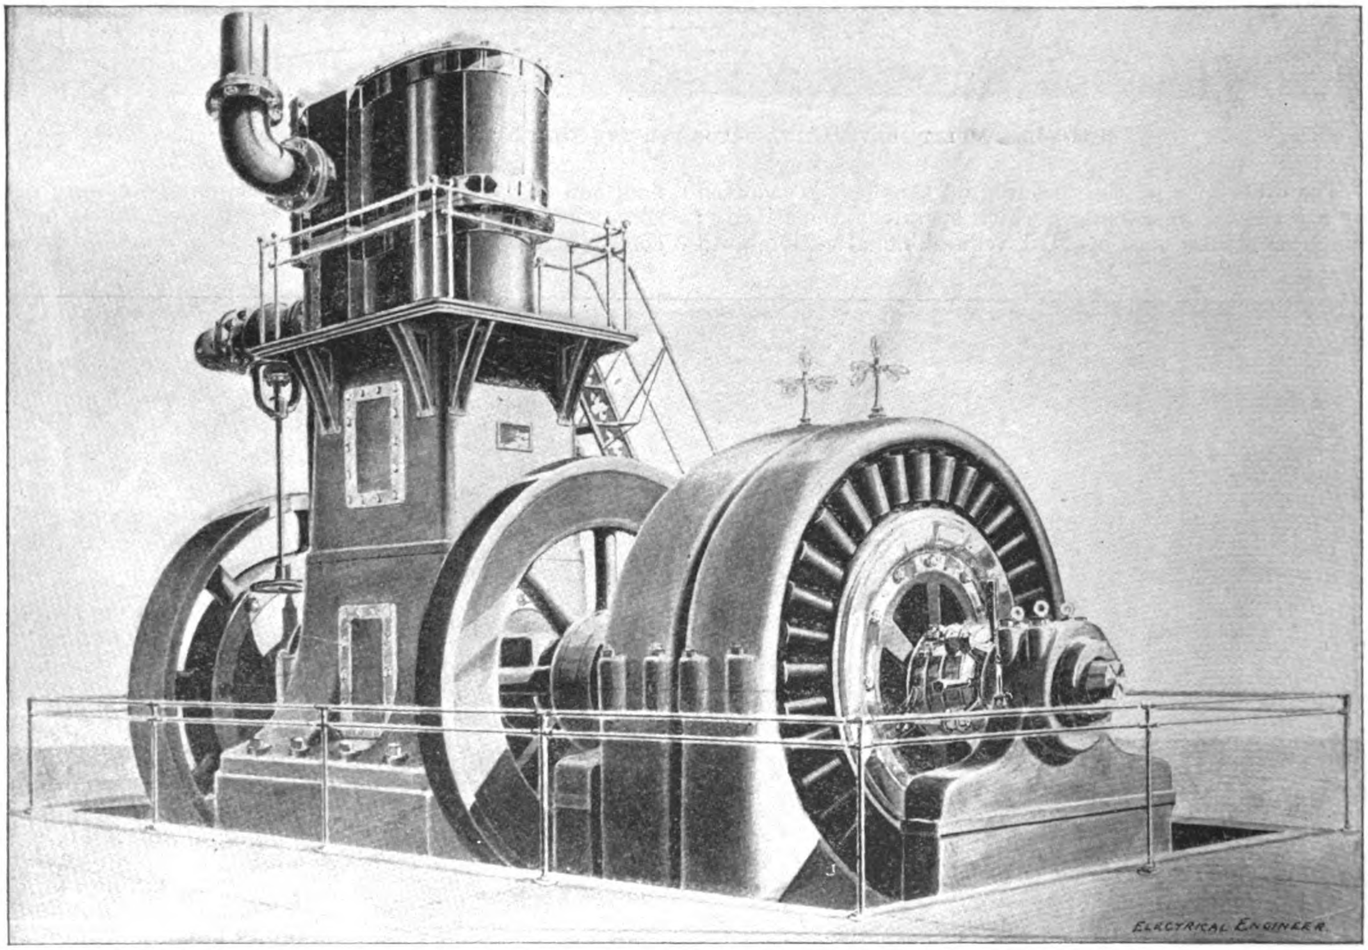
Testing Room for Alternating Arc Lamps.

XII.

Passing to the floor below, an army of girls may be seen

A VIEW IN THE DRAFTING ROOM.

taping and insulating the converter, field magnet and armature coils. The field magnet coils are first thoroughly shellacked, then covered with Fuller board, and wound with insulating tape and finally dipped in a special insulating compound. The primary and secondary coils of the converters are wound separately and then slipped over each other before insertion in the iron cores. This feature of separately winding the primary and secondary coils of the converters is controlled by patents of the company and by this means the greater durability and higher efficiency of the Westinghouse converters is largely assured. As we pass through the room we notice a long bench at which girls are sorting and cutting mica sheets which enter into the insulation of the commutator segments and a variety of other apparatus.



1,000 H. P. WESTINGHOUSE 2,000-VOLT QUARTER PHASE GENERATOR, FOR WORLD'S COLUMBIAN EXPOSITION.

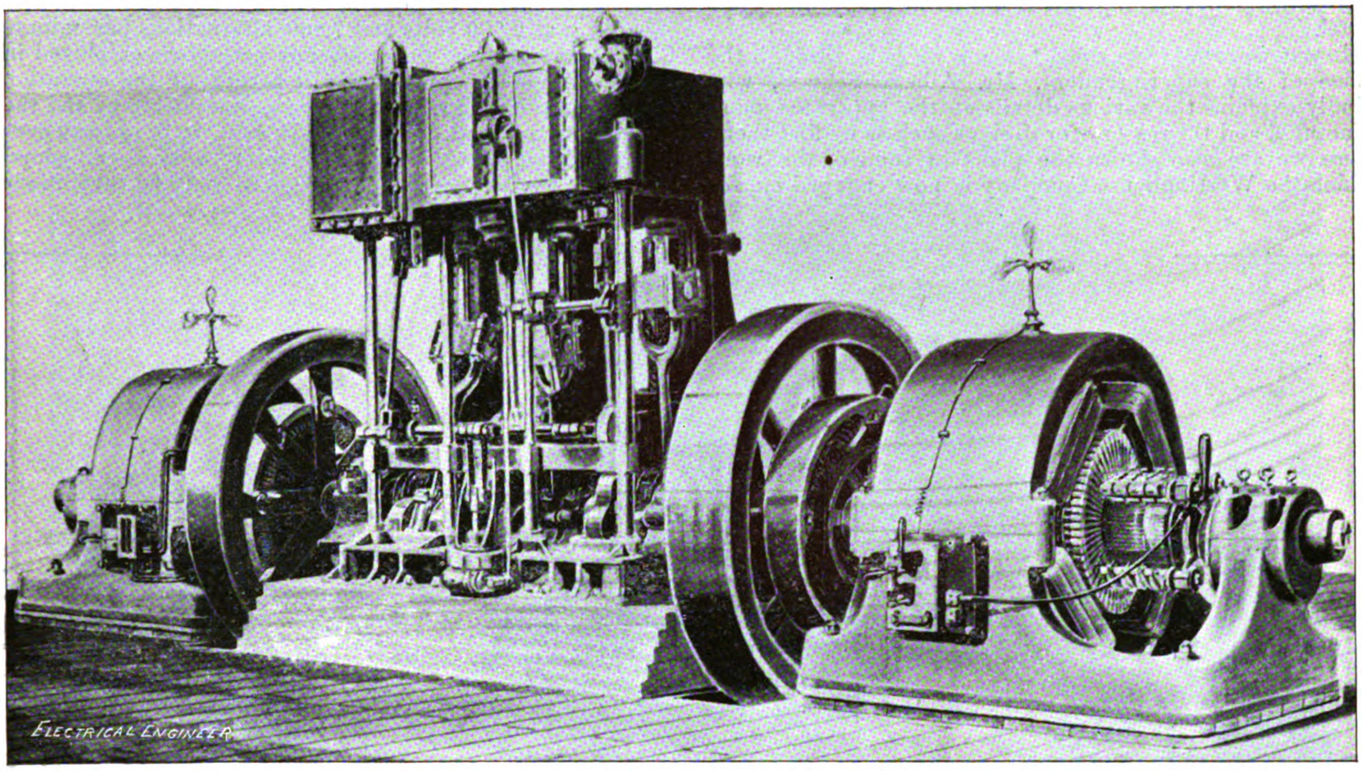
In the room adjoining this department we find a very interesting experimental high tension plant in which converters are coupled up to give any potential up to 100,000 volts. Directly off from this is the drafting-room, a view of which is given on this page and in which all the details are worked out under the direct supervision of Mr. E. C. Means.

Passing to the south end of the building we come to the punching or stamping department. Here the sheets of iron and steel of which the converters and armatures are made are first sheared, then stamped out ready to be sent to the assembling departments.

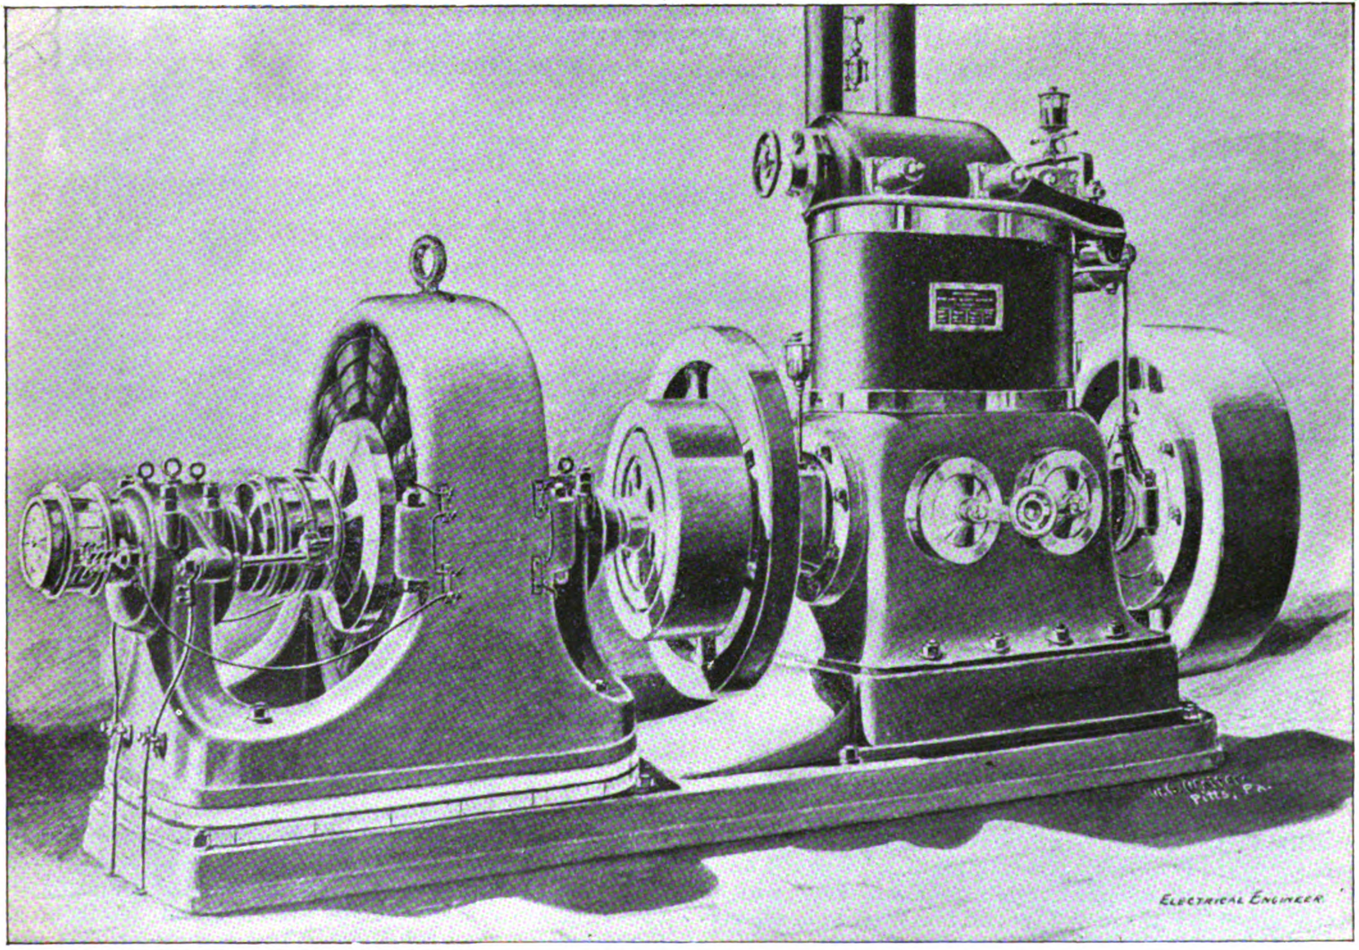
XIII.

In this hasty walk through the building the visitor is everywhere impressed with the thorough, systematical handling of all apparatus and material, without which, of course, there can be no economy in manufacture. His attention in this connection is also attracted by the extreme cleanliness observed. Dust, the great enemy of electrical apparatus, especially in the course of its manufacture, is effectively combatted, not by the usual brush, but by a complete system of compressed air piping. This is tapped at innumerable points and by flexible tubing, is brought by the workman to the necessary points. The strong blast blows all dust out of holes and cavities which to a brush would be inaccessible.

The welfare of the workmen is also thoroughly considered and the neat porcelain enameled wash-basins and polished faucets in every department will stand compari-



Two 250 H. P. Westinghouse Multipolar Railway Generators Direct Connected to Globe Iron Works Triple Expansion Engine.



Westinghouse Alternator Direct Connected to Westinghouse Engine.

son with similar arrangements in almost any first-class hotel.

In our passage from shop to shop we pass through the office of the superintendent, Mr. Albert Schmid, who kindly explains the various details of the apparatus manufactured and the reasons for designs such as we find them. Here we are also shown the plans of some of the work which the Westinghouse Company is now engaged on, for supplying the World's Columbian Exposition, at Chicago, with light and power. The power plant which will be there shown will be a striking example of large power units in various types of generators; four of these will be driven direct by the new type of the Westinghouse vertical compound engine. The armatures of these machines will be of the toothed type, with removable coils and composite wound for constant potential. Besides this there will be six machines, belt driven, one of which will be a thousand horse power, quarter phase, alternating generator operating at 2,000 volts and 7,200 alternations per minute This departure from the frequency heretofore employed in the Westinghouse apparatus will permit of the operation on the same circuit of arc and incandescent lamps and the Tesla motors as well. Besides this, a 500 h. p. railway generator will be shown coupled direct to a cross-compound Reynolds-Corliss engine operating at only 90 revolutions per minute. Our engravings on pages 377, 378, 379 and 382, will give a good idea of the magnitude of this work.

Philip Lange.

Albert Schmid.

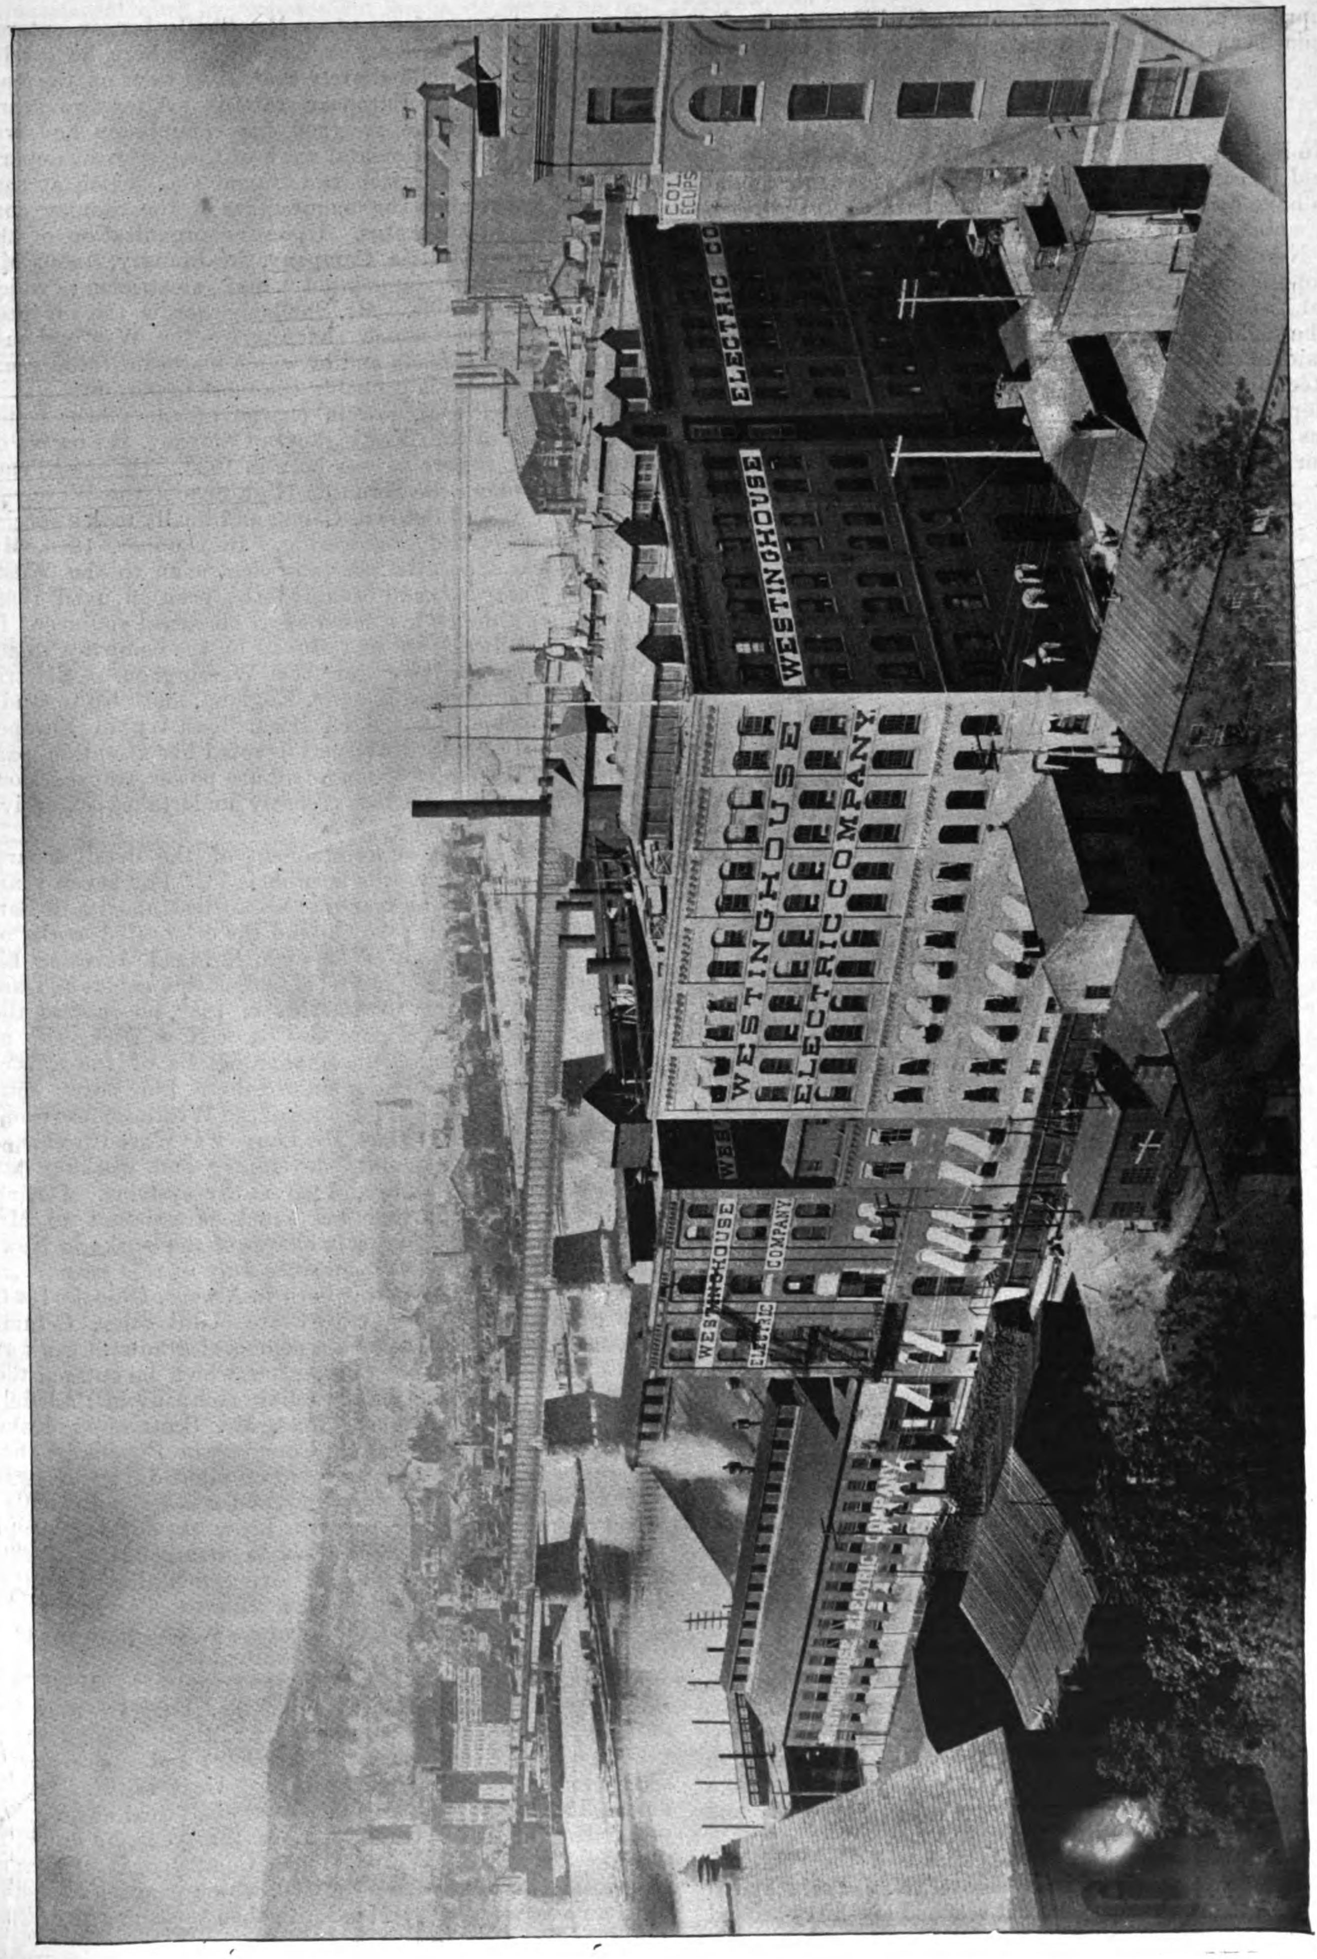
TECHNICAL STAFF;
WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY,
PITTSBURGH, PA.

C. F. Scott.

L. B. Stillwell.

F. S. Smith.

The laboratory of the works, now under the direct charge of Mr. Charles F. Scott, is situated immediately above the main offices. Here the electrical details of all the apparatus are worked out. The laboratory also constitutes the standardizing bureau for all electrical shop instruments of every description and various investigations are constantly going on. The equipment of the laboratory



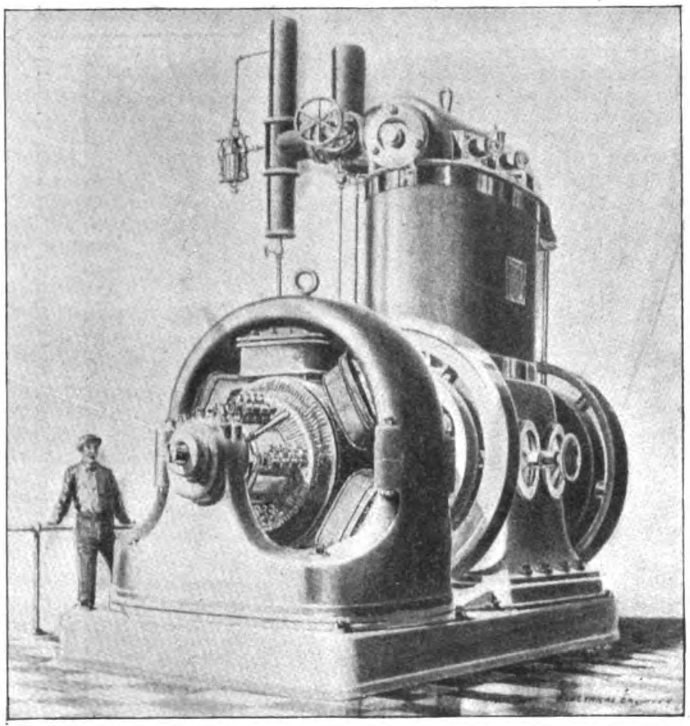
General View of the Westinghouse Electric Company's Works; Pittsburgh, Pa.

comprises a complete equipment of the most modern standard apparatus of both continuous and alternating type.

XIV.

No account of the work of the Westinghouse Company would be complete without a few words regarding the men who have contributed to bring the apparatus to the perfection which it now exhibits. We have already alluded to Mr. Nikola Tesla, whose recent enthusiastic reception in Europe is one of the most striking episodes in modern electrical history.

The technical staff of the Westinghouse Company may be said to offer a striking example of the value and demand for technical training, for without exception the heads of all departments are men who are graduates of colleges. This forms a striking contrast to conditions presented in manufacturing establishments of many older industries in which they who are frequently misnamed "practical men," or those who have graduated from the machine shops, rule the destinies of manufacturing works.



500 H. P. Railway Geneator Direct Connected to Westinghouse Engine.

The mechanical superintendent of the works, Mr. Albert Schmid, was born at Zurich, Switzerland, in 1858, and graduated from the celebrated Polytechnic in that city. In his early career he obtained considerable experience in the manufacture of steam engines, locomotives, turbines and electrical apparatus, widening his experience by sojourns in England, France, Belgium, Switzerland and Germany. In 1882, Mr. Westinghouse induced Mr. Schmid to come to Pittsburgh, where he entered the employ of the celebrated Westinghouse Air Brake Co. Upon the organization, shortly after, of the Westinghouse Electric Co., Mr. Schmid was placed in charge of the manufacturing department which position he has held ever since. In conjunction with Mr. Westinghouse, Mr. Schmid justly shares not a little of the credit for the admirable construction and design of the Westinghouse apparatus.

Mr. O. B. Shallenberger, the electrician of the Westinghouse Company, was born in Rochester, New York, and is still a young man, having now but reached his thirty-second year. At the age of seventeen Mr. Shallenberger entered the U. S. Naval Academy at Annapolis, where he graduated in 1881, and immediately thereafter went on the customary cruise to the European stations. After two years' service, however, he resigned his commission and was engaged in the experimental work of the electrical department of the Union Switch and Signal Co., which at that time had undertaken the manufacture of the Stanley continuous current apparatus. Upon the organization of the Westinghouse Electric Company, in January, 1886, Mr. Shallenberger was appointed chief electrician; which position he still holds. Mr. Shallenberger is the inventor of many features which characterize the Westinghouse apparatus as now made and of which his beautiful alternating current meter is probably the most important.

Mr. L. B. Stillwell, now in charge of the power transmission work of the Westinghouse Company, is a native of Scranton, Pa., where he was born in 1863. He passed successively through the Scranton High School, the Wesleyan University at Middletown, Conn., and finally took a special course in electrical engineering. In October, 1886, Mr. Stillwell was appointed assistant electrician to the Westinghouse Company, and occupied the position until 1889, since which time he has acted as its electrical engineer. In 1890, Mr. Stillwell was sent abroad by the company to act as consulting engineer for the Westinghouse Electric Company, Limited, in London, England, and also to study the development of the electrical industry in Europe. More recently Mr. Stillwell has devoted his attention particularly to the study of long-distance power transmission, for which purpose he has recently undertaken extensive trips South and West.

Mr. Philip Lange, superintendent of the detail department of the company, was born in 1856. For seven years he was engaged in the manufacture of instruments in Berlin, Germany, and in 1880 entered the celebrated works of Siemens Bros. & Co., of Woolwich, England, devoting his attention to the manufacture of submarine cables and arc lamp work. Coming to America in 1882, he entered the service of Messrs. Bergmann & Co., of New York, who at that time manufactured the smaller details of the Edison system of lighting. He remained there four years, until 1886, when he entered the service of the Westinghouse Company at Pittsburgh. Here Mr. Lange was placed in charge of the "detail department," developing and working out the details of alternating and street car systems. During the last year Mr. Lange has acted as assistant to Mr. Schmid, and as such is now in charge of the works in Newark, N. J., where he has been since July of this year.

Mr. Charles F. Scott was born in Athens, Ohio, in 1864, and graduated at the Ohio State University, Columbus, in 1885. He then took a course of graduate work at the Johns Hopkins University, after which he entered the electrical field with a constructing company in Philadelphia in 1887. In August, 1888, Mr. Scott entered the employ of the Westinghouse Company in Pittsburgh, beginning work in the dynamo room on night duty. He was soon transferred to the laboratory, and was assistant to Mr. Tesla during the latter part of his work on alternating motors at Pittsburgh. After the departure of Mr. Tesla, Mr. Scott was placed in charge of experimental work on the Tesla motor. Mr. Scott has been assistant electrician for the last year in charge of the laboratory, and part of the time during the absence of Mr. Shallenberger.

The superintendent of the lamp department, Mr. F. S. Smith, was born in 1863, at Kingston, Pa. In 1882 he entered the Wesleyan University at Middletown, Conn., taking a two years' course of chemistry and the natural sciences; he then proceeded to Lehigh University at Bethlehem, Pa., where he took a course in analytical chemistry, graduating in 1887. On June 1, of that year, he entered the service of the Westinghouse Company as assistant superintendent of the lamp factory, which position he held for a number of years. Mr. Smith then took charge of the experimental work in incandescent lamps, to which he devoted a year, and since then he has been superintendent of the lamp department, in addition to that of the experimental work.

Mention must also be made here of Messrs. B. G. Lamme, E. C. Means and H. P. Davis, who have been connected with the Westinghouse Company for a number of years, and who have ably assisted Mr. Schmid in the designing of the Westinghouse apparatus.

XV.

In the above we have limited ourselves to the description of but one of the manufacturing establishments of the Westinghouse Co. But some detailed mention must also be made of the factory in Newark, N. J. These works, which are in charge of Mr. Philip Lange, cover nearly an entire block, and are five stories high. It is here that the large direct current dynamos for isolated lighting, electrolytic work, etc., are manufactured, and, also, motors of all sizes.

In the foregoing the writer has endeavored to give, as nearly as possible, an accurate description of the most important departments of the works of the Westinghouse Electric and Manufacturing Company in Pittsburgh. It is not meant to be a complete description of everything he saw there, indeed such a task, while it would be a pleasant one, would make this issue of the ENGINEER much too bulky. It is safe to say that there is no other electric company in the world, the product of which affords more of interest to the electrical industry and the public in general, than does that of the Westinghouse Company.

Rarely, indeed, is there a manufacturing company, either in the electrical or any other industry, which in the short space of time, of less than a decade, can produce a record of achievements equal to that of the Westinghouse Company. Their product has in that time been sold in every corner of the globe. Their apparatus is operating in gold mines in Colorado, in coal mines in Pennsylvania; it generates electric current for lighting one of the largest parts of the city of London, England, as well as towns in China, Japan and Australia. Its apparatus for the operation of electric railways has within two years revolutionized the entire manufacture of electric motor systems. There is, in fact, not a branch or a field in the electrical industry that is not occupied by this enterprising corporation.

LETTERS TO THE EDITOR.

TWISTING MAGNETISM AND UNIPOLAR MACHINES.

As one who is deeply interested in any line of experimental work that may lead to new results, I read with interest the article entitled "Twisting Magnetism" which appeared in your issue of Sept. 7, in which Mr. Balch describes the ingenious manner in which he has sought to "coil" the moving conductor and thus produce a machine capable of generating a higher potential than has been common to this class of dynamos in the past. Although these experiments have been without result so far, owing seemingly to his inability to "twist" magnetism, still they are productive of great good in pointing out to the investigator in this field, a new and possible way in which the desired result can be obtained, providing, of course, that the present apparently insurmountable difficulties may be overcome.

I was therefore greatly surprised to read in your issue of Sept. 21 a communication from Mr. J. C. Reusch condemning the machine of Mr. Balch by a rule set forth by Silvanus P. Thompson in his work on "Dynamo-Electric Machinery," to cover an entirely different class of machines, *i. e.*, the ordinary bipolar or multipolar dynamo in which the current is produced in the conductor by "altering the number of lines of force that flow through it." If I understand the matter correctly, this rule was never meant to apply to unipolar machines, one of which, the dynamo of Prof. Forbes is illustrated and described in the above-mentioned work. In this machine, the conductor moves between two magnetic forces of opposite polarity so that there is a continuous cutting of the lines of force by the conductor, but no alteration in the number of such lines passing through the "circuit of which the moving conductor forms a part." In this machine the field is perfectly uniform and "the conductor is moved by a motion of translation to another part of the uniform field" and does produce a current, notwithstanding Mr. Reusch's sweeping quotation to the contrary.

It seems to me that it is unfair to Prof. Thompson to quote his words in respect to one class of dynamos in condemning a modification of another distinct class, and that Mr. Reusch has not given the subject the attention it deserves when he so quotes him. Even had so eminent an authority as Prof. Thompson laid down this law to cover this class of unipolar machines, it does not appear that it should be set up as a barrier in the way of the experimenter, who, in the range of possibility may find instances in which this law should be qualified.

I have written as above because I feel that an injustice has been done Mr. Balch in thus supposing him to be unacquainted with a rule that is generally supposed to be the A B C of practical dynamo construction and not because I am able to suggest an explanation of the reason his machine does not yield a current, other than by saying that in this machine at least, magnetism *does not twist*, this being the only essential difference between it and the dynamo of Prof. Forbes in which twisting magnetism is not required. Whether magnetism can be made to twist, or not, is good subject-matter for experimental work and the individual who can first say why it does or will not twist is the one who can justly point out to Mr. Balch the error of his ways.

W. E. HYER.

NEWBURGH, N. Y., Sept. 26, 1892.

UNIPOLAR DYNAMOS—A SUGGESTION.

To endeavor to extricate a fellow-being who has fallen into one of "the many traps by which the venturesome inventor is ensnared in Dame Nature's unexplored domain," should be a more laudable desire than to simply point out to him the danger after his fall!

Mr. Reusch has courteously indicated to Mr. S. W. Balch why his dynamo-electric machine, described in an article entitled "Twisting Magnetism," was unable to furnish current;—allow me to suggest how that machine may be transformed into a current producer.

I believe I am right in stating that all magneto-electric induction currents consist of a succession of wave motions, and in graphically describing them we invariably draw a curve. The alternating current, if analyzed, no matter how rapid the alternations may be, is a succession of waves. The so-called continuous current also consists of waves, even if we carry out our system of commutation to the last degree. This is unavoidable, for, to obtain any current at all, the lines of force cut through by an inductor traveling in a magnetic field, must be more numerous in some parts than in other parts of that field. In other words the intensity of the magnetic field must not be the same in its every part, but must be so formed as to allow the inductor to move through force of varying intensity.

This is fundamental, but unfortunately it renders impossible the designing of a machine to generate a perfectly constant or uniform current in one direction.

Referring to unipolar dynamos, we may well study Mr. Tesla's design in the specification of his U. S. patent No. 447,921, issued March 10, 1891, which discloses a unipolar machine having a magnet core identical to the one shown by Mr. Balch, with one exception, which however renders the Tesla machine operative.

In Mr. Balch's machine the surface of the annular or disk-like poles is flat, thereby presenting a field of perfectly uniform strength to the inductor at all points in its travel; while the Tesla annular poles are corrugated or serrated or grooved radially, by means of which, the field is divided into a large number of radially defined portions, contiguous ones being alternately of lesser and greater intensity. If paraphrasing is allowed, we may say that the moving inductor passing through these portions will so cut the magnetic lines as to alter by its motion the number of lines that pass through said inductor.

Now, if Mr. Balch will make serrations or grooves in the surfaces of his poles in a direction similar to the length of his inductor, he will undoubtedly generate currents therein.

I may however hold up before him the horrible fate he would encounter should he attempt to "make, use or sell" his machine modified as above, as it would appear to infringe the aforementioned patent to Mr. Tesla, the first claim of which, recites:—"The combination, in an annular field of force formed by opposing polar faces with radial grooves or serrations, and with said poles, of a connected series of radial conductors, so disposed with relation to the serrations that while one portion of the radial conductors is passing between the strongest parts of the field, on the points where the two poles most nearly approach, the adjacent or intermediate conductors will pass through the weakest parts of the field, or the points where the two poles are most remote, as set forth."

This claim is an exceedingly broad one, and such claims are not always found to be tenable by the courts, which after all are the most practical appraisers of the work of the inventor.

HENRY GUSTAVE ROGERS.

CLINTON, Conn., September 30, 1892.

SOCIETY AND CLUB NOTES.

THE NEW YORK ELECTRICAL SOCIETY.

WE have received the following announcement from Mr. Geo. H. Guy, secretary of the New York Electrical Society, Room 812, 203 Broadway, N. Y.

Following its usual custom the society proposes this year to continue its course of lectures, which will comprise fifteen in all, embracing the following subjects, and with the names of the lecturers, where their services thus far have been provided for:

1. The Arc Light (with experiments). By Mr. R. S. Dobbie. 2. The Telephone, (experimental). By Mr. J. J. Carty, electrician Metropolitan Telephone Co., New York City; and Mr. F. A. Pickernell, engineer American Tel. & Tel. Co. (Long Distance Co.) 3. How to Lay Out and Wire an Isolated Lighting Plant, and How to Operate It. By Mr. Aug. Noll, superintendent New York Electric Equipment Company. 4. Primary Batteries, (with exhibit of various batteries). By Mr. G. d'Infreville, late electrician Western Union Tel. Co. 5. Electricity in Medicine, (experimental). By Dr. William J. Morton. 6. The Progress of the Year. By Mr. Joseph Wetzler. 7. What Europe is Doing in Electricity. By Prof. F. B. Crocker. 8. The Magnetic Field. By Prof. E. J. Houston. 9. Insulation and Surface Leakage, (with experiments). By Dr. J. B. Williams. 10. Electric Heating, (with experiments.) 11. The Storage Battery. 12. The Continuous Current Motor, (with experiments.) 13. The Alternating Current Motor, (with exhibit.) 14. Electric Railways. 15. The Incandescent Light.

In order to attain the full measure of its usefulness, and to encourage beginners to associate themselves with it, the society makes no distinction whatever in the grade of its membership, to which any person interested in its work is eligible without examination of any kind as to his knowledge of the subject. An invitation is extended to all amateurs, students, artisans, manufactures and others interested in the progress of electricity to join the society and aid it in its work.

The dates and meeting place for the lectures will be announced in due season. Admission, which is free, can only be gained by non-transferable tickets which can be had on application to the secretary. The annual dues to the society are $3 00, and the secretary will furnish blank forms of application for membership on request.

THE 146th meeting of the Society will take place at Columbia Hall on Wednesday, Oct. 19.

PROF. F. B. CROCKER will deliver an address entitled "What Europe is Doing in Electricity," in which he will describe the numerous electrical establishments visited by him during a recent trip abroad.

PROF. CROCKER will point out specially the differences between our methods and those in vogue abroad, illustrating his remarks by photographs which will be exhibited.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED OCTOBER 3, 1892.

Accumulators :—

Storage Battery, E. R. Knowles, Brooklyn, N. Y., 483,562. Filed Oct. 15, 1891.

The element consists of separated elementary cells perforated and filled with absorptive material, and spacing strips separating the cells; the whole being confined by bands and rivets.

Storage Battery, E. R. Knowles, Brooklyn, N. Y., 483,563. Filed Oct. 15, 1891.

Employs an electrode consisting of trays arranged one on top of another and connected by a strip.

Alarms and Signals :—

Electric Burglar Alarm, H. T. Wilson, Louisville, Ky., 483,625. Filed June 9, 1892.

Electric Burglar Alarm, A. Stromberg, Chicago, Ill., 483,728. Filed Mar. 15, 1892.

Burglar Alarm Contact, N. M. Hopkins, Washington, D. C., 483,844. Filed May 9, 1892.

Conductors, Conduits, and Insulators :—

Process of Making Artificial Mica Sheets for Electrical Insulation, A. H. S. Dyer, Schenectady, N. Y., 483,646. Filed June 1, 1892.

An arrangement by which artificial plates are formed of small broken scales of mica.

Molding Mica Forms for Electrical Insulators, C. W. Jefferson, 483,653, Schenectady, N. Y., Filed June 1, 1892.

Closed Conduit for Electric Railways, W. G. Creighton, Norwood Park, Ill., 483,761. Filed Feb. 6, 1892.

A combined tube and rail having an angular slot for the passage of the traveling contact.

Insulator, A. P. Seymour, Syracuse, N. Y., 483,771, Filed March 5, 1892.

Consists of a solid block of porcelain provided on its periphery at one end with two lugs on opposite sides of the line in which the wire lies when passed beneath both the lugs.

Dynamos and Motors:—

Motor Mounting for Electrically Driven Fans, A. L. Riker, New York, 483,582. Filed Dec. 22, 1891.

Consists in an arrangement such that the shaft and magnet frame are each removable without disturbing the other.

Armature for Dynamos and Motors, E. Thomson, Swampscott, Mass., 483 700. Filed Dec. 2, 1891.

Employs a core having one or more notches and filling plugs and having projections on its inner surface, and separable coils of such size and shape as to be cast through the notches and over the projections between which they are held in place.

Armature for Motors and Generators N. C. Bassett, Lynn, Mass., 483,708. Filed Feb. 27, 1891.

Employs an interior core, to which are attached surface sections extending out over the coils and meeting at the surface so as to complete the enclosed coils.

Armature Winding for Dynamo-Electric Machines, E. P. Warner, 483,729. Filed Sept. 30, 1889.

Employs coils symmetrically placed upon the armature with only two joints in the entire system of winding; the different coils being extended at one end to facilitate the connection with the commutator segments.

Commutator for Electric Machines, N. C. Bassett, Lynn, Mass., 483,732. Filed Aug. 26, 1891.

Employs a shell with the commutator segments arranged above the periphery and a number of individually adjustable clamping devices, each engaging with two or more segments.

Alternating Current Motor, W. Stanley, Jr., and J. F. Kelly, Pittsfield, Mass., 483,816. Filed Mar. 10, 1892.

Employs a condenser in shunt, with the motor of a capacity capable of neutralizing the self-induction of the motor.

Electric Locomotive, T. L. Willson, Brooklyn, N. Y., 483,822. Filed Aug. 25, 1891.

The combination of an armature shaft geared to the driving wheel, an armature loosely mounted on said shaft and having a recessed hub, and a friction clutch engaging between the shaft and the hub.

Galvanic and Thermo-Electric Batteries :—

Galvanic Battery, H. T. Johnson, New York. 483,651. Filed Dec. 10, 1891.

Has the exciting agent and the depolarizing agent arranged ultimately in horizontally disposed strata within the cup shaped positive electrode.

Thermo-Electric Battery, P. Giraud, Chantilly, France, 483,782. Filed Aug. 1, 1891.

Employs an electrode composed of antimony, zinc, cadmium and silicium.

Heating:—

Electrical Heater, A. E. Appleyard, Boston, Mass., 483,758. Filed Sept. 14, 1891.

Employs a resistance of carbon having wires connected to its ends and an externally exposed homogeneous waterproof insulating covering enclosing the sides and ends thereof.

Electrical Heater, A. E. Appleyard, Boston, Mass., 483,759. Filed Dec. 28, 1891.

Employs a water-tight casing enclosed in which is a resistance consisting of a strip of ribbon form, the sides being presented to the walls of the casing.

Electric Heater, F. B. Perkins and C. S. Jones, Toledo, O , 483,940. Filed April 1, 1892.

Employs an insulating cylinder fitting over the bottom aperature in the heating place and a conducting wire walled longitudinally upon the cylinder extending over its inner and upper faces.

Lamps and Appurtenances :

Adjustable Electric Light Hanger, H. L. Holt, Ellsworth, Me., 483,556. Filed Feb. 5, 1892.

Holder for Incandescent Lamps, E. P. Allam, Romford, Eng., 483,974. Filed Oct. 27, 1891.

Miscellaneous:—

Fire Extinguisher, Oscar J. Averell, New York, 483,522. Filed March 11, 1890.

A chemical fire extinguisher operated by electric current.

Electric Fan, E. B. Cutten, New York, 483,545. Filed May 22, 1891.

Comprises a base containing the motor, a vertical shaft projecting upward, a fan carried by the shaft and a connecting socket mounted at the top of the shaft.

Electromagnetic Mechanism for Operating Printing Presses, E. H. Korsmeyer, Kansas City, Mo., 483,564. Filed Sept. 5, 1891.

Claim 3 follows:

In a printing press the combination with a type bed and a movable platen of electromagnets and armatures for effecting the main movement of said platen and a supplemental electromagnet and armature suitably connected with said platen for effecting its final movement to produce the impression.

Electrolytic Diaphragm, A. J. Lehman, New York, N. Y., 483,692. Filed July 6, 1891.

Consists of a porous substance having its pores filled with an amorphous non-gelatinous precipitate; said precipitate being preserved in a moist state by treatment with a deliquescent salt.

Hygrometric Valve Controller, C. W. Rogers, Chicago, Ill., 483,725. Filed Dec. 24, 1891,

A hygrometric device adapted to close an electric circuit for the purpose of automatically controlling the valve.

Door-Lock Switch for Electric Lights, O. Green, Toronto, Canada, 483,739. Filed April 8, 1892.

Electro-Therapeutical Instrument, J. W. Molière, San Francisco, Cal., 483,745. Filed Sept. 14, 1891.

An electrostatic machine for physicians' use employing an air-tight case and an air blast apparatus for forcing air into the case.

Insulated Rivet, W. S. Hull, Sheffield, Ala., 483,806. Filed May 2, 1892.

Employs an insulation of asbestos.

Railways and Appliances :—

Trolley Catcher, J. J. Hoppes, Springfield, Ohio, 483,689. Filed Feb. 24, 1891.

Consists of a jointed or flexible trolley arm, a portion of which is adapted to assume an unusual position which will set in operation mechanism to withdraw the trolley arm from its normal position to one clear of the conductor.

Electric Railway, W. G. Murphy, Jr., Marysville, Cal., 483,856. Filed Sept. 30, 1891.

Employs a connector formed of two sliding bars, each carrying a grooved roller for making contact with the cable in the conduit, one bar raising the cable and the other depressing it.

Switches and Cut-Outs :—

Electric Switch, D. H. Armstrong, Long Island City, N. Y., 483,704. Filed June 11, 1892.

Comprises an insulating base, a centre post connected with the thumb-piece at the outer end and having a square inner end, a sleeve on said post and segmental cam on said sleeve, a contact spring connected with the main line in contact with the square end of the sleeve and two contact springs adapted to be moved in or out of circuit with the cam.

Electric Switch, A. Ekstrom, Lynn, Mass, 483,712. Filed Nov. 10, 1890.

Employs a contact maker and spindle with a fixed cam thereon and a reversely shaped non-rotating cam pressed into engagement with the fixed cam.

Electric Snap Switch, A. Ekstrom, Lynn, Mass , 483,713. Filed April 7, 1891.

Employs fixed contact surfaces and a reciprocating bridging contact, movable perpendicularly to said surfaces.

Electric Switch, H. T. Paiste, West Chester, Pa., 483,863. Filed May 14, 1891.

A quick brake switch whose action is independent of the rapidity of movement of the handle.

Telegraphs:—

Police Telegraph System, C. A. Rolfe, Chicago, Ill., 483,768. Filed May 6, 1892.

Provides means whereby any irregularity or neglect in the sending of a report can be readily detected by the officer in charge.

Telephones and Apparatus :—

Telephone Receiver, F. Gross, Montreal, Can., 483,718. Filed Jan. 18, 1892.

A rubber air cushion adapted to be placed about the mouth of a telephone receiver.

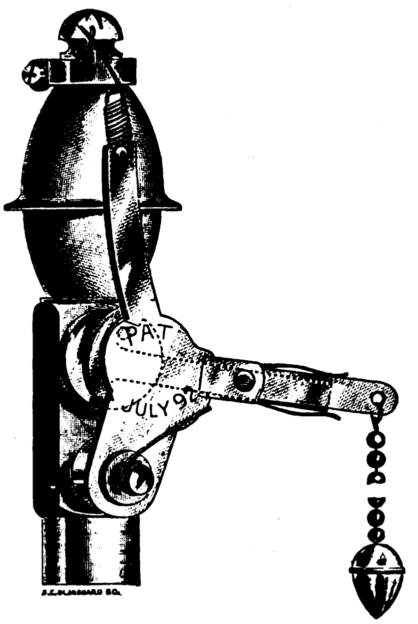
TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

Advertising is to trade what electricity is to traction—an investment that means economy and profit.

THE IONA SAFETY PENDANT BURNER.

We illustrate herewith the Iona safety pendant burner, which possesses several novel features. In this burner there is but one contact made in lighting and extinguishing the gas. This result is accomplished by the wire spring passing over the electrode on its return from the lighting pull, and on the off pull by a very ingenious arrangement of the valve cam, the electrode not being touched at all. The on and off pulls are decidedly different, and one can readily tell even in the dark whether the gas valve is open or closed. There is no possible danger of mistake on this point. These burners are made in the best possible manner, the valves being hand ground and always perfectly tight. The movements are simple and positive, and there is no ratchet or complicated spring to get out of order. This burner is being placed on the market by the Redding Electric Company, 41 Federal street, Boston, who have already received a number of large orders from the trade.



Iona Safety Pendant Burner.

THE GENERAL ELECTRIC COMPANY AT THE CLEVELAND CONVENTION.

The exhibit which the General Electiic Company will make at the Street Railway Convention promises to be of especial interest to street railway men. Among other things it will exhibit a magnificent new special car, which is probably the finest equipped streer car that has ever yet been constructed. This car will have a single truck equipped with two 15 h. p. W. P. 30 motors, regulated by the latest type series parallel controller. They will also exhibit a fine long car mounted on double trucks, equipped with W. P. double 25 h. p. motors, with both forms of control. The car will be equipped with measuring instruments, so that the economy of each method of control can be compared. These cars will be run upon the lines of the East Cleveland Railway Company, and the General Electric Company will furnish tickets to interested visitors.

At the hall will be shown a truck equipped with two 15 h. p. W. P. motors connected with the series parallel controller so that the operation of the motors can be clearly inspected. A dissected W. P. 30 motor will constitute part of the exhibit, clearly showing its great simplicity. Motors of the S. R. G., S. R. F. and Edison No. 16 types will also be shown. In addition a complete line of the new overhead parts introduced by the General Electric Company will be displayed, showing many new features.

Magnificent decorations of incandescent lamps will be made, not only around the hall, but also at the Hollenden Hotel, while a beautiful souvenir hand-book, containing very valuable information on the general operation of electric railways, as well as covering the important features of the General Electric Company's apparatus, will be taken away by all the street railway men there.

THE AHEARN ELECTRIC HEATER.

The electrical trade is well acquainted with the reputation of the Railway Equipment Company of Chicago, for energetically pushing the sale of the material it handles. This activity has in no department been more noticeable than in that of electric heating. Clearly seeing the tendency of the awakening interest in that subject, it obtained two years ago the control of an electric heater which, at the time, was the only practical device of that description made. Having placed hundreds of these heaters in all parts of the country, and having constant calls for an improved heater, and also heaters for other than car use, they investigated for nearly a year the merits of the Ahearn electric heater, and finding it an almost perfect device, they have obtained the entire rights for its manufacture and sale for the entire world. The company is about to issue an illustrated catalogue, showing the Ahearn heater in actual use, and in the meantime they are prepared to give facts and figures of actual results obtained by the use of this convenient and efficient heater. We understand that samples of the heaters are to be shown at the Street Railway Convention in Cleveland.

THE PARTRICK & CARTER COMPANY.

Messrs. Franklin S. Carter, Charles M. Wilkins and E. Ward Wilkins, trading as Partrick & Carter Co., have issued a profusely illustrated 180 page catalogue of their goods, chief among which are their annunciators. Bells, batteries, telegraphic instruments, medical apparatus, etc., also occupy conspicuous positions throughout the pamphlet.

The Partrick & Carter Co.'s needle annunciators are so extensively used and so well known that a detailed description is unnecessary. Within the last year they have added several new features and changed the set-back mechanism entirely. The advantages they claim for the new set-back or tripping mechanism are that it keeps all the needles free at all times on their pivots, and greatly simplifies this, the most troublesome part of all annunciators. The system of guest call and fire alarm has met with unqualified success and approval, and during the last few years they have been crowded with orders for annunciators, combined with these systems.

SPRAGUE ELEVATORS FOR THE NEW POSTAL BUILDING.

The Sprague Electric Elevator Co., 15 Wall street, this city, have closed a contract with the Postal Telegraph-Cable Co. for six Sprague electric elevators to be installed in their new fourteen-story buiding, at the corner of Broadway and Murray streets. Four of these elevators are for ordinary way service, and are to have a speed of 300 feet per minute. The other two are to be designated as "Express" elevators, and are to run at not less than 400 feet per minute under a live load of 1,800 pounds. They are to be operated from current generated by a special plant in the building, but will also be arranged so as to take current from the Edison street mains on Sundays and holidays, when the interior plant might not be running. This contract was awarded after the officers and architects of the Postal Telegraph Co. had given the recent installation at the Grand Hotel in this city a most careful and critical investigation.

AN "ENTERTAINING FEATURE."

Probably the most entertaining feature of the current number of the New York Electrical Engineer is a contribution by John Dennis, Jr., of the staff of the Rochester *Democrat and Chronicle*. It is a detailed description of the new auxiliary fire alarm system, invented by William L. Denio and installed by the Standard Electric Signal Company, of this city. The system is noted for the effectiveness, smoothness and noiselessness of its operation. Mr. Dennis' paper is a careful and exhaustive analysis of the methods of the system, which the reader is aided in understanding by a series of excellent cuts and engravings.—*Rochester* (*N. Y.*) *Herald.*

A BIG WESTINGHOUSE RAILWAY CONTRACT.

The largest contract ever placed at one time in the West was given out last week, when the Westinghouse Electric Manufacturing Company closed a contract with the Chicago City Railway Company for the complete equipment of 61 cars with their single-reduction type motor; also for four 300 h. p. generators for their cross-town lines.

THE CLOVERDALE, ALABAMA, ELECTRIC ROAD.

Mr. H. E. Heller, the secretary of the Cloverdale Land and Development Co., of Montgomery, Ala., writes us that the central section of their road was started on October 3, and that the other part will be in operation by the middle of the month, making a total of seven miles. The cars are equipped with the Thomson-Houston waterproof motor and series parallel controller, and run beautifully, handling 50 to 75 people per car all day long with the utmost satisfaction to the public.

ST. LOUIS NOTES.

The St. Louis Electrical Supply Co. are making a very attractive exhibit at the Exposition in St. Louis. They are showing a full line of Carpenter electric heating appliances, Packard lamps, some of which are of very large candle power, fine testing instruments and other electrical supplies and novelties. They have an electrified bucket of water in which coins of various denominations are dropped; then they politely invite unwary bystanders and the persistent small boy to help themselves—and the result is shocking.

The Municipal Electric Light Co., of St. Louis, show at the Exposition a striking illustration of transmission of power, a Thomson-Houston motor being operated from their circuit and running a Ft. Wayne incandescent generator, which lights up a large number of incandescent lamps, some of which are arranged in the form of a handsome signboard.

The Wagner Electric Mfg. Co., of St. Louis, make a fine display at the Exposition of their alternating and direct current motors and generators. They have a very ingenious electric fountain, the water for which is pumped by a motor operated by alternating current and which attracts a good deal of attention.

The Emerson Electric Mfg. Co. has an exhibit at the St. Louis Exposition of alternating current motors for fans and other work, and a full line of their other railroad, electric light and station specialties.

NEW ENGLAND NOTES.

The Corliss Steam Engine Company, of Providence, R. I., are at present building two engines for the Interstate Consolidated Rapid Transit Railway Company, of Kansas City, one of which is a single engine with cylinder 36-inch diameter by 60-inch stroke, and the other a tandem compound engine with cylinders 22-inch and 40-inch by 60-inch stroke. Six of their well-known Corliss patent vertical tubular boilers, each of 250 h. p., will accompany these engines. The Corliss Company have recently started the immense engine of 2,400 h. p., which they installed in the new factory of the Fall River Iron Works Company, and which has attracted wide attention owing to its magnitude. The engine is triple expansion and has six cylinders, two sets of three tandem, the dimensions of the cylinders being as follows, all with a stroke of 60 inch : Two high pressure, 23½-inch diameter ; two intermediate, 36½-inch diameter ; and two low pressure, 54-inch diameter. The fly-wheel is 28 feet in diameter, with a face measuring 15 feet 4 inches wide, from which a number of belts are driven. When steam was let into this monster, it started off just as smoothly as if it had been running for years.

The Whitney Electrical Instrument Company, of Boston, have left their old offices at 35 Hartford street, and will hereafter be found at 146 Franklin street. Mr. Harry Kellogg has again become identified with this company, and will hereafter have charge of the selling department. The factory of this company has also recently been removed from Manchester, N. H., to Pennacook, N. H., and they now have very largely increased facilities for the manufacture of their instruments which are daily growing in popularity, as reliable and at the same time extremely reasonable in price.

C. S. Knowles, of Boston, has recently put on the market a new compound, which he calls "American Chatterton Compound." As is well known, Chatterton compound has been extensively used abroad for insulating purposes, but hitherto has not been much used in this country. Mr. Knowles claims that his compound is approximately the same as the English—which has always had a high reputation—but is considerably purer and better. He has already supplied a large quantity of this material, and it has given the best of satisfaction.

The American Electrical Works, of Providence, R. I., celebrate every public and national holiday by issuing some proclamation or brochure appropriate to the occasion. This week they have sent out to all their friends a tasteful reprint in red and black of the chart or globus of Martin Behaim, of 1492, with a star to indicate were the American Electrical Works would have been found had Columbus steered north instead of allowing his attention to be distracted by a flight of Rhode Island clams about to winter at Saint Augustine.

The Electric Railway Engineering Company is the name of a new company just started with headquarters at room 88, 180 Summer street, Boston. They have secured a corps of competent engineers, and are prepared to do general engineering for the designing and construction of power plants, for electric railway, lighting and other stations, and will also pay attention to steam plants and water-powers. Mr. J. F. McGowan and Mr. A. U. Jaasted are connected with the company, both of whom have had a long and varied experience in general electrical engineering, and are well adapted to manage successfully the affairs of the company which they have just organized.

Mr. Maybin W. Brown, well known in electrical circles, as formerly president of the Eastern Electric Supply and Construction Company, has gone into the supply business for himself, under the title of M. W. Brown & Co., with headquarters at 620 Atlantic avenue, Boston. Mr. Brown has a large acquaintance amongst the electric fraternity, and has, we believe, secured a number of valuable agencies.

Mr. F. H. Underwood, president of the Underwood Manufacturing Company, of Tolland, Conn., will hereafter make his headquarters at 126 Pearl street, the Eastern office of the company, and will hereafter take entire charge of the New England business himself. Mr. Underwood will be glad to see all his old friends at his new address.

This office was favored with calls from several old friends during the past week, amongst whom were Messrs. Ralph L. Shainwald and Frank S. De Ronde, of the Standard Paint Company, of New York ; Mr. Frank Harrington, of New York, and Mr. Charles Dutton, of New York.

WASHINGTON NOTES.

The Hanson Battery, Light & Power Co. have been remarkably successful in Washington with their primary battery on a great variety of work, and in order that the Hanson Company may devote itself to its own work of supplying the demand all over the country, a local company has been formed which will take over and develop the large local business. Mr. Aldrich's brilliant demonstration with his launch on the Potomac has brought a flood of inquiries on the subject.

The Bliss Engineering Company, of Washington, D. C., are now wiring for two hundred and fifty lights in a large new office building located at Ninth and F streets, and the private residence of Chris. Heurich for two hunded and fifty incandescent lights, eighty burglar alarm outlets and twenty-four automatic gas burners ; also the residence of Rev. Chas. Stakley.

NEW YORK STATE NOTES.

Cohoes, N. Y.—The central lighting station has recently placed two new dynamos in line to meet increased demands for lighting. The new club house of the Cohoes wheelmen, the city recorder's offices and the private residences of J. W. Hines and George R. Wilson are all to be equipped with incandescent lamps.

The new alumni building of the Rensellaer Polytechnic Institute is being wired for incandescent lighting, the current at present to be supplied by the local electric lighting company, but the wiring is arranged especially for an isolated plant, which the building committee expect to put in at some future time.

West Troy, N. Y.—The citizens will have submitted to them for voting upon a proposition to tax the village for $6,500 additional in order to erect a new station more central than at present and to provide for such additional facilities as may be required to add to the illumination of the village streets.

The Troy Orphan Asylum, now in process of erection on Spring avenue, is to have a complete system of electric bells and lighting from an isolated plant. The large clothing store of W. & M. Gross has also been completely wired for an isolated plant, and is now in full operation.

Mechanicville, N. Y.—The poles for the new system of lighting the town are now being distributed through the streets, and the work may at last be considered fairly under way, as sufficient business has been contracted for to make the plant a success.

Mr. W. J. Morrison, Kirk Building, Syracuse, N. Y., representing the Fort Wayne Electric Co., reports business as first-class. He has just closed a contract for 750 incandescents for Springville, N. Y.

Mr. W. H. Brenner.—The friends of Mr. W. H. Brenner, formerly with the Edison Company in Canada, will be pleased to hear that he has been recently appointed electrical engineer to the Montreal Street Railway Company.

NEW YORK NOTES.

Mr. A. de Castro, 31–33 Pine street, New York, issues a preliminary circular of the Anglo-American Union, Ltd., London and New York. Mr. de Castro, as engineer and general manager, announces the readiness of the company to supply telephones and telephonic apparatus for export only. The capital stock is stated as £1,000,000. The circular of the company includes a series of illustrations of telephones and apparatus embracing several familiar American types. Further information of the progress of the Anglo-American Union, Ltd., will be interesting to exporters of telephones.

Mr. Hammond, of the Supply Manufacturing Co., Pittsburgh, Pa., was in New York, last week. He reported that he had sold in the last 10 days more of the commutators which his company makes than can be turned out in two months. Many sales are directly traceable to The Electrical Engineer, one alone amounting to $1,000.

Col. W. E. Sheldon, treasurer of the Fitchburg Engine Co., has just closed a contract with the Chemical Paper Co. of Holyoke, Mass., for seven 75 h. p. engines. This certainly speaks well for the persuasive abilities of the salesman, or the good qualities of the engine; perhaps both.

WESTERN NOTES.

Taylor, Goodhue & Ames, 827 Monadnock Building, have taken the exclusive agency for the entire output of the Nutting Electric Manufacturing Co.'s arc lamp for both direct and alternating circuits, street railway, power and series arc service. This lamp is of very remarkable and unique construction; its feeding mechanism contains no clutches, clockwork, gears or other mechanical feed, this being regulated by the heating effect of a shunt circuit. There is a pin whose ends are embedded in a disc of wax, which it permits to revolve and feed the lamp as the heat of the pin varies. This lamp has received exhaustive tests at the hands of Mr. Carl K. MacFadden, electric light inspector of the Chicago and North Western Railway Co., and it is claimed possesses meritorious features not secured by any other construction.

Mr. C. B. Osgood, one of the well-known gentlemen in electrical circles, in Chicago, formerly connected with the Westinghouse Company, as selling representative for the railway department, has associated himself with the Premier Steel Co. of Indianapolis, and has secured the general sales agency for the United States for the Premier electric elevator and also for the hydraulic and steam elevators manufactured by this company. Mr. Osgood has had many years' experience in the elevator business, and is thoroughly posted in all particulars of this branch of work, eminently fitting him for the new enterprise he has undertaken. Mr. Osgood has taken a handsome suite of offices at 319 and 320 Manhattan Building, where he will appreciate a call from his many friends.

The Rice Machinery Co. are now permanently located at their new quarters, 166–174 South Clinton street, having removed from their old quarters, 63 and 65 South Canal street, Oct. 1st. This concern are now making a specialty of complete shafting equipments for electrical generating plants, and with the increased facilities and heavy machine tools recently added, are in a position to handle contracts of any size. They are representatives and general agents for the Dodge Manufacturing Company, of Mishawaka, Ind., and are pushing the sale of the Dodge patent split disc friction clutch pulleys and cut-off couplings, also the Dodge special dynamo pulleys.

The Electrical Supply Co. are drawing crowds every afternoon by their Mongolian and Celestial exhibit in their handsome store on Michigan avenue, where can be seen a Chinese laundry under full swing in which all the heating is done by means of electricity, everything being in charge of Chinamen, who handle the invisible fluid as if they enjoyed it. The progressive enterprise of this company is astounding, and they always let people know when they have anything good.

Mr. A. A. Forman, superintendent of the Iron Mountain Electric Co., of Iron Mountain, Mich., was among the Chicago visitors last week. Mr. Forman has recently been making additions to their plant, and among other machinery has installed one of Stillwell's feed water heaters, which he purchased through seeing the announcement in the advertising columns of The Electrical Engineer.

Mr. F. E. Drake, selling representative of the Standard Electric Co., 313–317 South Canal street, reports that his company are exceedingly busy filling the large contracts recently secured by them. The Standard system of arc lighting is becoming very popular.

Clark & Marshall, 413 Rookery, Chicago, are handling a line of fine specialties, including Boston incandescent lamps, Arnold flexible brackets, Cope come-alongs and Dow adjustable hangers, and are meeting with good success with all of them.

The Railway Equipment Co., Pullman Building, Chicago, are pushed to their utmost capacity filling orders for electric railway supplies of all kinds. The line of Ahearn electric heating appliances, which they are placing on the market, are also meeting with a very extensive demand. Their factory at Mansfield, Ohio, is now well under way to supply the call for these goods and to keep up with the immense trade they are doing in their patented railway specialties, of which they control a large number of novel and valuable specialties. Mr. Adams, of the company, is now at the factory pushing matters there and looking after the turning out of the goods.

The Central Electric Company are about to handle the Iona porcelain rosette. This rosette was illustrated in The Electrical Engineer a short time ago. The cap is removable, and is replaced by a bayonet catch, and does not require a screwdriver. The pin and bracket mill of the Central Electric Company is working full force and turning out thousands of pins and brackets. These goods are made from second growth white oak, sawed with the grain, making them tough and durable. The Central Electric Company are selling large quantities of Acme lead cables, made by the Okonite Company, and carry it in stock to fill requirements.

The Sunbeam Incandescent Lamp Co. is probably the first to make any radical departure from the familiar "pear" shape form of bulb. Their "Acorn Sunbeam" is meeting with a large sale for decorative and other purposes. It has the same "long life" and efficient essentials that have for so long distinguished the regular Sunbeam lamps.

The Hay-Horn Manufacturing Co. are getting a great many orders both from the East and West for their well-known bells. These bells, they claim, are the cheapest, simplest, and most efficient made. They have just issued a handsome new price list of these goods, which show the various forms and some weighty testimonials.

Wm. Hood & Co., 239 La Salle street, managers of the Chicago office of the Electric Manufacturing Co., of Oconto, Wis., have shipped out a large number of orders for Brilliant incandescent lamps during the past few weeks. These lamps, they state, are giving good satisfaction and repeat orders are numerous.

J. H. Siegrist, Jr., & Co., room 18 Laclede Building, St. Louis, have sold to the Cass Ave. and Fair Grounds Railway Co. a 250 h. p. Ideal engine; to Smith & Davis Manufacturing Co., St. Louis, a 100 h. p. Ideal, and to the Columbia, Ill., Electric Light Co., a 70 h. p. Ideal.

Mr. W. W. Borst, superintendent of the Denver Consolidated Electric Co., recently spent several days in St. Louis inspecting the enormous electric lighting and railway plants in that city. Mr. Borst was much pleased with what he saw while there.

The Buckeye Electric Co.'s representative at Chicago says that "Not a wave of trouble rolls across his peaceful breast," with one exception, namely, the inability of his company to keep even with orders, which swoop in on him from all directions.

Mr. W. R. B. Wilcox, whose articles on electric heating attracted considerable attention recently, is going East, to Boston, where he intends taking a complete course in architecture at the Massachusetts Institute of Technology.

The Great Western Electric Supply Co. are busy in all branches of general supplies for lighting and power work. They are receiving orders for a good many generators and Detroit motors for which they are agents.

Mr. J. L. Barclay has returned to Chicago after an absence of three months which he spent with his family among the principal Eastern summer resorts, where he has been storing up ozone and energy.

Mr. Carl K. MacFadden, electric light inspector of the Chicago Northwestern Railway Co., is putting in quite an extensive depot lighting plant which he expects to be a model when completed.

The Simpson Electric Mfg. Co., 39–41 West Washington street, are putting on the market a new 10-light incandescent dynamo on which they expect to have a large run.

The Rabich Fan and Motor Manufacturing Co. has been incorporated at East St. Louis with a capital stock of $10,000, by Bruno B. Herrman, Wm. Rabich and G. Karne.

Mr. Dillworth Richardson, general manager of the Carpenter Electric Heating and Mfg. Co., of St. Paul, was among the recent visitors to the World's Fair city.

Sargent & Lundy, electrical engineers, Monadnock Building, Chicago, are busily engaged finishing up several important contracts that they have had on hand.

Mr. Harry Howell has accepted a position as cashier and bookkeeper with Wm. Hood & Co., managers of Chicago office of the Electric Manufacturing Co.

The Electric Appliance Co. report great activity in all lines of their business. They are working overtime with a largely increased force, and are only enabled to keep up with their orders with great difficulty. They also seem to be crowding the factories which they represent to their utmost. The Elkhart transformer factory is working day and night. The Packard Lamp Company are crowded almost beyond their capacity, and the Paranite people are doubling their force.

The Knapp Electrical Works are having quite a run on their specialties this month, and business in general electrical supplies is also exceedingly active. Safety wire appears to be quite a favorite and the orders for Perkins lamps are large. They are doing a steady increasing business all the time and the outlook is very bright.

Mr. Geo. Meeker, manager of the Chicago office of the New York Insulated Wire Co., is a busy man these days. The large contract secured by this company for the wire at the World's Fair is being rapidly filled, and Grimshaw wires and cables are receiving their full measure of attention.

Mr. H. H. Humphreys, who for some time was the representative of the Edison Electric Co., in St. Louis, has now opened up an office at No. 209 Globe-Democrat Building, in that city, and is representing the Western Electric Co.

PHILADELPHIA NOTES.

The Camden, N. J., Electric Railway.—For some years past the Camden Horse Railroad Co., of Camden, N. J., have been operating their electric cars with power rented from the Camden Electric Light Co. They concluded, finally, to put in their own station, and after a thorough investigation, placed an order with Messrs. M. R. Muckle, Jr., & Co. for two 12-inch and 20 x 12 inch Westinghouse compound engines to be run under 125 lbs. steam pressure and with a condenser. The station is not yet completed, but early one morning last week the large engine at the electric light station broke down just at the moment when the relay engine was being overhauled and was consequently not ready for duty. The new station had only had steam raised for the first time the day before, but fortunately one of the new generators was standing belted to one of the engines, and hasty connections were made to the line and the engine and the dynamo started to see if anything could be done. The result was so entirely satisfactory that after running two days on the single engine and dynamo it was decided to put in operation at once the extension of the line to Merchantville, which up to this time had never had a car over it. This loaded the one engine up pretty thoroughly, the ammeter reading as high as 210 amperes at times, so that all hands were rather anxious lest something should give way. After a consultation it was decided to abandon the electric light station altogether and the old generator was accordingly removed from that building to the new station, and now both engines and dynamos are running and handling the work smoothly and satisfactorily. This means that the finishing of the station, connecting up of the condenser, etc., will have to be done between two and five o'clock in the mornings, since no stop can be made on the road. The improvement in the service has been immediate and marked, the voltage being well maintained at all points of the line.

Warren, Webster & Co., 491 North 3d street, Philadelphia, Pa., sole licensees for the Williames vacuum system of steam heating, without back pressure upon the engine; proprietors and manufacturers of the Webster vacuum feed-water heater and purifier, report the following orders during the past month of September:

Enterprise Machine Co., Minneapolis, Minn.; Burtis, Patterson Sargent Paint Co., Cleveland, Ohio; Oatman Bros., Dundee, Ill.; Armour & Co., Chicago, Ill.; Morrison-Plummer Co., Chicago, Ill.; Racine Hardware Co., Racine, Wis.; National Casket Co., Hoboken, N. J.; E. Z. Wallower, Joplin, Mo.; Republic Iron Works, Pittsburgh, Pa.; American Hosiery Co., New Britain, Conn., Escanaba Lighting Co., Escanaba, Mich.; Union Wire Mattress Co., Chicago, Ill., Wilson Distillery Co., Highspire, Pa.; Watsontown Boot and Shoe Co., Watsontown, Pa., United States Iron and Tin Plate Co., Demmler, Pa.; Germantown Spinning Co., Germantown, Philadelphia, Pa.; Western Electric Co., Chicago, Ill.; The Swift Manufacturing Co., Columbus, Ga.; Swift & Co., South Omaha, Neb.; Swift & Co., Chicago, Ill.; Chas. T. Bainbridge's Sons, Brooklyn, N. Y.; Bamford Bros., Paterson, N. J.; H. P. Nail Co., Cleveland, Ohio; Pencoyd Iron Works, Pencoyd, Pa.; Mechanical Fabric Co., Providence, R. I.; Société Anonyme, Antwerp, Belgium; Jonathan Clark Building, Chicago, Ill.; Knight & Jillson, Indianapolis, Ind.; Detroit Sheet Metal and Brass Works, Detroit, Mich.; Smith Building, Chicago, Ill.; The Wm. Cramp & Sons Ship and Engine Building Co., Philadelphia, Pa.

They have just issued a new catalogue, and state that they will visit plants at their expense, and also furnish their apparatus upon trial.

The Reading Railroad Company's Terminal Station.—Of isolated contracts, probably none has been let in the last few years of the importance and general character of that for the Reading Terminal Railroad Company's new station at Philadelphia. The whole of this work has been in charge of Messrs. Wilson Bros. & Co., engineers and architects, and the specifications which they issued for the plant were remarkable for their thoroughness and strict attention to detail. The exact amount of the various bids is, of course, not made public, but there is little doubt that they were all in the neighborhood of sixty thousand dollars. The plant calls for the installation of ten 30-light dynamos and 270 arc lamps to be driven by five compound engines, each driving two dynamos. The whole of the work from the station for about three-quarters of a mile out is to be laid in conduit underneath the ballast on the road-bed so that no wires shall be above the surface. The lamps are all so divided upon the circuits that 5 out of the 9 circuits may be disabled without extinguishing the total light at any point. The competition for this plant was very close, but was finally secured by the Western Electric Co. of Chicago, who will use for the purpose their "high tension" arc system. The order for the engines and steam piping for the plant has been placed with Messrs. M. R. Muckle, Jr., & Co., who will install five 10 inch and 18 inch by 10 inch Westinghouse compound engines. The contract calls for the work to be completed within sixty days, and this plant will certainly take rank as one of the finest in the country.

Mr. G. H. Fisher, Philadelphia agent for Chas. A. Schieren & Co., says there was never such a demand for their "Perforated" electric leather belting as at the present time. During the past three months business has increased over 25 per cent. over the same months of 1891. Mr. Fisher has recently collected quite a number of valuable testimonials from those using Schieren's belting, one of which we publish below.

Altoona Manufacturing Co. Altoona, Pa., Oct. 1, 1892.

Charles A. Schieren & Co.
226 North 3d street.

Gents.—I have the honor of acknowledging your esteemed favor of the 15th ult., which I have now before me and carefully note contents, and in reply would say that we are very happy indeed to inform you that the six 15-inch double perforated endless belts which we purchased from you for use at the Altoona City Passenger Railway power house, and which have been in constant use for about one year, have given entire satisfaction in every respect and continue to run without sign of distress.

Yours truly,
M. A. Green.

The Supply Manufacturing Co., of Pittsburgh, Pa., will be ably represented at the Cleveland convention by its vice-president, Mr. R. R. Hammond. It will have a fine display of commutators of which it makes a specialty. Although not a young company, it has recently been reorganized with live and energetic men at the head who are bound to make a success of anything which they undertake. This is proven by the enormous increase made in their business during the past few months, which is compelling them to move into much larger quarters on Water street. Their new president, Mr. G. R. Stuart, is a man of wide business experience, having been for over nine years interested in the natural gas industry as president of the Saltsburg Gas Co. He is a civil engineer by profession.

The Fort Wayne Electric Co. have sold through their Philadelphia agent, Mr. G. A. Wilbur, a 650 incandescent light plant to the Frederick, Md., Electric Light and Power Co.; one 60-light Wood arc plant complete to the borough of Middletown, Pa.; one 25-light Wood arc plant to Walker & Kepler, for the county prison, and an additional 60-light Wood arc dynamo to the Suburban Electric Light Co. of Tacony, Pa.

J. L. Hayes & Co., of Pittsburgh, have opened an electrical repair and work shop at 830 Liberty street over the Robins Electric Co.'s store. They will make a specialty of the rewinding of armatures, repairing of motors and dynamos, model making and experimental work. Mr. John J. Fisher, foreman of the shop, is a thorough mechanic, and has been connected with the Westinghouse Co. for several years.

Mr. J. Stanford Brown, one of the best-known consulting electrical engineers in this part of the country has, in addition to his office in New York, opened a branch at the corner of Cooper's Creek and Federal streets, Camden, N. J.

The Commonwealth Electric Co. have the contract for wiring the Lafayette Hotel for 200 incandescent lights. They will also refinish all chandeliers and put in a large number of combination fixtures.

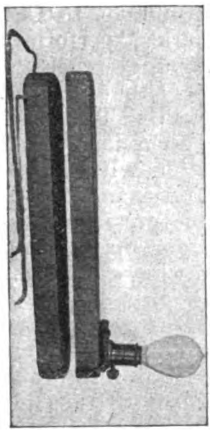
Mr. J. W. Parker has sold a 300 h. p. Ball automatic cut-off engine to the North Hudson Elevated Railway Co., of Hoboken, N. J., making the third engine of this size placed in this station within five months.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

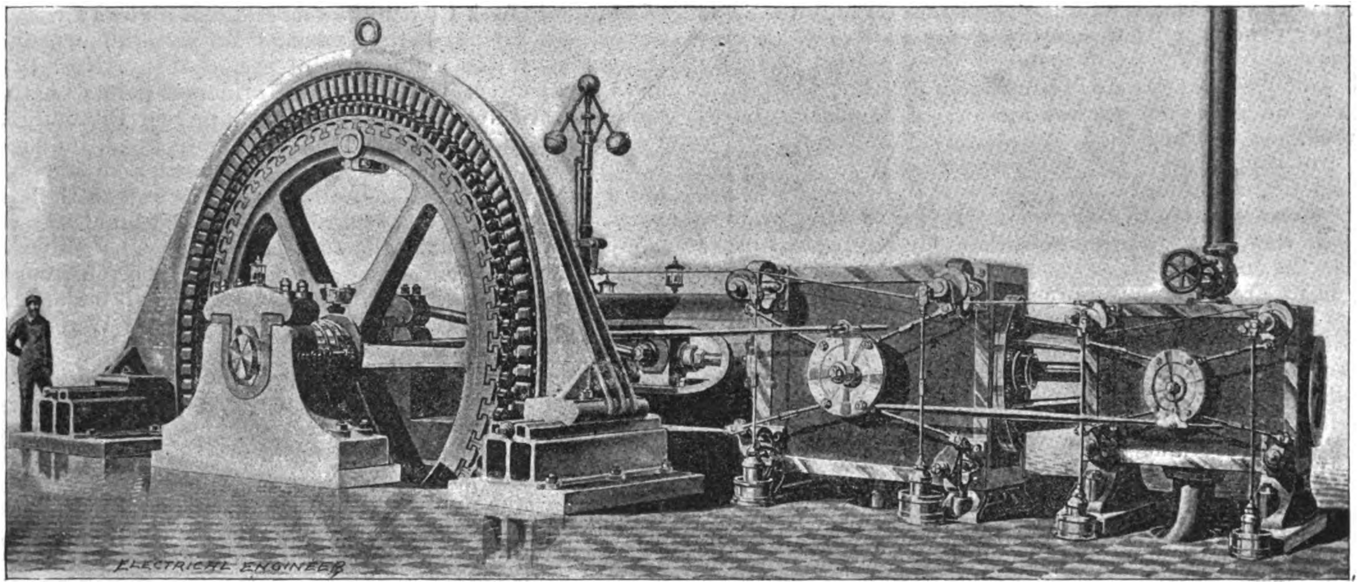
THE
Electrical Engineer.

VOL. XIV. OCTOBER 26, 1892. No. 234.

THE NEW 500 H. P. DIRECT CONNECTED WESTINGHOUSE ALTERNATOR OF THE NARRAGANSETT ELECTRIC LIGHT CO.'S STATION, AT PROVIDENCE, R. I.



LIVING in a city celebrated for its enterprise, Mr. Marsden J. Perry, vice-president and general manager of the Narragansett Electric Light Co., of Providence, R. I., has long since earned the reputation of having one of the best equipped and best operated electric central stations in the country. The success achieved may fairly be claimed to be due to Mr. Perry's policy of having nothing but the highest quality of men and material in and about his station, with the result that the company has found its business constantly increasing and calling for additional facilities. When, some time ago, the need for increased alternating apparatus became apparent, Mr. Perry, who had long been an advocate of the slow speed Corliss engine, resolved to adhere to this type of engine, but to go a step further and gain still greater economy in fuel consumption and space by the adoption of direct connected dynamos in place of the belt with countershaft. The success already achieved with direct connected machines in continuous current work here and abroad encouraged him in the adoption of a like plan for alternating current work with the result that an order was given to the Westinghouse Electric and Manufacturing Co. for a 500 h. p. alternate current generator, to operate at 2,200 volts.



NEW 500 H. P. DIRECT CONNECTED ALTERNATOR, NARRAGANSETT ELECTRIC LIGHT CO., PROVIDENCE, R. I.

The accompanying illustration is made from a photograph of the generator now being erected by the Westinghouse Company in the Narragansett Company's station at Providence. The machine is of the internal-multipolar type, built to meet exacting conditions of speed and regulation, and embodying the result of years of experience and experiment on the part of the Westinghouse engineers. As shown, the dynamo is coupled direct to a Reynolds-Corliss compound engine of 48-inch stroke, built in accordance with the latest designs, expressly for this installation, by the E. P. Allis Company, of Milwaukee, and now being erected under the immediate direction of Messrs. Remington & Henthorn, resident engineers for the Narragansett Company.

The generator, complete without the engine, weighs about 60 tons, and measures over 20 feet in diameter between the extreme edges of its circular field. On the armature there are over one thousand pounds of copper, while nearly five miles of wire are used for the field winding.

In order to comply with the Westinghouse new standard of 7,200 alternations, and at the same time run at the speed for which the engine was designed, viz., 90 revolutions per minute, the armature was constructed with a diameter of 16 feet. It is built up of wrought iron E-shaped sheets, bolted together and then fitted into what is practically the rim of a heavy cast iron fly-wheel. The projecting teeth of the armature are T-shaped and numerically equal to the pole-pieces of the field. Each tooth is surrounded by a simple lathe-wound coil, which, having been pressed into shape, is held rigidly in place by insulated strips driven between the coils and beneath the "T" edges.

The advantages of this armature, which is a type peculiar to the Westinghouse Company, are so noticeable as to be worthy of special remark. They are: The high insulation attainable in machine-wound coils, which in this machine has been made safe for 20,000 volts; the ease with which any single coil may be replaced without disturbing the others, and at almost no expense; the immunity from accident in case of overload or abnormal heating of the conductors, as no coil or wire can break loose and abrade insulation, or catch in the pole-pieces of the field; the small air space, only ⅜ of an inch, between the face of the pole-pieces and the surface of the armature, whereby the resistance of the magnetic circuits is greatly reduced, and the efficiency of the machine increased. To this must be added the freedom from liability to accident in handling, due to the entire absence of wires on the surface of the armature, and the increased ventilation secured by the use of a hollow armature and the large percentage of conductors exposed to the air—hence increased current capacity, with consequent higher efficiency.

The field pieces are lathe wound on bobbins, and then bolted into place on the pole-pieces. The winding is a simple one, all regulating and compensating being done by variation in the amount of exciting current, which is supplied from a separate dynamo.

In order to maintain a constant potential at the brushes of any generator, it is necessary to vary the field excitation when the load varies. The fluctuation of current in the fields of this machine is secured by the use of two transformers, which are placed diametrically opposite on the hub of the armature. These transformers are in multiple-series with the main circuit and their secondaries are connected with a commutator on the shaft. The rectified current thus derived will vary with the load of the generator, for if the load is increased there will be an additional flow of current on the main and a drop in the potential of the generator; the increased current thus introduced in the primary of the transformers will of necessity increase the secondary, *i. e.*, the rectified current. This last-mentioned current is used to partially excite the fields of the exciter, which, under the conditions stated, will have its E. M. F. raised, and hence send a larger current through the fields of the generator itself, causing a rise in its voltage and thus counteracting the drop due to the increased load. By this unique arrangement a comparatively easy, and yet at the same time very perfect method of regulation is secured.

The commutator and collecting rings, 28 inches in diameter, are placed side by side on the armature shaft, and so constructed that any one commutator segment, or a single ring, may be removed without disturbing any other than the one selected.

There are four sets of brushes, two for the rectified and two for the alternating current. They are supported from rods 90 degrees apart, projecting from a brush holder (not seen in the engraving), which rests on a base of its own, and, though encircling the shaft, is entirely independent of it.

Perhaps as valuable a feature of the generator as any is the simple yet satisfactory arrangement for separating the field and armature for purposes of cleaning, repairing, etc. The entire field is supported just below its mid-points upon two slides, running parallel to the shaft; by means of tension screws the whole field can be moved along the slides until completely withdrawn from the armature, thus giving easy access to any part of the machine. The generator, as stated above, is built to give 373,000 watts, 500 electrical horse power, at 2,200 volts potential, and has a guaranteed efficiency of 92 per cent.

A ST. LOUIS ELECTRIC CLUB.

STEPS toward the permanent organization of an electric club were taken at the last meeting of electricians at the Mercantile Club, of St. Louis. A committee of 10 was appointed to draw up a constitution and by-laws to be voted upon at the next meeting, which will be held on the second Friday in November.

NEW YORK—CHICAGO.—THE OPENING OF THE LONGEST TELEPHONE LINE IN THE WORLD.

THOROUGHLY delightful was the reception awaiting those favored with the American Telegraph and Telephone Company's invitation to attend the formal opening of the new telephone line between this city and Chicago, on October 18. Forty-two receivers were placed about the room and the guests listened to music, recitations and conversations. The exercises opened with the transmission to Chicago of "America," performed on a cornet, and its repetition immediately afterward from the other end of the line. Mr. John E. Hudson, president of the American Bell Telephone Co., and of the Long-Distance Company, then introduced Mayor Grant, who held a short conversation with Mayor Washburn, of Chicago, after which Prof. Alexander Graham Bell, who honored the occasion by his presence, conversed with Mr. William H. Hubbard, one of his early associates in the telephone enterprise, and who was at the Chicago end of the line.

Notwithstanding the fact that 42 receivers were included in the circuit, the articulation was perfectly clear and distinct, thus demonstrating the power of the transmitters and the admirable proportions and arrangement of the line circuit.

The long-distance telephone line between New York and Chicago extends 950 miles from the main office of the American Telephone and Telegraph Co., No. 18 Cortlandt street, New York City, by the most direct highway routes across New Jersey, Pennsylvania, Ohio and Indiana, and terminates at the main office of the company, Nos. 105, 107 Quincy street, Chicago. The principal points on the main line are Newark, N. J., Harrisburg and Pittsburgh, Pa., Cleveland and Toledo, Ohio and South Bend, Indiana.

In the Eastern States connecting lines reach all important points from Portland, Maine, on the east to Buffalo north and Washington, south. In the West branches are completed, or substantially so, from Chicago, to Milwaukee, Wis., and from Toledo to Detroit, Mich. Through these branches and through connecting lines all important points in Ohio, Indiana, Illinois, Michigan and Wisconsin will soon be reached.

The New York-Chicago line is 950 miles in length, and is constructed in the most substantial manner. The poles are of cedar and chestnut, 35 feet and upwards in length, and average about 45 in number per mile; making the total number of poles 42,750.

To determine the feasibility of transmitting speech over the heretofore unapproached distance of nearly 1,000 miles, a special experimental circuit, consisting of two No. 8 hard-drawn copper wires has been constructed. This wire weighs 435 pounds to the mile, and the circuit contains 826,500 pounds of copper. A circuit of the size generally used for telephone service would weigh less than 200,000 pounds.

The use of cables, which are so detrimental to long-distance telephone tranmission, has been avoided to the utmost possible extent, and they are used in the line only at the terminals and at the river crossings in the immediate vicinity of New York. Prior to the construction of this line, the limit of successful transmission did not exceed 500 miles.

At the conclusion of the telephonic exhibition the guests were handsomely entertained at luncheon by the officers of the Long Distance Co., and each was presented with a souvenir, consisting of a helix of the No. 8 copper wire, of which the line is constructed, with miniature receivers attached to the ends. The line is now open for regular business.

TWISTING MAGNETISM.

BY

Townsend Wolcott.

Mr. S. W. Balch's note on "Twisting Magnetism" seems to have aroused considerable interest, but in the humble opinion of the writer both the gentlemen who have offered explanations of the non-production of current in the apparatus shown in Fig. 3 are in error. Mr. D. C. Reusch's explanation, if I understand it, explains too much. It would prove that the Fig. 1 apparatus would not give a current, which is somewhat startling in view of the fact that this figure represents one of Faraday's early experiments, in which he obtained a current. This apparatus is, therefore, one of the oldest known forms of generator. Mr. Reusch's quotation from Thompson's "Dynamo-Electric Machinery" does not apply to this kind of generator. I have never seen the whole story of magneto-electric induction summed up in a single sentence, and I doubt the possibility of doing it, at least in the English language. Mr. Steinmetz's explanation is certainly very ingenious, and at first sight very plausible, but the statement that "the magnetic field of a magnet does not revolve when the magnet is revolved, but remains stationary," I cannot endorse. This idea is not a deduction from the fundamental principles of magnetism, and appears to be an independent assumption made for the express purpose of explaining the experiment under discussion, or others of like nature. It will presently appear, however, that it is unnecessary, even for this purpose, besides which it leads us into numerous difficulties if followed out to its legitimate results.

Let the galvanometer in Fig. 1 be replaced by an electrometer and the ends of the wire, instead of being placed in actual contact with the revolving magnet, be brought near it without touching. Then if the field revolve, the electrometer should be deflected (provided it be sufficiently sensitive), otherwise there should be no deflection. But without this direct experiment which might be troublesome in practice, let us investigate other forms of magnets. For the sake of simplicity solely, the magnet in Fig. 1 has been tacitly assumed to be truly cylindrical, symmetrically magnetized, and revolved about its geometric axis. Under these conditions there is no logical difficulty in assuming the field stationary, but neither is there any logical warrant for such an assumption. If, however, the magnet have a cross-section other than circular, for instance square, there would be a current generated just the same (except that it would be slightly pulsatory instead of absolutely constant) but the field could scarcely be said to be stationary in any proper sense of the word. If it still be held that the field does not revolve as a whole, it must at least have internal motions (re-arrangements of lines) in order that the field may bear a constant relation to the iron (or steel) of the magnet. This is certainly a very artificial assumption, made to bolster up the first assumption, a process of reasoning which is never necessary to a true theory.

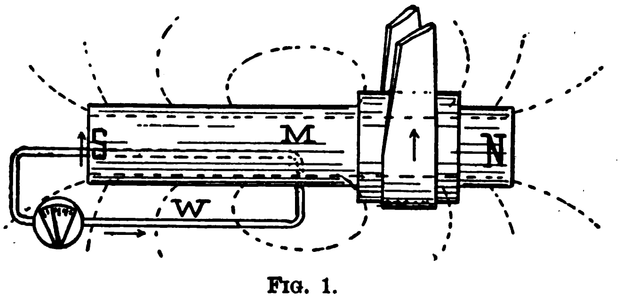


Fig. 1.

Next, suppose the straight bar magnet of Fig. 1 to be replaced by a horseshoe magnet, which rotates upon the axis of *one limb*, the other limb of course traveling in a circular orbit. This apparatus will still furnish current, but I fail to see how, by even the utmost stretching of the meaning of words, the field can be said to be stationary. Further, let the small circle in the subjoined diagram represent the end view of a bar magnet traveling with its axis parallel to itself in the orbit represented by the large circle. Now certainly the field of this magnet follows it around the orbit, whether it be supposed to follow the coincident rotation of the magnet upon its own axis or not.

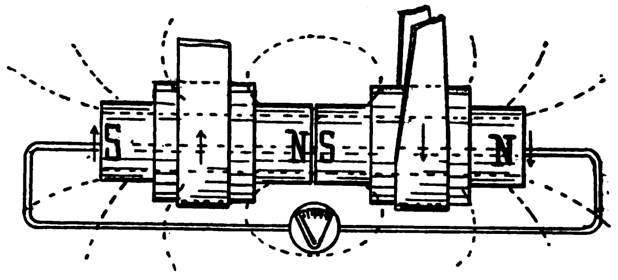

Fig. 3.

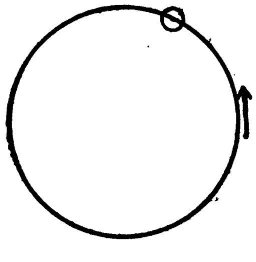
Next, suppose the magnet reduced to a filament, and then the whole circle packed full of such filaments, and we have the magnet of Fig. 1 with its field revolving *with* it. I had supposed that every one, from Faraday down, had considered the field of a revolving magnet to revolve with it, and had the contrary statement been made by a person whose opinion is of less weight than Mr. Steinmetz's, I should not have considered it necessary to contradict it so elaborately.

The philosophy of the Fig. 3 experiment is to my mind as follows: Mr. Balch's assumption that a portion of the field revolves with each portion of the magnet is correct, except that he does not mentally divide his field in the way in which nature divides it. He supposes the field of the whole magnet to be cut squarely in two by the plane which divides the magnet, whereas the field should be resolved into two component fields according to the parallelogram of forces, which is the only way that forces can be separated. If this be done we have two separate fields, the same in fact which we have if the halves of the magnet are separated until out of each other's influence.



Let us suppose them so separated, (the conductor being sufficiently long for the purpose) and revolved in opposite directions; no one would expect to get a current. When they are brought end to end the fields are interlocked, and so far as a magnetic needle is concerned they form a resultant, but so far as magneto-electric induction is concerned they still act separately.

The whole Fig. 3 experiment is, in fact, only a particular case of the well-known and very fundamental property of magnets, namely, that if we cut a magnet in two, we have not too halves of a magnet each with one pole, but two half-sized complete magnets, each with two poles.

In 1886 I read before the New York Electrical Society a paper in which this same philosophy was applied to the theory of dynamos, but it does not seem to have taken root.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 203 *Broadway, New York City.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can 'entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XIV. NEW YORK, OCTOBER 26, 1892. NO. 284.

If it were put to a test to-day in the city of Cleveland, there would be twenty to one in favor of the electric or cable system.—Mayor Rose, of Cleveland.

OPENING OF THE NEW YORK—CHICAGO TELEPHONE LINK.

THE 18th of October, 1892, will always be a red-letter day in the history of the telephone business. On that day there were gathered together in the Telephone Building on Cortlandt St., New York, a large company of representatives of the Metropolitan press, and, at the same time, there was assembled in the office of the Long-Distance Company, in Chicago, a similar gathering of representatives of the press that city. Connecting these groups, a thousand miles apart, were two very heavy copper wires, equipped at each end with a Long-Distance telephone outfit. As a special guest at the New York end was Mayor Grant, and filling the same role in Chicago was Mayor Washburn. Another guest in New York was Prof. Alexander Graham Bell, the inventor of the telephone.

The hour for the formal ceremony had come, and Mayor Grant, in New York, speaking in an ordinary tone, accosted the Mayor of Chicago a thousand miles away. Mayor Washburn's reply came promptly and distinctly. It was ingeniously arranged that their Honors should not have their chat entirely to themselves. At both ends some forty hand telephones were connected in, so that other guests could listen and hear the conversation. In effect, therefore, it was the same as though the two speakers were in the same room, with the two companies of journalists gathered about them, listening to their conversation. And so the two great cities were brought within easy speaking distance of one another; their union was made complete and perfect, and it was duly witnessed. It is safe to say that they will never again be satisfied to live asunder.

An interesting incident was the conversation between Professor Bell in New York and Mr. William H. Hubbard in Chicago. Mr. Hubbard assisted Professor Bell at the Centennial, in Philadelphia, in 1876, when the telephone was first publicly exhibited, and the two have not conversed by wire since that time.

Few will realize what it means to have accomplished this. Only those who have watched the work, who have known the obstacles that have been overcome, the objections that have been met, the electrical and engineering problems that have been solved and the false theories that have been exploded, only those who realize how persistent the effort has been, how wise the generalship necessary to direct all the various forces and bring about a successful result—only these do, or can, comprehend the proportions of this great enterprise which has had so successful an issue.

Be it remembered that this Chicago line, which is double the length of the longest telephone circuit hitherto operated in the world, is but a part of a great system, a link which connects the well-known Long Distance plant, which practically covers New England, New York, Pennsylvania, Maryland and the District of Columbia, with the great cities of the West. It is not New York alone that can now converse with Chicago. Boston, Philadelphia, Baltimore and Washington share the privilege. So, too, do lesser cities. Worcester and Springfield and Hartford and New Haven, Albany and Troy and Syracuse and Rochester, Buffalo and Erie and Pittsburgh and Cleveland; these, and many other cities, because of work previously done, and all planned with a great system in mind, have as much interest in the completion of this thousand-mile link as New York itself.

It is interesting to trace the growth of the telephone business since its small beginning in 1876. It was while the nation was celebrating the completion of its hundredth year that the "still small voice" of the telephone was first heard. Then it was little more than a scientific toy. And yet, in all its essentials, it was the same then that it is to-day. Improvements in apparatus have been made, many and notable. But the essential thing is the growth of the business, the creation of a great commercial enterprise, which has made this scientific toy the servant of man, a well-nigh indispensable agency in the daily life of the civilized world. A great advance was made when, by what is known as the "exchange system," persons living within the limits of a municipality were enabled to communicate with one another. Yet this was but a step. Hardly had it been taken when the need of communication by speech between neighboring municipalities became apparent. This was brought about by combination of effort in each case. Then it was seen that some more comprehensive plan, one that would give uniformity in appliances, in methods and in organization, one that would cover larger areas and bring more remote communities into intercommunication, was needed. The end in view, even yet remote, perhaps, but still in view, was a great national "exchange," one that would enable a business man, sitting in his own private office in Chicago, Milwaukee or Detroit to converse as easily and promptly with friends in Boston or New York or Washington as with those who reside within a mile of his place of business. To accomplish this, the American

Telephone and Telegraph Company was organized, and it has kept steadily at work, always with this ultimate object in view.

THE ELECTRIC RAILWAY CONVENTION AT CLEVELAND.

A LARGE portion of our space this week is devoted to the report of the proceedings of the American Street Railway Association at Cleveland last week. As will be seen, the Convention is largely, one might almost say, overwhelmingly, electrical in its makeup and tendencies, and its proceedings are as much electrical as those of the National Electric Light Association. That this is so, at a very early stage in the art, is matter for hearty congratulation, and is a grand incentive to grapple with the problems and tasks that still await, in even more extensive departments of traction.

With perhaps one or two exceptions the reports submitted by the various committees at the meeting of the American Street Railway Association, were productions of genuine merit, the value of which will be fully appreciated on close scrutiny. The subjects covered by the committee embraced a wide scope of street railway work, and ought to have satisfied even those members who are still operating horse roads, and who have recently been heard to complain that the proceedings of the Association were of little interest to them. In reading the report on Standards for Electric Street Railways, it becomes evident that the art is still in such a pronounced stage of transition, that exact standards at this early date are hardly determinable. The committee has done well, however, to bring together such information as will enable the members to form an opinion based upon the general practice of the day, and the standards suggested in the report may well be taken as a guide in pointing to probable future practice. The proposed standard for rating the capacity of street railway motors, certainly has the merit of simplicity, though it fails to take into consideration the efficiency of the motor, being based solely upon the torque at a given speed. We agree, with the report, that, desirable as it would be to know the efficiency of the motor, it would be difficult to involve that factor in a rating that shall be frequently and properly used. But on the other hand, we do not believe that it would involve much additional trouble to take current and voltage readings during the operation of a car under test, and to thus obtain at least an approximate idea of the efficiency.

The committee report on Experiments on the Expansion of Continuous Rails is noteworthy in that the results therein recorded appear to upset all our preconceived notions on track construction, more particularly that one which, in the past, dictated the necessity of allowing for expansion and contraction of rails with temperature variations. The report is largely based on a record of the work of Mr. Philip Noonan, and, this, if correctly recorded, appears to leave little room for argument as to the feasibility of a jointless rail, a proposition which we are free to say, has not heretofore met with the approval of railroad men of experience. If the method should continue successful, there would appear to be nothing in the way of the rail being made continuous by electric welding. The latter will greatly simplify and reduce the cost of construction, as Mr. Noonan's method, though apparently giving excellent results, must of necessity involve considerable, though we are by no means prepared to say, unless, expense.

The report on Economy of Machine Shops for Electric Street Railways presents a very curious state of facts. We are first struck with the large percentage of roads operating electric cars, which have practically no facilities for making even ordinary repairs, while, on the other hand, it is shown pretty conclusively that the maintaining of repair or machine shops in connection with electric roads contributes largely to economy in operation. While strongly recommending the establishment of such repair shops to take care of ordinary depreciation of railway stock and equipment, the report goes even further and urges the economy of manufacturing, by the railway companies themselves, of supply parts used by them. Based not only upon the results obtained by the electric roads who have tried it, but also on the experience of the older steam roads, it is fair to assume that this recommendation will be carried out by not a few roads in the future. Aside from the patented devices, there are numerous electric railway supplies which can be renovated economically by the companies themselves, and it would be strange indeed if they did not avail themselves of this opportunity of reducing their expenses.

It seems to us a great pity that the movement to organize a supply men's auxiliary association was not successful. The fears expressed as to a control of it by the few strong at the expense of the many weak, are unworthy of the energetic men engaged in an industry so progressive and so diversified. If only to look after the exhibits, such a body is needed. The display at Cleveland was very fine, but the vast majority of those who came to see it were "hayseeds" and women, of whom not one in a million buys street railway or mechanical apparatus. What is wanted is the careful and thorough preliminary canvass of the community, so that when the Association goes to a city with its exhibit, the Supply Secretary has interested by direct appeal every merchant, manufacturer, capitalist, inventor and machinist in the community. That is the kind of *outside* public to be reached, and the only kind that the active operating street railway men themselves want to meet on such an occasion.

Conspicuous Ability.

IT is but giving just credit where it is obviously due to say that the successful establishment of telephone service between New York and Chicago is largely due to Mr. Edward J. Hall, vice-president and general manager of the American Telephone and Telegraph Company. Mr. Hall has had immediate charge of the affairs of the company from the beginning. His distinguished ability as an executive officer, and his untiring efforts, have been a striking factor in the progress and completion of this great work.

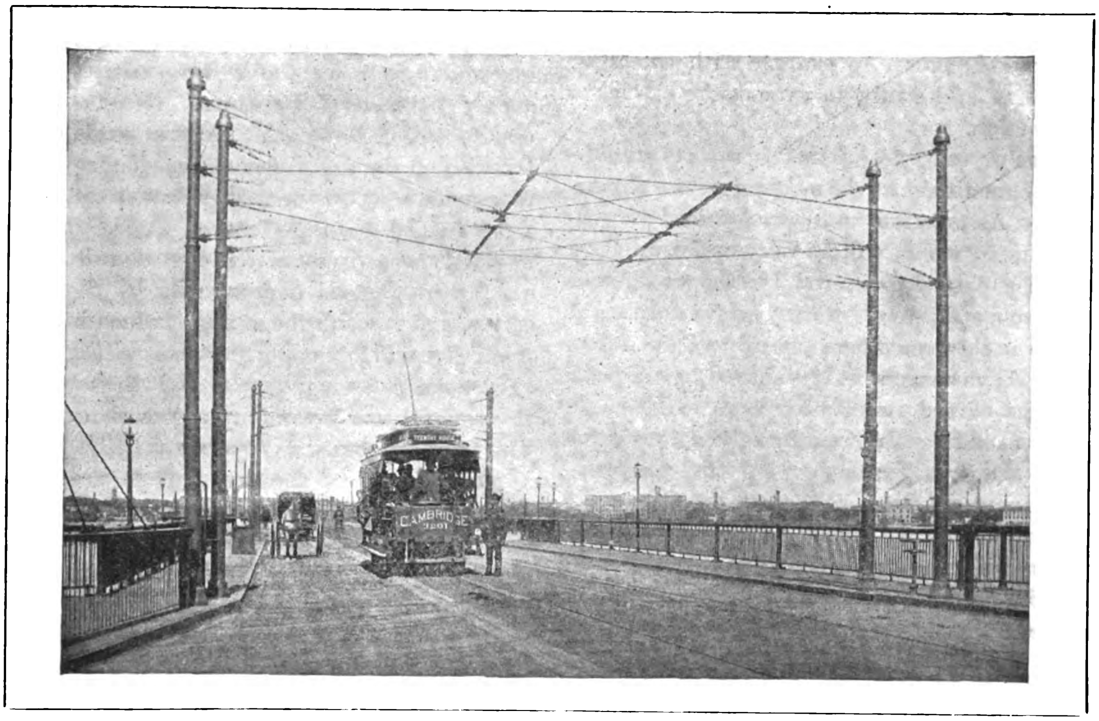
The New Westinghouse Lamp.

THE determination of the Westinghouse Company to supply its customers with incandescent lamps, alleged to be independent of the recently sustained Edison patent, has resulted in the construction of a lamp with a removable stopper as mentioned by us two weeks ago. The adoption of a conical joint in place of the flat joint, early applied in the art, is no doubt the secret of its success.

ELECTRIC RAILWAY DEPARTMENT.

OVERHEAD LINE CONSTRUCTION ON HARVARD BRIDGE.

ALTHOUGH the tracks for the electric cars have been laid on the new Harvard Bridge over the Charles River, at Boston, for nearly a year, the electric equipment has been delayed by litigation until very recently. Once started, however, the work has been rapidly pushed to completion and presents to-day an appearance that is probably unsurpassed by any piece of overhead construction in the world.



OVERHEAD LINE CONSTRUCTION ON HARVARD BRIDGE, BOSTON.

A point of especial interest is the method adopted to obtain a practically continuous wire over the draw. It is strong and thoroughly efficient, and, at the same time, neat and unobtrusive in appearance and very light in weight. As will be seen from the accompanying illustration the arrangement is such that the trolley wheel travels from the end of a pointed terminal onto a flat, pan-shaped plate, the former being suspended several inches directly below the latter. As the wheel runs under the pointed terminal it presses it up until the flanges come in contact with the flat plate, thus making a mechanical connection and forming a continuous line. The wire is thus ready for the car to pass the instant the draw is closed.

The character of this piece of work is highly creditable to the West End Street Railway Company, of Boston, and it is hoped that the result will inspire other companies throughout the country to equal efforts in the same direction.

AN IMPORTANT ELECTRIC RAILWAY PROJECT IN NEW JERSEY.

ARTICLES of incorporation have been filed for a new street railway to begin at Morris avenue, Elizabeth, and run through to Orchard street, to Westfield avenue, to Grove street, to West Grand street, to Jersey avenue, thence through Third avenue in Linden township to Walnut street, in Roselle, and be continued through Cranford township to the Central railroad depot at Westfield. The road will be operated by electricity. The capital stock is $100,000. It will be known as the Elizabeth and Plainfield Street Railway Company. The incorporators are Supt. W. H. Peddie, of the Central Railroad; J. B. McGiffert, superintendent Suburban Electric Light Company; J. H. Vail, chief engineer Edison Electric Light Company; H. P. Baldwin, general passenger agent Central Railroad; James Garwood, of the Garwood Land Improvement Company; Foster M. Voorhees, Luther M. Whitaker, of Westfield; Dwight F. Barrett, of Cranford. The road will be seven miles long and in time will be extended to Plainfield. Applications are to be made at once to the authorities of the various municipalities which the proposed road is to traverse.

THE SHORT GEARLESS MOTOR.

IT seems somewhat strange, even in this day of rapid progress, that the gearless motor, so familiar to electric railway men, was scarcely thought of a year and a half ago. The first example of this type was a four-pole machine flexibly mounted upon the car axle and having the magnets presented to the sides of the armature. It was rather too heavy in its construction, and 36-inch wheels upon the truck were necessary. This was afterward modified by mounting the armature on a hollow shaft connected with the axle by means of a flexible driving device. The next

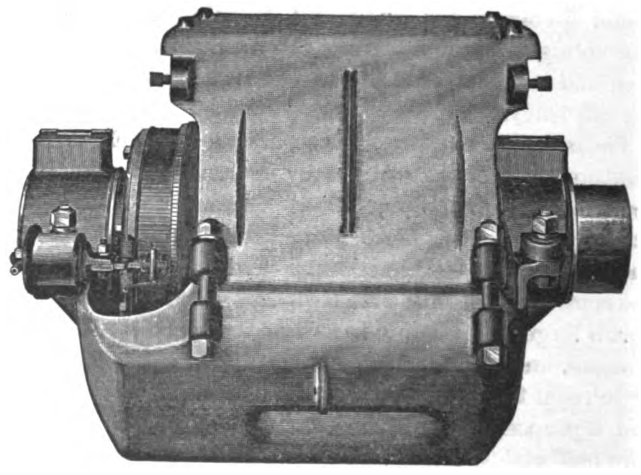


FIG. 1.—THE NEW SHORT GEARLESS MOTOR.

improvement consisted in presenting the pole-pieces to the face of the armature, instead of the sides, and also in modifying its form, widening the face and diminishing the diameter so that 33-inch wheels could be used.

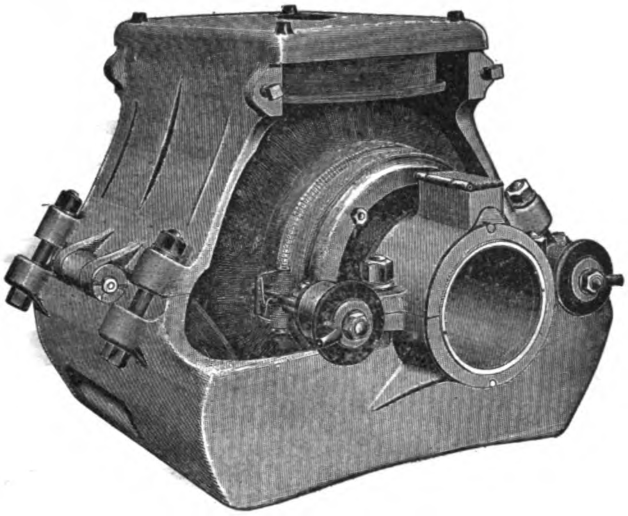

FIG. 2.—THE NEW SHORT GEARLESS MOTOR.

Not content with their success, the Short Electric Railway Company have now perfected another type of gearless motor, embodying important improvements, two views of which are shown in the accompanying illustrations. This motor, which was shown at the Street Railway Convention in Cleveland, is a six-pole machine, weighing, complete, 2,300 pounds. The frame is cast from steel in two sections; the upper half is supported by the truck; the lower half is hinged to the upper, and may be swung down when a car is over a pit, so that inspection is rendered easy. The lower half of the frame is cast without any opening up to the level of the centre of the axle, so that the motor may run through water and slush without any possibility of their penetrating inside the frame. Practically, therefore, the machine may be considered a waterproof motor. The armature is twenty-one inches in diameter, and, as in previous types, is mounted on a six-inch hollow shaft through which passes a four-inch axle. To the end of the armature shaft is a flexible driving device for connection with the car axle.

The diameter of the armature is sufficiently decreased in the new type, so that 30-inch wheels may be used with a clearance of three inches between the bottom of the motor frame and the track. The six poles are presented to the face of the armature. The latter is built with 92 bobbins, with 16 turns of wire on each, which are connected to 184 commutator bars. The armature is designed to run at 120 revolutions per minute when developing 20 h. p. Two of these motors will exert a horizontal effort of 1,500 lbs. in starting a car with eighty amperes, and with from 18 to 20 amperes will propel an ordinary car at a speed of about 20 miles an hour.

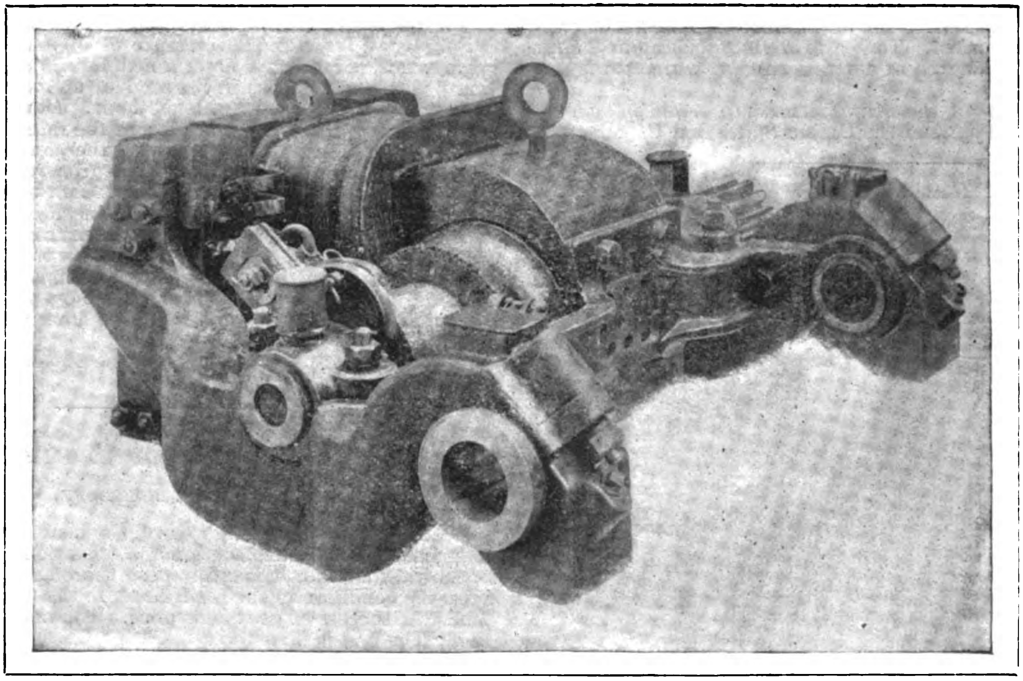
THE "S. R. F." 30 RAILWAY MOTOR.

THE many advantages of the single-reduction motor for electric railway service have, during the past year, been so emphatically proven that the General Electric Company has re-designed its old double-reduction F. 30 motor, making it a single-reduction machine and designating it as the "S. R. F. 30 Railway Motor." In compliance with the demand, already apparent, for the conversion of F. 30 motors, the company is now rebuilding, for many of its customers, a considerable number of these machines.

In effecting the change, the side arms, nose plate, intermediate shaft pinion and gear of the old F. 30 motor have been discarded and replaced by newly designed side arms which support the motor proper. As will be seen from the illustration, they occupy a position exactly the reverse of that in the F. 30. The nose plate becomes a support to the pole-pieces, and the pinion and gear are similar to those used on the General Electric Company's W. P. railway motor.

By doubling the turns or convolutions in the armature winding, and leaving the field spools unchanged, two very important improvements have been secured—the armature speed is reduced one-half, and the strength of the torque of the motor doubled. An improvement has been effected in the arrangement of the armature bearings, facilitating lubrication. The axle and armature bearings are now similar and the same kind of grease can be used on both.

The efficiency of the new S. R. F. 30, when compared with that of the F. 30, shows a decided increase in favor of the new type, although its speed under similar condition of strength of fields is slightly less. The amount of heat developed after a run under full load is also considerably less than in the F. 30. The satisfactory results of the trial tests of S. the R. F. motor tend to show that the transformation of the F. 30 from a double-reduction to a single reduction motor will be satisfactory wherever effected.

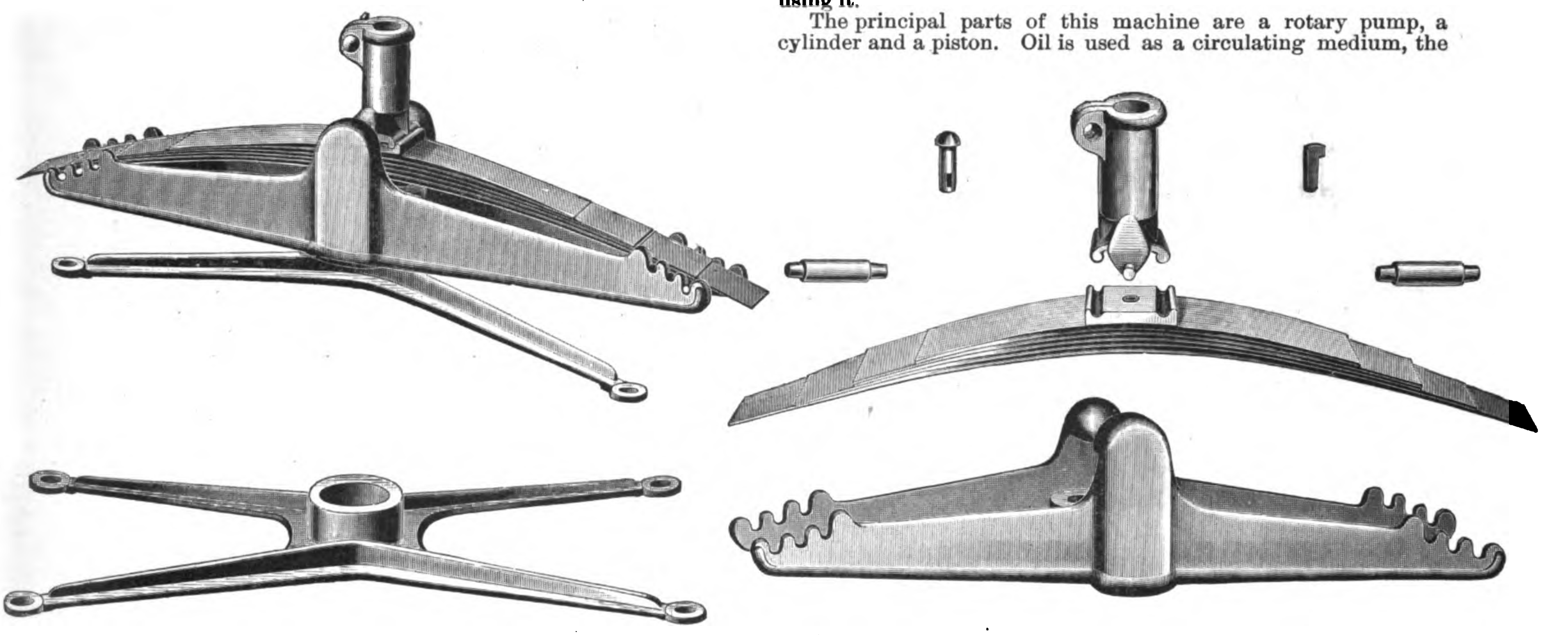


THE "S. R. F." 30 RAILWAY MOTOR.

THE LOWELL ELECTRIC RAILWAY.—With reference to the article in the last issue of THE ELECTRICAL ENGINEER on the Lowell and Suburban Street Railway Co., it should be stated that the whole system—plant, specifications for engines, piping, boilers, etc. —were under the supervision and direction of Col. L. R. Greene, of Boston.

THE PHILADELPHIA TROLLEY.

THE Philadelphia trolley, manufactured by the Technic Electrical Works, of Philadelphia, and shown in the accompanying illustrations, was designed with a view to embodying substantial mechanism with lightness and durability of parts. As will be seen it is composed of but nine pieces, among which there is not a nut, bolt, screw or washer. There are no chains nor coil springs, no wrench is needed for assembling or dismantling and no lubrication is required. The parts are interlocking and interchangeable and the degree of tension can be varied through a wide range.

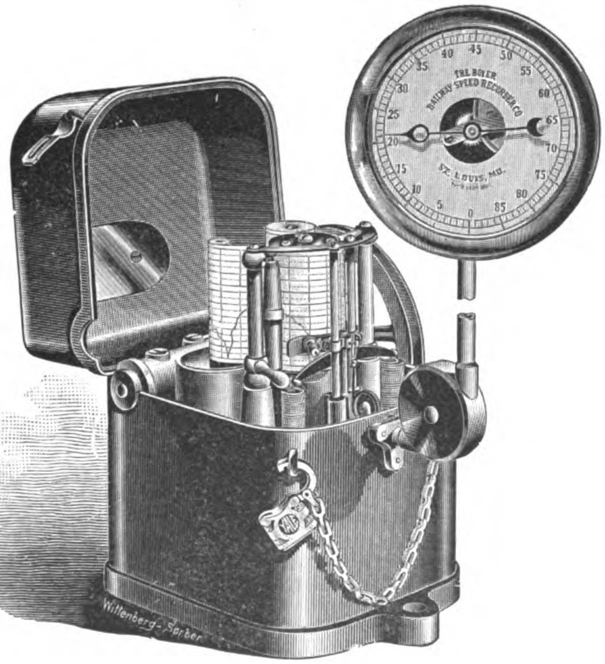


THE PHILADELPHIA TROLLEY.

It is the intention of the manufacturers to establish agencies for this trolley in all parts of the United States and Canada.

THE BOYER RAILWAY SPEED RECORDER.

THIS instrument, shown in the accompanying illustration, is designed to meet the demand of railway officials for an accurate speed recorder and indicator, that can readily be applied to street railway cars, and not only record on paper, but indicate on a dial similar to steam gauge, the speed in miles per hour. When the recorder is attached to a locomotive, the indicator is placed in the cab so that the engineer can see at a glance the actual speed he is running at, as easily as he can see by the steam gauge how much steam he is carrying. When attached to a car, the indicator is placed anywhere to suit the convenience of the parties using it.



THE BOYER RAILWAY SPEED RECORDER CO.
ST. LOUIS, MO.
Wittenberg-Gerber

BOYER RAILWAY SPEED RECORDER.

The principal parts of this machine are a rotary pump, a cylinder and a piston. Oil is used as a circulating medium, the pump chambers and cylinder being entirely filled. While the machine is at rest, the piston to which the gauge wire and pencil are attached, is retained in its lowest position by two coil springs, but when given motion the pump produces a pressure of oil beneath the piston, causing it to rise to a point where an equilibrium is established between the pressure of oil and the tension of the spring, this point being determined by the speed at which the pump is moved; each thirty-second of an inch rise of the piston indicating a speed of one mile per hour. Moving around a drum in the upper part of the machine, at the rate of one-half inch to the mile, is a ribbon of paper, having thereon horizontal and perpendicular lines, each horizontal line from the base or zero line representing five miles per hour, and each perpendicular line, a mile post along the road. A line is traced on this paper with a metallic pencil, showing, by its distance from the base line, the exact speed at which the train passes any point on the road, the number and location of stops, the distance traveled, and the location and speed of any backward movement that may have been made. It records and indicates from 0 up to 90 miles per hour.

The device is manufactured by the Boyer Railway Speed Recorder Company, St. Louis, Mo.

A MODEL ELECTRIC STREET RAILWAY ROADBED AND UNDERGROUND WIRING.[1]

BY G. W. BAUMHOFF.

THIS subject, embracing one of the most important questions connected with the construction and operation of a street railway, is one that should have the most thorough consideration, for, upon the condition of the roadbed more than any other item, depends the success of your enterprise. The motto should therefore be: "The best is none too good."

Your committee has decided, in submitting this report, to dwell chiefly on the merits of various types of rail known as the girder system, and in order to place the same before you in an intelligent manner will proceed with an itemized report in the order in which the construction is proceeded with.

First.—SURVEY. Having decided on the style and weight of rail to be used, and the chairs, fastenings and joints, the first step, in order, is to properly survey the route, if a new road; to estimate the quantity of cut and fill where grading is necessary, and the most advantageous manner in which to provide for the same; and to locate all curves, switches and turnouts. In doing so, care should be exercised to provide for all curves the longest possible radius at points entering and leaving the same, and to provide for the proper elevation of the outer rail of all curves, which should be elevated from one inch to two inches higher than the inner rail, where the condition of the street will permit; particularly in any curve of short radius, and more especially when such curve is located on a down grade.

---

[1] Abstract of a report presented at the meeting of the American Street Railway Association, Cleveland, Ohio, Oct. 19-21.

The switches, or cross-overs, should be located at such points along the route as will best provide for the following contingencies: Bunching cars for large gatherings, and to insure the constant operation of cars during fires, parades and all other blockades, when from any cause, the terminus of the road cannot be reached. They should never be placed with the switch point against the traffic; and preferably, on up grades, thus enabling cars to cross to the opposite track by gravity.

Second.—EXCAVATION. The depth of excavation must be determined by the thickness of the cross-tie, height of rail, and height of chair, if chairs are used, plus the space allowed for tamping. The condition of the soil must govern the latter exclusively, but in the reconstruction of the roadbed, where the operation of of cars will permit, and in all new work, unless the soil is of a sandy character, the following plan will not only provide a suitable sub-drainage, but insure permanency: Remove all earth to a depth of 8 inches below the bottom of the cross-tie the full width of the trench; then roll thoroughly with a heavy four-horse ro steam roller; then spread with a layer of cinders, crushed rock, gravel or furnace slag, from 6 to 8 inches in thickness, and again roll until the same is well bedded and leveled. A trench 7 feet in width, with a layer of 8 inches, will require for one mile in length 24,640 cubic feet of material, estimated at 3½ cents = $862.40, and will require the removal of 912 yards of earth, estimated at 25 cents = $228; add for rolling, $50. Total, $1,140 per mile of singe track.

Third.—CROSS-TIES. Under this heading we have the metallic tie and various kinds of wood. The committee's remarks will be confined to the latter exclusively. The size should never be less than 5 x 8 inches for rail 56 pounds and over, and if laid as closely as good tamping will permit—say 27 inches from centres—will materially strengthen the roadbed and assist in holding up the joints. For joints where wide joint chairs are adopted, one tie of sufficient width is preferable, as it is impossible to insure good tamping where two small ties are used at the joints. If the above size is decreased, it should be in thickness rather than in width, to insure the tie from splitting, which is often caused by the spike being driven too close to the edge. The committee recommend the white-oak tie.

Fourth.—RAIL. In the selection of the rail depends largely the success of perfect construction; and a road, whether built for speculative purposes or as a permanent investment by the projectors, should not be slighted in this respect. The requirements of a rail for electric traction are strength, joint connections, durability. In some localities there are municipal requirements specifying what the head of the rail shall be. For strength we rely chiefly on the weight of the rail, and the thickness and depth of the web. For joint connections, that rail which affords the best method of keeping both ends of the rail in perfect alignment is the best, and as the girder rail possesses peculiar advantages in this respect, its almost universal adoption is due to that fact. For durability, we depend on the height of the head of the rail at the gauge line over the lower flange, and the quality of the metal.

The report then gives the result obtained on rails by Dr. C. B. Dudley, chemist of the Pennsylvania Railroad and the specification for steel rails.

The subject relative to the quantity of the various elements entering into the manufacture of steel, which shall produce the rail calculated to give the most wear, and yet avoid brittleness, is one in which there is a great divergence of opinion. The rail over which electric motors are operated through thoroughfares in various cities throughout the country is certainly subject to as much wear as, if not more than, that of many of the trunk lines; and as we have patterned closely after their method of construction, we may perhaps profit by following their example in other details.

Of the various forms of the head, the centre-bearing rail is the most desirable, because, with a lower tram on each side, the head is kept free from dirt, and consequently offers less resistance to the car wheels.

Next to the centre-bearing form of head, the side-bearing head is by far the most desirable, from the operator's standpoint; for the only other form made, of the girder type, is that with a groove, instead of a lower flange. The latter form of head is suitable only for curves and cross-overs, when rolled with a wide groove, and should never be adopted for straight track, owing to the tendency of the groove to hold dirt, snow and ice.

In the selection of a girder rail of any form of head, and more particularly the style known as side bearing, it would be well to remember that the rail having the widest base offers the greatest resistance to turn over; and care should therefore be exercised in the selection of the rail, to secure the widest possible foot, and your committee would urgently advise enlarging the rolls at the base of the rail, in order that the same shall at least equal in width the combined width of the tread and lower flange.

Fifth.—CHAIRS. If chairs are required, care should be exercised in selecting such as will insure the greatest possible bearing on the tie, and such only as will not spring under heavy loads. A chair with a narrow base is apt to cut into the cross-tie, and in time work loose or cause the rail to cant. All intermediate chairs should be provided with a brace extending well up under the outer head of rail, which is the best safeguard against the rail turning or canting.

Sixth.—JOINT SUPPORTS. Your committee would very urgently recommend the adoption only of such joint-supports as are of sufficient length to cover at least two ties, but consider such as secure a bearing on three ties preferable. The holes in the web of the rail should be not less than one inch in diameter, to admit the use of a bolt having a large size nut, which should be tightly secured by the use of a hammer and wrench. A six-hole fish-plate of sufficient height to reach from the foot of the rail to the bottom of the head, 26 inches or over in length, securely fastened with large size bolts, is considered by many who have used the same to be superior to all other joint fastenings.

We must bear in mind that cars, as now operated by electricity, are not only heavier than horse cars, but are operated at a much higher rate of speed, and require the most thorough construction. The slightest spring, or looseness, will gradually result in a low joint, which if not soon attended to, will ruin the end of the rail beyond repair. It would, therefore, be well to relieve the fish-plate of much of this strain, by providing a support for the bottom of the rail extending over two or more cross-ties.

There exists among railway managers a difference of opinion as to the choice between a supported or suspended joint. Your committee, however, earnestly recommends the supported joint, with a support for the bottom of the rail extending to the adjacent ties, and does not deem it advisable to adopt the suspended joint construction, unless the joint support has a firm bearing on the adjacent ties. There are a number of such joint chairs of various manufacture now in use, which your committee are reliably informed are giving entire satisfaction.

There is also a diversity of opinion as to the location of rail-joints with respect to each other, and on this subject we do not hesitate to take a firm stand in support of the joints being laid directly opposite each other, when constructed for electric traction, as the tendency where laid with broken joints is to cause the car to sway sideways, particularly at a high rate of speed, if the joints are not kept extremely perfect. The former plan renders it also more economical to repair joints, especially in paved streets.

Seventh.—PAVING. Of the various kinds of paving now in use, the following are chiefly adopted, and about in the order in which they are named: Granite, telford, asphaltum, wood and brick. The former being by far the most durable, most cheaply maintained, and less expensive to remove and replace, for the necessary track repairs, justifies the adoption of the same over that of asphaltum, wood or brick, and warrants the additional first cost, which accounts for its almost general adoption by street railway companies where paving is required, and by municipal authorities on streets where railway tracks exist, or are contemplated. In some localities asphaltum paving is adopted on streets where railway tracks are laid; but owing to the tendency of vehicular traffic to wear ruts alongside of the rail and the spring of the rail to loosen the paving material, together with the increased cost of repairing the same, it is not as favorably considered, for track paving, as some of the other systems.

To overcome the first-named objection in some locatities where this paving is adopted, a double row of granite blocks is laid, adjoining the rail, which also provides for the vibration of the rail and renders it more accessible to get at the foundation of the roadbed for necessary repairs.

Telford paving is not suitable for thoroughfares subjected to heavy vehicular traffic, and should only be adopted for street railway tracks on suburban divisions, where, owing to its cheapness, it is quite extensively adopted.

Brick in any form, made of clay or other material, has thus far not stood the test of vehicular traffic to warrant its adoption in any climate, either by railway companies or municipalities, and should, therefore, be given a most thorough trial before it is extensively used.

With girder rail construction, it is advisable to fill in the web of the rail with moist clay just before paving, in order to prevent the paving blocks from working loose, caused by the sand surrounding the same filling up the space, thus leaving the blocks unprotected, and tending to cause the row of blocks adjacent to the track to settle unevenly. In some localities an iron frame is constructed at each joint for the purpose of providing for repairs to the same, without disturbing the paving, but with the latest girder rail joint construction, ties well tamped and bolts securely fastened, the necessity for such construction does not exist.

Eighth.—UNDERGROUND WIRING. A large-size insulated copper wire is generally adopted to form the connection between the generators and such points along the track as it is deemed advisable to reach. The return circuit may be completed, either by connecting said wire to the rail, or to a supplementary wire extending the entire distance of the track. The latter is in all cases recommended, and should invariably be soft copper wire, not smaller in size than No. 0. In either event, however, all rail joints should be bonded with a soft copper wire not less in size than No. 6, and if the supplementary wire is laid, a connection thereto should be made to at least every fifth rail; and it will also be of great advantage as a safeguard against any possible break in the circuit, to connect both sides of the track with a No. 6 wire, and if a double track, to cross to the opposite track, and to the supplementary wire in said track, at least every thousand feet.

After a thorough trial of upwards of three years, during which time we have used both, the conclusion reached is, that copper being not only a better conductor than iron or steel, but less liable to corrode and break, is therefore the best wire to use for underground work. Galvanized soft steel or iron wire used for this purpose, has not proved durable, and we have found the same to be entirely eaten away by electrolysis where it had come in contact with the cross-tie, and in perfect condition elsewhere.

The only theory we can advance for this is, that a chemical action takes place between the gases of the earth, precipitated by the sap contained in the timber and salt water—the latter from the use of salt for the purpose of melting snow and ice—although such results have not been noticeable in the use of copper wire. In addition to cross-wiring, as above mentioned, as a precautionary matter, to insure a complete circuit, it will be found advantageous to the economical operation of an electrical railway, to excavate or bore in the earth, to a sufficient depth, to secure continual moisture, and whilst iron is usually adopted, owing to its cheapness, yet we believe the use of copper will, in time, prove the most economical metal to adopt for this purpose. Where such grounds are located, care should be taken to make the best possible connection to the supplementary wire and the track.

By a careful examination of the amperemeter at the power house, during dry weather, compared with that of rainy weather, it will be noticed that there is a marked decrease in the amount of current used, in favor of the latter; hence, it follows that the more connections to the rail and the opposite poles of the generator, with the most earth, the more economically is the system operated. It must also be remembered that the increased saving in current in wet weather, over that of dry weather, is not attributable to the increased moisture of the earth alone, but to the fact that the dust and dirt, which readily finds lodgment on the rail, is washed off, and many roads now in operation by electricity have found the use of a car equipped with a tank having one down-spout, about ⅝ inch in diameter, on each side, so arranged as to permit a stream to flow over the head of each rail, most advantageous. These down-spouts should be located as near the wheel as possible, in order to insure their being directly over the rail at all curves, as well as the straight track.

In conclusion, we have only to say, as to the construction of "A Model Electric Street Railway Roadbed and Underground Wiring," its successful accomplishment will involve the comparison and investigation of a wide range of personal experiences, coupled with the patient study of those engaged in the manufacture of rail and track supplies, who are constantly endeavoring at great expense to improve the material and method of construction.

STANDARDS FOR ELECTRIC STREET RAILWAYS.[1]

BY O. T. CROSBY.

THE committee as first determined consisted of the following members: O. T. Crosby, chairman; H. I. Bettis, who gave special attention to the matter of accounts; E. E. Higgins; Chas. W. Wason, named as mechanical member, and R. W. Rippetoe. The last-named gentleman resigned from the committee work shortly after its inception, and Mr. J. E. Rugg, of Pittsburgh, was appointed in his stead.

The thing on which definite recommendations were to be made to the Association was as follows:

1. Accounting methods. Concerning this the object of the committee will be to emphasize the three headings—transportation, maintenance and construction, under which expenditures are to be kept.

It was also concluded to present the car mile as the unit of operating expenses, especially in regard to the item of motive power. For the purpose of comparing motive power expenditures double-truck cars shall be distinguished from single-truck cars, while double truck cars shall be classed with trains of two cars.

Methods of Accounting.—While awaiting any further special treatment of the subject from Mr. Bettis, I beg to call special attention to the recommendation that a car mile be adopted as the unit of operation in regard to the item of motive power. The introduction of the double-truck cars into street railway service makes this unit, however, somewhat inaccurate unless the distinction between the various kinds of cars be carried along with the use of this term. We have thought that the distinction should rest rather as between double-truck cars and single-truck cars than between cars of different specified lengths. Furthermore, and especially relating to the question of motive power, we recommend that it will be reasonably safe to class two standard 16-foot cars with double-truck cars, experience having shown that the consumption of power in the two cases is nearly equal under given conditions as to track, grade, etc.

One of the chief difficulties heretofore standing in the way of determining accurately the cost of one mile of service has been the inaccuracy in the determination of the amount of power consumed for such unit service. The perfection of recording wattmeters that has taken place during the past year will go far towards remedying this difficulty. We do not feel it necessary to enlarge upon the importance of careful bookkeeping looking to the determination of these three headings. We assume that all intelligent railway men appreciate the importance of knowing what they are doing.

Standardizing of Specific Dimensions.—In regard to this heading I take pleasure in inserting herewith the report of Mr. C. W. Wason, sub-committee on this subject.

"In order to better determine the sizes of the several parts given me, as a member of the standardizing committee, I sent out circular letters to two hundred of the leading electric roads, requesting them to give their opinion as to the sizes of the several dimensions. "I would state right here that from the small number returned, namely, about thirty out of two hundred, that the street railroad companies do not realize the benefit to be derived from such a movement, else they would take the trouble of answering such questions of general information, thus enabling the committee to much better arrive at a satisfactory conclusion.

"In order to obtain the dimensions of the car journals, such as this committee may think best to recommend, I corresponded with the several truck manufacturers, who kindly gave me blue prints and drawings of their journal boxes. If the electrical manufacturers continue to increase the weight of their motors, these dimensions should be increased. The data I here present has been gathered from railroads, using possibly a lighter equipment than which is now being put upon the market. It is absolutely impossible to standardize an appropriate size, considering the change of weight, but the following seems to be the best in the opinion of those from whom I had answers to my inquiries:

Diameter of axle 3¼ inches.
Diameter of car axle journal 3 inches.
Diameter of axle wheel seat 3½ inches.
Length of car axle journal 8¼ inches.
Diameter of car wheel 33 inches.
Weight of car wheel 350 pounds.
Diameter of trolley wheel 4¼ inches.
Width of trolley wheel 1¼ inches.
Depth of groove in trolley wheel when new 1¼ inches.
Size of key way for axle gear ¼ inch by 6 inches.
Distance between hubs of wheels measured along the axle 48 inches.

It is essential that the groove and depth of trolley wheel be the same if the cars run over the same style of switches, as it is almost impossible to put up an overhead construction that will carry all sorts of trolley wheels. This remark may at first look a little absurd, but when one has had much experience with several different size trolley wheels he will at once appreciate the necessity of all being alike."

The diminsions above recommended as standard have been approved by the other members of the commitee to whom they have been submitted, except that Mr. Rugg prefers a 30-inch wheel instead of a 33 inch to be considered as standard. We have endeavored not to forget the principle referred to in the papers presented last year, namely: "That the standardization of parts should be so directed as not to interfere with the progress of invention." The dimensions of wheels and trolleys above given are intended to be applicable alike to single-truck and double-truck cars.

A large majority of the numerous persons addressed upon the subject, recommended No. 0 B. & S. gauge as the best size for standard trolley wire. It is further understood that such trolley wire shall be of hard drawn copper; its conductivity to be 98 per cent. of the standard in the usual tables used; its tensile strength close to 55,000 pounds per square inch.

Nomenclature.—The list of names suggested by the writer in the paper last year has been submitted to a number of railway officials, railway contractors and manufacturers of electrical goods. Some corrections of the list as presented last year have been recommended by various persons and are herewith incorporated. The name now recommended appears first, and after it in parenthesis is the one heretofore used for some articles.

Nomenclature of Electric Railway Terms.

Generator—(Generator, dynamo)—Machine in which the electric current is generated.

Motor—(Motor)—Machine in which the electric current is transformed into mechanical power.

Frame—(Frame) - Iron body of machine, including pole-pieces and standards or side arms, if any, but not including base plates and bearings.

Standards—(Standard bracket)—Supports of the bearings of generator.

Side Arms—(Side arms, check pieces, armature bracket)—Supports of bearings of railway motors.

Pole-Pieces—(Pole-pieces)—That part of the frame from whose surface lines of force may pass directly to the armature.

Field Coil—(Field coil, spool)—Coils of wires wound on frame in such a way that a current passing through these coils makes magnets of the frame and pole-pieces.

Brush Holder—Device for holding the brushes in contact with the commutator, including the insulation used in its support.

Rocker Arm—(Yoke, rocker arm)—Device for holding brush holders in position on commutator while attaching it directly or indirectly to the frame.

Fuse—(Fuse, fusible plug)—A metal device for opening circuit when the current becomes abnormally large, the soft metal being melted by a current of fixed quantity.

---

[1] Abstract of the Report of a Committee of the American Street Railway Association, submitted at the Cleveland meeting, Oct. 19-21.

Switch—A device for closing or opening a circuit at one or more points.

Rheostat—(Resistance box, rheostat)—Wire or other material suitably protected and conveniently arranged to be introduced in more or less proportion into a circuit.

Trolley—(Trolley contact bar)—A device used to transmit the electric current from the overhead wire to the cars, consisting usually of a

Trolley Wheel—A small metal wheel making rolling contact with the overhead wire.

Trolley Fork—Mechanically connecting trolley wheel to

Trolley Pole—Supporting the trolley fork and wheel and resting in a socket, which is part of the

Trolley Base Frame.

Trolley Wire—Wire from which the trolley wheel directly receives current.

Standard Trolley Switch—(Trolley frog, frog, overhead switch)—A device used to fasten or hold together the trolley wires at a point where the trolley wire branches, and to guide ordinarily automatically, the trolley wheel along the wire over the track taken by the car.

Trolley Switch—A switch designed for use at a point where two branch lines make equal convergent angles with the main line.

Right Hand Trolley Switch—A trolley switch designed for use at a point where a branch trolley wire leaves the main line to the right in the going direction.

Left Hand Trolley Switch—A trolley switch designed for use at a point where a branch trolley wire leaves the main line to the left in the going direction.

Three-way Trolley Switch—A trolley switch for use at a point where the line branches in three directions.

Drawbridge Crossover—A device permitting the easy passage of a trolley wheel from one to the other of two adjacent wires in a continuous direction.

Trolley Frog—(Trolley crossing, crossing frog, crossover)—A device placed at the crossing of two trolley wires, by which the trolley wheel running on one wire may cross the other, the device also holding the two trolley wires together.

Insulated Trolley Frog—(Insulated trolley crossing)—A device placed at the crossing of two trolley wires, by which the two wires are insulated from each other, and by which the trolley wheel running on one line may cross the other.

Hanger—(Line insulator, line suspension, trolley insulator)—A device for supporting and insulating the trolley wire.

Straight Line Hanger—The hanger used on a straight line and supported from a span wire, the strain on same being essentially vertical.

Single Curve Pull Off—(Single curve hanger)—The hanger supported by a lateral strain in one direction and, ordinarily, on single track curves, except at ends and the inside curve of double track.

Double Curve Pull Off—(Double curve hanger)—The hanger supported by a lateral strain in opposite directions, used ordinarily at ends of both single and double curves and at intermediate points and on double-track curves.

Feeder Clip—(Feeder clamp)—Clamp with a device by which a feed wire may be connected to the trolley wire.

Feeder—A wire usually insulated, used for transmitting current from the power station to the mains or the trolley wire descent.

Mains—Wire usually insulated, serving for the distributing of current from the feeders to the trolley wire through tap wires.

Tap Wires—Wires to convey current from feeders or mains at the pole to a near point of the trolley wire.

Trolley Wire Section—(Trolley section)—A length of one trolley wire with or without branches, but continues electrically.

Line Section—A part of the overhead conducting system, so insulated from other parts as to permit the supply of power to be separately controlled.

Section Box—A box containing section switches and fuses used for control of a trolley section or line section.

Rating of Motors.—I quote from the paper referred to as follows: It must be borne in mind that an electric motor, like any other machine, a man, for instance, is capable of performing work at widely-varying rates and widely-varying efficiencies, and with widely-varying factors of safety with respect to indefinite continuance of such a rate of work. It should further be borne in mind that an electric motor in particular is known to do its maximum rate of work when its efficiency is only 50 per cent.; that is, if 20 h. p. represents the maximum rate of work, then 40 electric h. p. will be required to perform this work.

The first condition, which should be connected by implication with any rating whatever, is this: That the machine in question shall be able to perform its rated work indefinitely and under any condition of atmospheric temperature. There is, of course, room for honest differences of opinion in regard to this point. There is again room for honest differences of opinion in regard to the efficiency with which a motor can do its rated work.

In spite of the fact that many objections may be urged against any suggested method of rating, that which is preferred by your committee and by many persons consulted in regard to the question is this: That a motor shall be known as to its capacity by the horizontal effort which it can apply to a car at a speed of 10 miles per hour, the standard 33-inch wheels above recommended being used on the car, and whatever gearing may be preferred by the manufacturer. It is plain that the horizontal effort that may thus be produced from a given motor whose armature is running at a given speed, may be made to vary by this change of gearing, but it has been thought best to consider the motor and its gearing as one piece of mechanism. While this recommendation would at first involve the use of two terms in the name of a motor, namely, horizontal effort and speed, the term for speed would soon disappear after it has become generally understood to be 10 miles per hour. Thus for the present, calling a given motor 600 x 10; this meaning that at a speed of 10 miles per hour the motor in question will develop a horizontal effort of 600 pounds. Later, however, the same machine would be satisfactorily designated as a 600-pound motor, the standard speed being taken for granted. At the same time as street railway men begin to go into sububan enterprises, in which higher speeds than those now familiar must be attempted, it will be easy to revive the expression for the speed at which a motor is rated, and we may thus expect to see motors described as 600 x 20, 600 x 30, etc. This high speed extension of electrical motor work, and especially its extension in the same hands as those now directing ordinary street traffic, makes it especially important that some rating should be adopted which will take speed into account, as otherwise confusion will inevitably result. It goes without saying that much remains to be told concerning a motor after its horizontal effort at a given speed shall be expressed, and a part of the recommendation of your committee is that an implied part of the rating of a motor lies in this, that it shall be able to perform its rated work continuously without a rise of temperature exceeding 75 degrees C. over the atmospheric temperature.

In regard to the efficiency, desirable as it is to be informed on that point, it seems too difficult to be involved in any rating which shall be frequently and properly used.

Another method of rating motors which is presented as the second choice of your committee is as follows: That two terms should be used, one giving the horse-power of the motor at which it can work continuously at a safe temperature, the other its maximum horse power. As has been explained, it is a feature of all electric motors that their maximum rate of work is done at a 50 per cent efficiency. Nothing is more essential to be established, therefore, than the maximum work the motor will do. Following this method which was suggested by Mr. Chas. A. Lieb, a given motor might be known as 15 x 35 or as 20 x 40, etc., concerning the first machine named, it being understood that it could do 15 h. p. of work all day long without undue heating, but under stress it could peform work at the rate of 35 h. p., the efficiency being at once known to be down to 50 per cent. It would also be understood, and go almost without saying, that the motor would be unable to do 35 h. p. of work continuously; indeed it would be expected to perform such a rate of work safely for only a very short time, say from two to five minutes.

In conclusion, while urging that all definite action possible shall be taken on the recommendations now made, we further urge most strongly that steps be taken to carry on permanently the work of standardizing, especially the work of standardizing the nomenclature and dimensions, since in regard to these there can never be any cessation of demand. To further this object we recommend that this Association employ a salaried official to be known as the statistical secretary or clerk; and that such employee shall give his whole time to the obtainment of data bearing on the work of the Association.

STANDARDIZING OF ACCOUNTS—ACCOUNTING METHODS AND STATISTICS.[1]

BY H. I. BETTIS.

THE ultimate object of all accounting is to ascertain with accuracy the amount of net income after all operating expenses and fixed charges have been paid. With this object in view, and no other, the art would be reduced to a very simple profit and loss account, debited with all expenses and credited with the entire income; but the owners and managers of our street railway properties for many reasons desire some further information than this. It is not sufficient for them to know that their road has a certain income, or that the expense has reached a certain amount. They desire to know many things in addition to these: What was the source of income; how many miles of track they have; how many cars; how many trips those cars make; how many passengers they carry. What other sources of income were there; what was the expense of operating the road; what portion was simply for the transportation of the passengers; how much was paid for motive power; for repair of cars; of apparatus; of track; buildings, etc., etc.; has anything been expended in construction, improvements or betterments.

Having all this information well in hand, the owners and managers can determine more readily wherein the expenses have been too large, and have thereafter a basis upon which to calculate their future operations. Moreover, what is of incalculable benefit, they can compare the cost of operating expenses of other lines throughout the country.

In the case of the steam roads of the United States the Interstate Commerce Commission has caused to be compiled a *Classification of Expenditures* and certain rules for their guidance in making the annual reports to the Government. Most of the railroad commissions of the several States have adopted this classification, and nearly all the railroad companies use the same in their accounts. It is quite probable that in the near future the Interstate Commission may extend its jurisdiction over the street railway companies, and in that case would compel them to adopt a uniform system of accounting as a basis.

This committee will not attempt to prescribe a set of rules and reports, but only to suggest certain distinctive lines which we believe should be followed in the future, when deciding upon a basis for accounting statistics.

Division of Expenses.—We are all agreed that it is essential for the expenses which add to the present or future value of a property to be separated from those which do not, and that the three great divisions should be: 1, transportation expenses; 2, maintenance; 3, construction. This established, the various subdivisions may be few or carried to infinity, but the final results are necessarily the same.

---

[1] Addendum to report of committee on standards.

The differences between these divisions are as follows:

1. *Transportation* expense is simply the expense of transporting the passengers, and includes nothing whatever expended upon the property. Under this heading we should find wages of conductors, drivers, gripmen, motormen (engineers and firemen on dummy lines), fuel, provender, lubricants, wrecking, etc., etc.

2. *Maintenance* expense is the expense of keeping the properties in their original condition, and consists of the amounts expended upon repairs of track, buildings, cars, power plant, engines, etc., etc.

1. *Construction* expense is such as adds to the value of the original plant, such as additional buildings and machinery, new tracks laid, less the value of old ones taken up, etc., etc.

Improvements and betterments should also be included under the head of construction, that is, for such portion as the property is improved over the first cost.

One question deserving your consideration is that of taxes, and whether it should be included in the operating expenses or not. I have noticed that the majority of the roads do now include it, while a few deduct it from the net income after operating expenses.

Material.—Another point we would suggest is to recommend the accounting for material as closely as possible. It is the practice upon many roads to keep no account of material purchased and kept in stock for future use, but to charge all material purchased to expense, whether used at once or not. It must be perfectly clear that when material is purchased, there is no decrease in the assets of the company and consequently no expense. There has been simply an exchange of cash for material. The expense does not occur until the material is used.

It is absurd to charge to the expenses of one month all the bills paid in that month, or the bills contracted in that month, when the material covered by the same may have been used long ago, or may be in stock and for future use. Material used represents from 30 to 40 per cent. of the expenses of operation, and yet on the majority of our roads it receives no attention whatever.

Unit for Comparison.—It has been suggested that we adopt as a unit for comparison *the car mile*, especially in regard to motive power, and consider the single truck with double motor car as the Standard, double-truck cars to be equal to two trains of two cars each. It is difficult to say what should be the unit, whether it should be the car mile, the passenger or neither. When we consider the vastly different conditions to be contended with on the various roads, in the shape of grades, distances from power house, amount of traffic, etc., we can hardly settle upon any factor for a unit. It may be decided that the best results for comparison will be found by comparing the percentage which operation bears to gross income.

Future Work.—I would advise for the continuance of this work that a committee, selected from the accounting officers of roads in this association, be appointed to prepare a standard classification of expenditures, with blanks for statistical reports to be referred to the next annual convention; the same to be previously circulated among the members of the Association, in order to obtain the fullest possible criticism and examination at the convention.

RELATIVE COST OF OPERATION OF HORSE, CABLE AND ELECTRIC ROADS.[1]

THE work which the committee had to perform was to ascertain from leading horse roads, cable roads and electric roads, such information regarding the cost of operation of each, as the existing methods of accounting in each case made possible. They recognized in the early stages of their work that any attempt on their part to shape the accounts of the companies to suit the purpose of the committee would be fruitless, for reasons which must be obvious to all. A series of questions were framed comprehending the information desired, and with such subdivisions of operating expenses, as it was thought would meet with most ready reply. Many of the replies sent to the committee were given for the personal consideration of the committee alone, and not for publication or public reference in any way. We have, however, chosen a few of the representative roads of each class, and have tabulated the replies in such a way that reference can be made to them by number if desired.

A comparison of the reports from these roads does not reveal the characteristics which we should expect to find. We see results which are as varied as could be imagined. Why should cable road No. 1, earning only 18 cents per car mile, have within eight cents per car mile as much to divide among its stockholders as road No. 3, having nearly 12 cents per car mile more receipts? Let us refer to the reports of these two roads and make a few comparisons.

TABLE NO. 1.

Operating Expenses, etc., of Eight Cable Roads.

No.	Average No. of grip cars operated daily.	Average No. of trail cars operated daily.	Daily mileage of grip and trail cars.		Receipts per car mile, including mileage of trail cars.	Fixed charges per car mile.	Interest on funded debt.	Taxes, tolls—State, county and municipal taxes, except water taxes.	Gross operating expenses per car mile, exclusive of fixed charges.	Maintenance of roadbed and track.	Maintenance of cable rope and underground machinery.

....	....	2.360	2.380	2.840	6.900	2.210	6.6100	20⅛	Slack	1.21

The first noticeable difference in the condition under which the two roads operate lies in the fact that road No. 1 operates daily an average of 298 trail or tow cars, while road No. 3 operates only grip cars. Road No. 1 operates 1.54 tow cars for every grip car operated, or a daily mileage of 203.2 for every train of one grip car and 1.54 tow cars to every 100 miles made by a train of one grip car only, which road No. 3 operates. Now if the expense of operating increased *directly* as the mileage, whether made by grip or by tow cars, a direct comparison of these two roads would be possible; but such is not the case. Road No. 3 is evidently at a disadvantage. The same difficulty occurs in the comparison of certain electric roads with one another.

A very excellent method of correcting this error has been formulated by Dr. Cary T. Hutchinson, and is here presented by his kind permission. It is evident that what is wanted is a formula which will represent the ratio of cost per car mile, as ordinarily counted, to cost per motor car mile, for any item of expense.

Dr. Hutchinson's method is as follows:

Let $t =$ No. of miles a train of two cars run per day.
" $m =$ " " motor car alone runs "
" $a =$ cost per train mile for any special item, *e. g.*, cost of fuel.
" $b =$ cost per motor car mile—the same item.
" $N = 2t + m$ equals "Car Miles" as ordinarily counted.
" $r = a/b$ equals ratio of cost per train mile to cost per motor car mile for any given item.
" $c =$ cost per car mile, counting trailers same as motor cars. This is the figure ordinarily given.
" $c\,N =$ total cost of operating line per day—for that item.

Then $a\,t + bm = c\,N$ for any item of expense.

but $a = br$

$$\therefore\ b\,(tr + m) = c\,N$$

$$b = \frac{c\,N}{t\,r + m}$$

$$b = \frac{c}{r\frac{t}{N} + \frac{m}{N}} \qquad (1)$$

$$a = b\,r \qquad (2)$$

Now $\frac{t}{n}$ and $\frac{m}{N}$, the ratios of train and motor to total mileage, are known.

Then r must be determined for each item of expense.

Table Showing Statistics of seven Electric and one Cable Road.

Therefore, for

1. $b=1.14c$, $r=1.5$
2. $b=1\ 36c$, $r=1$
3. $b=1.18c$, $r=1.4$
4. (a) and (b), $b=1.18c$, $r=1.4$
(c) and (d), $b=1.38c$, $r=1.$
5. (a) and (b), $b=1.38c$, $r=1.$
(c) $b=1.25c$, $r=1\ 25$
6. (c) $b=1.14c$, $r=1.5$
(b) (c) (d) (f) and (e), $b=1.25\ c$, $r=1.25$
7. $b=1.38c$, $r=1.$

These are the figures used in computing cost per motor car mile in the case of the No. 2 railway. No other line used trailers.

"I take for r the following values:

"*First.*—Maintenance of roadbed and track, $r = 1.5$; although there are two cars instead of one, yet the trail car is by no means as hard on the rails as is the motor car.

"*Second.*—Maintenance of line, $r = 1$. It is the same whether there is or is not a trail car.

"*Third.*—Maintenance of power plant, $r = 1.4$ Because I have found by experience that under average conditions a train requires about 1.4 times the power of a motor car, and maintenance should be assumed proportional to power developed.

"*Fourth.*—Cost of power. (a) and (b) fuel and supplies, $r = 1.4$, as above. (c) and (d) attendants, $r = 1$. Because for a good size plant no more men would have to be employed in the power house if all the cars hauled trailers; the force required is not proportional to the output, but is constant within pretty wide limits.

"*Fifth*—Maintenance of rolling stock. (a) and (b) repairs to motors, $r = 1$. (c) repairs to cars and trucks, $r = 1.25$. Repairs to trail cars are very much less than to motor cars.

"*Sixth.*—Transportation expenses. (a) carmen, $r = 1.5$; three men on a train and two on a motor car. (b), (c), (d), (e) and (f) may all be bunched at $r = 1.25$.

"*Seventh.*—General expenses, $r = 1$."

Referring again to our table of statistics: No. 1 road expends .925c. per car mile for the item of cost of power, and No. 3 road expends for the same item, 1.07c., and this, notwithstanding the fact that road No. 3 only pays $1.21½ per ton for fuel, while road No. 1 pays $1.47 per ton.

Using for r the value assigned above for cost of power, 1.4, our equation reduces to $b = 1.07$c., or in other words .925c. should be multiplied by 1.07 to bring it on a basis of comparison with No. 3 road. This gives us .99 c. for No. 1 road as against 1.07c. for No. 3. The difference which still exists may be accounted for either by reason of a possible difference in the efficiencies of the two power plants, or by the possibility that one road may operate more cars to do the same amount of business than the other road.

This method of comparison can be used satisfactorily for any roads, cable or electric, providing the necessary data has been obtained as to motor car miles and train miles, and providing experience and careful observation have enabled the investigation to assign approximately correct values for r, which will differ in different cases. But there are yet many discrepancies to explain, for which we must seek other reasons. Why should the gross operating expenses of No. 3 electric road exceed the gross receipts per care mile of No. 4 electric road by nearly 100 per cent., and yet both roads still have a fair percentage of their receipts left for dividends? No. 4 road is a small road, and No. 3 is a large one, but we cannot argue that small electric roads have a better chance for profits than large ones. It is fair to assert that study of No. 3 report would lead to the conclusion that either there is more in the road than is brought out of it, or that the only thing that justifies the outlay of 25½c. per car mile (trail car mileage included), is the receipt of over 40c. per car mile, to do it with.

For a comparison of an average cable road with an average electric road, let us take No. 3 cable road, and compare it with No. 7 electric road. The cable road has been shown to be something better than the average, and the electric road is known to the writer to be at least up to the average. These two roads afford us a better opportunity than any other two which we might select, for the following reasons:

1st. Both are located in the same city, where climatic and other local conditions are the same.

2d. Both roads are of the same magnitude.

3d. Fuel and labor cost the same in each case.

4th. Neither road operates trail cars.

The cable road has the advantage in route as to grades and curves; otherwise, the roads offer excellent opportunities for comparison. It might be added that the investment in each case is up to the average, that is, is not extravagantly large, and yet is ample for the business transacted. Each road may be regarded as typical of its class. We see, upon examination, that the cable road has the greater fixed charges by 1.7c. There is a difference of 1c. in the gross receipts in favor of the cable road; one cent of which may be said to be due to the larger gross receipts; but resorting again to the comparison by "figure of merit," we find a ratio of .00015 to .00020, or nearly 3 to 4 in favor of the electric road. This simply means that each dollar invested in the cable road will earn .00015 in one day, whereas each dollar invested in the electric road will earn .00020 in one day. The total investment in the case of the cable road in this case is 2⅛ times the total investment in the case of the electric road. The capital stock alone, exclusive of bonds of the cable road, is 2.4 times the capital stock of the electric road. What is our conclusion from these facts, or can we draw a conclusion on which we can stand? We have not been conservative in our statements thus far, but are, of course, not infallible. "One swallow does not make a summer"—nor do the examples we cite determine the whole matter once for all. The cable road has its place firmly established in the transportation business of the Pacific Slope, and we, who are unacquainted with the conditions met with there, cannot presume to say that the electric railway would do the same work better and more efficiently. We are tempted to say so, but the interests concerned are too great to be trifled with in so dogmatic a manner. The cable roads have their methods pretty well digested, and their figures are, as a rule, reliable. The electric roads are as yet, with few exceptions published in this paper, in the dark as to what they are doing—except that they have enough left to satisfy stockholders—in fact 89 per cent. of the electric roads heard from report dividends from 5 to 12 per cent.

We believe that cable road practice has reached the stage where but little room is left for improvement. They have been developed, improved and operated by the best engineering skill which the country affords. Nearly all are on a good dividend paying basis; but whatever the past experience of the two systems has been, or whatever the present status of the two may be, we are only voicing the convictions of well-informed engineers, when we say that electric systems will continue to increase in efficiency (by which is meant earning capacity), until all rivals are distanced, and only one method of rapid transit is recognized —the electric car.

EXPERIMENTS ON THE EXPANSION OF CONTINUOUS RAILS[1]

BY A. J. MOXHAM.

THE author introduced his subject by a short history of the evolution of the street railway joint, the problem being finally attacked by supplying a device based on the theory of stopping all motion. In this, two points were essential:

First, to hold the rail against motion by means of the fastening bars; to which end it was necessary to,

Second, hold the fastening bars against motion by means of the bolts.

The joint of to-day is structurally stiff, heavy enough to take up the jar of the blow without transmitting it all to the nuts, a yielding fit that tends to counteract all motion, and large bolts, carefully located with a view to vibration. In itself good, and as it now stands, to a certain extent, capable of economical use, and far ahead of its brother on the steam road, even of the heaviest construction. But even so *it will not do.* If not, "What then?" There is but one answer; *no joint at all.* While apparently a bold suggestion, it is at least worthy of thought and discussion. That the rail can be made continuous by mechanical means we know, but what of expansion and contraction? *We will do without it;* and that we can do so, the sequel, the author thought, would show.

To the credit of Mr. Philip Noonan belongs the first practical idea of a continuous rail. His theory, in a nutshell, may be described as gripping the rail at one end and permitting the wave motion or flow induced by passing trains to be, so to speak, rolled out before the train wheels, into a tension device that within certain limits holds what it gets. He provides against danger of rupture by a spring device which limits the strain. He put his ideas to a test, built a considerable stretch of track (some three miles) on the Lynchburg and Durham Railroad, at or near Gladys Station, Va., and it to-day is in successful use. Expert investigation and report indorses it in all essential particulars, though it is perhaps questionable whether the fastenings he used to make his rail continuous are strong and rigid enough to prohibit all yield. For details, those who care to investigate may be referred to a pamphlet on the subject, that can be obtained by addressing the inventor at the above named place.

At a glance, the problem of a street railway differs from the steam road in that the former is surrounded by the roadbed, while the latter is, at least, to a great extent, exposed. The effect of the surrounding roadbed is twofold. First, by its great surface friction, it tends to hold the rail against change, stops all wave motion, and second, it to some extent modifies the temperature. The problem was to find a measure of value for both. To this end the following experiment was made:

One rail in a section of track was so connected that it was in reality a continuous rail. One side of the track was taken instead of both, because it was thought the parellelism of the adjacent rail would at once indicate changes that were expected to occur, which perhaps other measurements might fail to disclose. The length was 1,160 feet, and the profile one that embodied level track, up grade and down grade. As the track was laid and in use, it was determined that it was best to make the rail continuous by a joint rigid and stronger than the rail, so as not to have to remove the whole roadbed. This because the roadbed, which was macadam, had become solidly packed and represented normal conditions hard to obtain if once disturbed. When the experiment was made it was thought questionable whether the rail, when prevented from expansion and contraction, could be at all restrained by the roadbed; hence all the restraining power offered was to be retained. At the end of each separate rail the usual one-fourth of an inch had been left for expansion. This was filled by a carefully measured dog, made of the same section as the rail, cut to fill the space tightly and then driven into place.

As the joints were to be stronger than the rail itself, and for connection body-bound, machine turned bolts were decided upon. The two side bars were of steel, 4 x 1¾ inches thick, and 5 feet 4¼ inches long. The body-bound bolts were 18 in number, and 1¼ inches in diameter.

---

[1] Abstract of a paper read before the American Street Railway Association, at Cleveland, Ohio, Oct. 19–21.

To insure an absolute fit was deemed a necessity. It was done as follows: A number of jigs were made having a hardened steel guide for the drill. With this the bars were drilled in pairs, and as drilled each bar carefully tested by the standard. The holes were drilled $\frac{1}{32}$ of an inch smaller in diameter than ultimately needed. The roadbed surrounding a joint being removed, one bar was clamped to the rail, and the holes (also $\frac{1}{32}$ of an inch small) were drilled through the web, using the bar as a guide. After the temperature of the parts was equalized, the adjoining bar was then adjusted and a rose-bit reamer carefully worked through the three holes. As quickly as one hole was completed the gauge was taken, and one of a series of machine bolts (previously turned to a standard slightly large) was accurately turned for this special hole; and so to completion. Each bolt was a driving fit. It took 24 hours to properly adjust each joint. The track was thus made continuous.

At five points along the line heavy stakes were firmly fixed in the ground, one on each side of the road, in the top of which were set small wire nails. A thin but strong cord was tightly stretched from stake to stake, the tops of which were several inches above the top of the rail. Directly underneath this line a mark was made on the head of the rail with a cold chisel. Measurements were taken from the stake to the chisel mark, and from the top of the rail to the tightly stretched cord. Observations were taken at these five points, in the manner indicated, throughout the whole summer.

The work was started on the 19th of March, and finished on the 25th of April, 1892. The average temperature during the work was 43.04°, the maximum 81° and the minimum 10°. The section of rail used in the track is of the girder type, 6 inches deep, weighing 78 lbs. to the yard. The rail is fastened to the ties by means of tie-plates, and the gauge is preserved by tie-rods spaced 10 feet apart. The ties are spaced 11 to 30 feet apart, and the roadway is excellent macadam.

Anticipating the unknown, provision was made for a possible sudden stoppage of the line, by means of portable connecting tracks kept in readiness. In order to further explain whatever might occur, careful preparations were made to read the temperature of the rail at different parts above and below ground during the experiment. As the rail was in use, this was done by a special rail in the adjoining roadbed, and in order that the scope of investigation should be fully complete, the temperature was continuously taken at the head of the rail, at the lower flange of a 6-inch rail, or a 7-inch rail and of a 10-inch rail, or its practical equivalent, a 10-inch I beam. Simultaneously readings of temperature were taken as follows: Air in the shade; air in the sun; roadbed at a depth of 7 inches; roadbed at a depth of 10 inches.

A slight analysis of the tables compiled will suffice to prove to the practical railroad man that for all ordinary purposes, the rail may be assumed to be subject to nearly full air temperature, and that the roadbed will not suffice, as has been believed, to keep the rail temperature virtually regular. Steel is a far better heat conductor than earth, and the tables show that the whole rail (flange as well as head) closely follows the air temperatures. Readings taken over a long period, night as well as day, every 15 minutes (in Table No. 6) give the whole kaleidoscope of changing temperature. With this fact before us one element of doubt has been removed; but it also proves that the heating of the sun in the day, and the cooling of its absence at night, leaves the expansion and contraction most certainly there.

Now for its effects. The experiment has proved absolutely and beyond cavil, that it is restrained and held by the surface friction of the surrounding roadbed. From first to last, from a temperature of 22° below freezing point (or 10°), to a temperature of 89° above freezing point (or 121°), extending from March to August, there was *absolutely no movement of the track out of place.* Even at the ends was this true; proving that not only will the roadbed hold the track as a complete structure, but that it will do it consecutively. Once bedded, it will hold a rail 10 feet or 30 feet, as well as one 1,100 feet. On this point there is no room for error. The expansion in 1,100 feet, if not neutralized, would equal 5¼ inches, under the conditions here stated, and 5¼ inches would throw the rail out of line 14 feet, if it were held at the ends and permitted to bow in the centre. An expansion of one rail would mean about 6 inches in 30 feet out of line. The query arises, "What has become of it?" It is existent, and, like all force, it would flow to the point of least resistance. In the case of a street rail, buried in the roadbed, it is reasonable to believe this point is in a minute enlargement and reduction of the sectional area of the rail.

As to its effect upon the steel: Experts teach us that a variation of 7° in temperature, if held, would subject the rail to a stress of 1,000 pounds per sq. inch Taking a track laid at the low temperature of 40° and subject to a maximum of 120°, or a variation of 80°, the stress is equal to less than 12,000 pounds per square inch, much less than the elastic limit, and less than the strain put upon an ordinary bridge, or similar structure. It would therefore appear that the effect on the steel would be harmless.

On the face of it, therefore, there is nothing to prevent us abutting our rails, and this is but the prelude to an absolutely continuous track—*one without joints*—the rails welded by electricity, or otherwise connected one to the other, up to such lengths as may be deemed best.

As to its practical application, many precautions suggest themselves. It must be remembered that a track so laid will be like a huge spring under tension, absolutely safe and harmless when restrained by the roadbed, but ready to spring like a shot from a cannon if, while in this condition, the roadbed be removed. The part of common sense would appear to be to limit the length of a continuous rail to, say, five hundred or a thousand feet, with specially devised expansion joints at these intervals, or if desirable to take up the paving for repairs on a very short piece, the following would be effective: First remove only a foot of paving, then with a hack saw cut out, say, six inches of rail, thus removing the tension or compression, as may be. This done, the rest of the roadbed could be removed, starting from the cut part of the track, without danger. Be this as it may, it should be borne in mind that chained lightning is not a nice plaything, and therefore a lightning conductor is sometimes handy.

One important saving that would be effected by a "track without joints" would be in the weight of the rail. A rail of 100 pounds per yard is to-day in use, and next year will be extensively used. Perhaps without their knowledge, the cause of this has been the street railroad men's dearly bought and sad experience with joints. The joint being defective, the effort has been made to secure such stability of track as to relieve the joints by means of a heavy rail. In a 100-pound rail there are but 30 pounds of wearing surface, of which not more than 18 pounds can be used before the rail will have to be thrown out; therefore, there will be 82 pounds unused. For mere stiffness and rigidity, a 66-pound rail, if supported by the proper number of cross-ties, will answer every engineering demand, even of electric cars at high speed. Anything over this goes to the debit of "bad joints."

ECONOMY OF MACHINE SHOPS FOR ELECTRIC STREET RAILWAYS.[1]

BY JOHN H. BICKFORD.

THERE is great lack of uniformity in the operation of roads, and one can find hardly two which are following the same course, as regards repairs and renewals to motor equipment. The one thing to prove is, whether there is economy in maintaining a machine shop when there are so many manufacturing and supply companies which can furnish us with every conceivable thing we want (and many more we don't want) at short notice; and the local machinist stands ready to do our work at a price varying from fifty to seventy-five cents per hour for first-class workmen (and double price for apprentices).

After having bought the best apparatus, we must provide means to take care of and repair it, and the first thing to do is to provide competent help. On this last point hung the key to success. The author strongly advocated the employment of skilled mechanics, that is to say, men who are skilled in their particular branches, such as skilled armature winders, linemen, etc., in contradistinction to the machinist, who is usually so termed.

Skilled help being thus found to be necessary, the next thing was to provide a suitable equipment for maintaining the road and all apparatus in good condition, and for this purpose a repair shop was, in his opinion, indispensable. How far should the equipment of such a machine shop be carried? Should it be made a manufacturing establishment? There was surely a point where the line must be drawn. Would it be well to go no further than the mere making of repairs, or would it be better to go a little further and manufacture supply parts? The author here referred to the long experience of steam roads who had found it economical to maintain complete repair shops with competent master mechanics at the head.

In order to arrive at the results obtained in actual practice, the author sent out circulars requesting information on the points referred to and received replies from 66 companies operating electric roads.

Among the answers received he found many things to strengthen his belief that it is economical to maintain a machine shop, not only for repairs but for the manufacture of supply parts. It turns out to be a fact that no less than twenty-four roads are maintaining machine shops, doing all their own repairs and manufacturing many supply parts. They say unhesitatingly that there is economy in so doing. They give as their reasons: First, that they can *make* better material than they can *buy*; that they are perfectly familiar with the requirements and conditions of the business; they are operating the roads and are in a position to know just what is needed, and are better able to judge of the strength and durability of the apparatus than those who have never been in a similiar position. Was not this a natural consequence?

In presenting this he did not mean to cast reflection on the earnest efforts of his good friends in the manufacturing business, but he must say from personal experience that there was much material on the market to-day that was not up to the standard. Why? Simply because the makers of it do not understand thoroughly the requirements of the business. Some may be unscrupulous enough to put goods upon the market just for what is in them for a while, regardless of their stability; but he hoped this was not the case, for surely we had much rather believe to the contrary.

---

[1] Abstract of report submitted to the American Street Railway Association at Cleveland, Ohio, Oct. 19-21.

A second reason given is, that there is a saving of from 25 to 50 per cent. by manufacturing the majority of parts.

From this and the experience of steam roads, the author concluded that there must be economy in machine shops for electric railroads.

The author then gave a classification of the answers received as follows:

10 *Cars or Less*.—Received answers from 16 roads; 14 of these buy all supplies and repair parts, and have not a machine of any kind; the other two have a drill press, small lathe and blacksmithing outfit.

10 *to* 20 *Cars*.—Received answers from 13 roads; seven of these have partially equipped machine shops, do all ordinary repairs, and manufacture many parts for renewals; the other six have not a machine of any kind.

20 *to* 30 *Cars*.—Received answers from 10 roads; six of these have well-equipped machine shops, do all repairs, and manufacture most parts for renewals; the other four have not a machine of any kind.

30 *to* 50 *Cars*.—Received answers from six roads; of these one has not a machine of any kind; one has only a wheel press; two have a drill press, lathe and blacksmithing outfit; the other two have fully equipped shops and do all repairs and make nearly all supply parts.

50 *or More Cars*.—Received answers from 12; two of these have only a drill press, lathe and blacksmithing outfit; nine have complete shops equipped with machines of all kinds and manufacture about everything necessary to maintain the equipment; one has a very extensive manufacturing establishment, outside of a complete repair shop, and also maintains a brass foundry. The remaining roads from which answers were received had no definite information to give. One or two said that they were getting ready to establish shops, and others were undecided what they would do.

Out of the 66 roads heard from, 36 were winding their own motor armatures and field coils, and the cost of armatures varied from $17 the lowest, to $75 the highest; the average was about $35, including all labor and material.

Fifteen roads had wood-working machinery, consisting principally of saw-table, band-shaw, surface-planer, and mortising machine. Seven roads are cutting their gears, but some of them find it no cheaper than to buy. They think, however, that the work and material are better, and for that reason it pays them. Others make all gears and think there is a saving in cost. Eight roads are building their cars, while several are rebuilding old cars, but make no new ones.

The author then gives a few of the prices for which supply parts are being made in the shops of the different roads. These figures are an average taken from 11 roads which are using Sprague, Thomson-Houston and Westinghouse double-reduction motors.

Refilling commutator (copper bars) $18.50; two halves armature bearing, Thomson-Houston, $3.96; single Sprague, $1.85; two halves axle bearing, $3.50; brush holder, $1.35; rocker arm, Thomson-Houston, $1.00; Sprague, $3.00; internal shaft (steel), Thomson-Houston, $10; Sprague, $3 00; internal pinion (steel), $4.20; internal gear, $3.88; axle gear, $5.66; armature pinion (steel), $3.58; trolley wheel (brass), $1.00; line frog, $1.90; clips for line hangers (brass), 15 cents; to bore and press on 30-inch wheel, 95 cents.

The average price for which roads sell scrap car wheels is $13.65 per gross ton; the lowest being $8, and the highest $20. Some roads have kept no account of cost of making repair parts, and therefore could give no prices. It is unnecessary to say that it would be wise to do so. With but two exceptions, the single-reduction costs less to maintain.

Nineteen roads are employing an electric engineer, and four have a superintendent and electrical engineer combined.

The results of these inquiries fully coincided with the author's opinion previously expressed, that there is economy in maintaining repair shops, and even manufacturing supply parts. Small roads, of course, might not find it profitable to go to this length, but many would find it to their advantage.

The report then gives the following list of machines which the majority of roads having machine shops are using:

One 20-inch swing, 10 foot bed, engine lathe; one 16-inch swing, 6-foot bed, engine lathe; one 16-inch swing, 6-foot bed, speed lathe; one 24-inch x 24-inch iron planer; one No. 3 or No. 4 Universal milling machine; one 45-inch upright boring mill; one 24-inch upright drill press; one 12-inch upright drill press; one 100-ton hydraulic wheel press; one open die bolt cutter and nut tapper; one medium size shaper; one tool grinder; two forges with power blower; one set of emery grinders; one grindstone; necessary bench tools and fittings for machines; one 10 h. p. motor to run machinery. Of course roads with a great number of cars would need to duplicate some of these machines, and add some others not mentioned.

Finally the author advocated the employment of a thoroughly competent electrical engineer, not one of the self-styled "electricians," but one who has a theoretical as well as practical knowledge of mechanical and electrical engineering.

IS A STANDARD RAIL HEAD POSSIBLE?[1]

BY JOHN T. OSTROM.

IN order to ascertain the prevailing practice, the author addressed inquiries to manufacturers from which the fact was developed that wheel treads vary from 1⅛ inches to 5 inches. Flanges from $\frac{7}{16}$ to 1½ inches. Rail from 16 pound T to 98 pound girder. One council unanimously requested the road to take up all girder rail and lay T rail instead Another specified both form of rail and weight (groove girder, 77 pounds), while others specify a rail of a particular manufacture, a rail with a stated width of wagon tram, etc.

Suggestions as to standard vary as much as conditions. On one point only all seem to agree, and Ohio voices the general sentiment, "Tram rails no account for anything or anywhere." One road writes: "There should no rail but a T rail be used where the city authorities will allow it." Another, "Plain T every time, under all circumstances of paving or traffic." Another, "There seems to be a popular prejudice against T rails for street work which is exercised wholly without reason; and, so far as the T rail for the very best service goes, there is no chance for argument."

Against these are suggestion for side bearing rail, with various widths of wagon flange and for centre bearing and groove girder rails; 88 companies operating 1,083 miles of track, suggest T rail; 60 companies operating 1,101 miles of track, suggest girder rail; 45 companies operating 1,243 miles of track, suggest a section of girder rail deep enough to be spiked direct to tie in paved streets.

There are at present, besides the various sections of the rail, over 90 sections of girder rail now on the market, with 15 different widths of head between 1½ inches and 2¼ inches. These rails have 10 variations in flange room or dip, from ⅞ inch to $1\frac{3}{16}$ inch.

The necessity for a standard recognized, is it possible to devise one that can be accepted as such? In response to inquiries already referred to, the author received replies from 306 roads, operating cars on 4,347.8 miles of track. Twenty of these roads operate with steam motors over 155 miles of track; 29 with cable motors, over 328 miles; 99 with horses, over 1,117 miles; 198 with electricity, over 2,748 miles; 59 have 625 miles of stringer rail track; 197 have 1,532 miles of T rail track; 146 have 2,190 miles of girder track.

This mileage he thought would justify him in assuming that the above reports may be reasonably taken to represent the condition of the street railway situation of the country to-day. Two hundred and sixty-four roads reported width of wheel tread on 3,937 miles of track. These varied from 1½ inch to 5 inches, in 14 different widths, 2 inches, 2¼ inches and 2½ inches being used in the majority of cases; 170 roads, operating 2,942 miles, use 2¼ inch wheel tread or less; 56 roads operating 568 miles use 2½ inch tread.

One hundred and forty-six of the electric roads use three-quarter inch wheel flange and under on 2,244 miles of road, and 24 roads use seven-eighths inch flange on 256 miles of track. By combining these roads, increasing the depth of wheel flanges below three-quarter inch to that point, and cutting down the seven-eighths inch flange to three-quarter inch, we would have 2,500 miles of track using our standard, or 95 per cent. of reported electric track.

The author finds that the wheel tread that most nearly approaches the necessities of the street railway world of to-day is a 2¼ inch tread, and the wheel flange one three-quarter inch deep. The apparent need is for a rail designed to carry such a wheel. Such a rail should have, in his opinion, a head flat, or nearly so, $2\frac{5}{16}$ inches wide, with a curve not over one-quarter inch on the gauge line corner, with a dip of one inch to the wagon flange in side bearing rails, and 1⅛ inch to bottom of groove in groove rails. The width of head and the gauge line curve can be made alike in both T and girder rails. Distance from centre line of web to gauge line in girder rail five-sixteenths inch. The author's reason for making the groove deeper than dip in side bearing rail, is that in the latter both head and flange are subject to wear, while in the groove rail the wear is confined to the head of the rail until the wheel flange strikes the bottom of the groove. Such a standard rail head he believed to be perfectly feasible. Its adoption by the Association would materially simplify both the track and wheel questions. It would give to manufacturers a clear idea of what street railway requirements are likely to be, and enable them to have such rails as may be desired ready for next spring's business.

---

[1] Abstract of a paper read before the American Street Railway Association at Cleveland, Oct. 19–21.

The author also referred to a paper by Mr. Geo. W. Mansfield on "Rail Sections and Special Construction," read before the Massachusetts Street Railway Association, as containing valuable information.

A PERFECT OVERHEAD ELECTRIC CONSTRUCTION.[1]

BY CH. K. SMITH.

I GIVE only my ideas of how an electric overhead line should be constructed, based upon facts and information derived from personal experience and observation.

Iron or steel poles have proved to be the most desirable. I would therefore recommend the following: The poles to be of tubular iron, thirty-two feet in length, and made in three sections, in the usual way. The lower section should be at least seven inches in diameter, and the other two sections six inches, and five inches, respectively. The poles should be set in concrete, and at least six feet in the ground, and should not be more than 125 feet apart. The top of the pole should have about two per cent. of rake away from the curb, and should be fitted with a suitable pole clamp, so that the span wire can be easily adjusted to the required height, which should be twenty-two feet above the track. On top of the pole should be a malleable iron cross-arm to carry the feeder wires, and guard wire spans. This cross-arm should be insulated from the pole by means of a wooden plug inserted in the top of the pole. The insertion of the joints of the pole should be at least eighteen inches, and the joints should be made solid throughout their entire length by means of sleeves, or other contrivances. If these joints are not properly made, the poles will not stand the strain. For curves, or extra strain, there should be larger poles of the same make.

Span wires should be of No. 4 "B. W. G." silicon bronze wire, and should be fastened to pole clamps by means of insulated turnbuckles. Great care should be taken in insulating these turnbuckles from the poles.

All well-built lines should be sectional, and the trolley-wire should not be of too great a size, as it would then call for clumsy supports. As it is not the main current wire, it can be of a smaller size. I would therefore recommend No. 4 "B. W. G." silicon bronze wire, which affords sufficient carrying capacity, and has great strength and durability. Sections should not be of a greater length than two miles, and should be separated by trolley-breakers, of which there are now a number of good ones in the market. In cities and villages, where there is great liability of fires, it would be advisable to put trolley-breakers at shorter intervals. Trolley wire hangers and pull-off brackets should be of the lightest make possible, and still have the required strength and the very best insulation. There is a variety of such hangers and brackets now in the market.

As it is important to have as small a number of joints as possible in the trolley wire, it should be put up in mile lengths, and twisted splice joints should be made, and brass cone-shaped tubes slipped over the wire before the splice is made. After completing the splice, the larger ends of the tubes should be brought together over the splice and a little solder dropped through a small hole made in the tubes for that purpose, in order to keep the joint in place. Overhead switches, or switch-pans should be avoided, if possible, as they become a source of great annoyance. I would strongly recommend a double trolley wire for a single track road.

Great care should be taken in erecting the guard wire spans. They should be properly insulated from the cross-arm by means of a strain insulator, or something equally as good, and should be of at least No. 6 best galvanized iron wire. There should be two guard wires over each trolley wire at least three feet apart and four feet above the trolley wire. The guard wire must be well insulated from the guard spans; in case of other wires falling, this would be a great importance. Pull-off and anchor guy-wires or other wires for the same purpose, must be of the very best material, and of at least No. 8 galvanized iron wire.

Feed-in taps must not be more than five poles apart and should take the place of the trolley span wire at that point. They should be of at least No. 0 insulated wire. The trolley wire being sectional, it is necessary to run a feeder wire to each section. I would therefore recommend that the feeder wire be at least thirty per cent. larger than the occasion demands. It will be found that this is money well invested. The insulation on the feeder wire should be the best that can be procured, and I would advise using locust or iron pins with mica insulators or something equally as good, for the purpose of fastening the feeder wire to each pole, and great care must be taken to protect it from trees and other obstructions.

A cut-out box should be located on the pole at each trolley breaker, and should not carry a fuse. It should have the same wire running through it as there is on the outside. The fuses should be at the station, with amperemeter and cut-out switch for each section; then, in case of trouble on any section, the location can be easily seen, and that section cut out, if necessary, until repaired. Lightning arresters are of great importance on the line, and I would strongly recommend using them at least every thousand feet. They can easily be attached to the poles, and can be protected by means of a box.

In conclusion, I would say that no matter what expense is incurred for material, or care used in constructing, a good line cannot be ensured without a thorough daily inspection.

ANNUAL MEETING OF THE AMERICAN STREET RAILWAY ASSOCIATION, CLEVELAND, OCT. 19, 20 AND 21.

THE annual meeting of the American Street Railway Association was held at Cleveland, O., on Oct. 19, 20 and 21, with headquarters at the Hollenden Hotel, and exhibits at Army and Navy Hall, and meetings at the Y. M. C. A. The membership now includes over 200 roads, the attendance from which was very large. As for supply men, they were simply innumerable.

The convention was called to order on Wednesday morning at the Y. M. C. A. by Mr. John G. Holmes, president, and Mr. W. J. Richardson, the secretary.

An excellent address of welcome was made by Mayor Rose, who while praising street railroads, especially cable and electric, advised his hearers to deal fairly with the community in which each worked, and not to be too grasping as to franchises.

To this Mr. Holmes responded admirably, saying the course of his address :—

This city offers a fine opportunity to study practical street railroading. Here we see the most advanced ideas of construction, the highest development of the electric system, and a splendid new cable plant, as near perfect as capital, invention and engineering skill have been able to make it. And by the way of contrast and historical interest, we find a few horse car lines to remind us of the meetings a decade ago, when we used to grow excited over discussions of the relative merits of the horse and the mule as a street railway motor.

This is pre-eminently an electric age, and most of us believe that as yet we are only standing on the threshold. The horse and his half brother, the mule, are destined to disappear. The cable system, from its very nature and cost, must be confined to the thickly populated districts of large cities, but there seem to be no limitations to the electric railway. It leaps over the city lines wherever there is a large suburban town calling for rapid transit, it girds the summer lakes, it is forcing its way through the scenic splendors of the Niagara gorge, close beside the water's edge, and when the convention goes to California, as no doubt it will some day, we may expect to ride around the Yosemite on a train of trolley cars. And how rapidly it has all come about. It was just ten years ago that the president of this Association, at the Chicago meeting, with a foresight, which must have been born of intuition, ventured to predict that the lightning would some day be harnessed to the horse car. We laughed at his visionary prophecy, and dismissed it from our minds as a piece of optimistic nonsense. But the prophet of a decade ago is with us to-day, and can take revenge by saying "I told you so."

This is an assembly of practical men who have come together not to vie each with the other in making extravagant predictions, but rather to contribute each to a common fund the results of his observation and experience. The congestion of traffic in our business centres, the increasing throngs of passengers of the working class nights and mornings as the day of tenement houses gives way to the age of suburban cottages, the safeguards against accidents required by the exigencies of rapid transit, the labor question, the unjust and burdensome taxation of corporations, the ways and means of increasing traffic and reducing the cost of maintenance and operating expenses, give us plenty of things to talk about. The principal subjects for discussion cover a wide range of practical matter having an important bearing upon street railroading as a business conducted for profit rather than for philanthropy, and the reports of the special committees will be worthy of your closest attention and most careful consideration.

SECRETARY RICHARDSON then read his report showing 206 companies in full standing of membership, a gain of 22 over last year. The outlook was excellent. Milwaukee had been selected as the place for the next, twelfth, annual meeting.

The treasurer's report showed a balance of $1,524 on receipts of $7,574.

MR. D. S. LONGSTREET read a historical sketch, giving an account of the formation of the Association. He was thanked for it.

MR. G. W. BAUMHOFF then read a valuable report on A Model Electric Railway Roadbed and Underground Wiring.[1]

---

[1] Abstract of a report submitted to the American Street Railway Association, Cleveland, Ohio, Oct. 19-21.

[1] See page 396.

Convention then adjoined until evening, when a long discussion was had on the details of Mr. Baumhoff's paper, in which a number of members joined.

A resolution was adopted requesting the chair to appoint a committee of five to act in conjunction with the executive committee in deciding the feasibility of forming an industrial association. The object of the proposed Association is to pave the way to advanced ideas by having a stated place for exhibits of appliances and authorized agents to make experiments for the good of all. The gentlemen appointed on the committee were Messrs. H. C. Paine, Milwaukee; D. F. Longstreet, Denver; O. T. Crosby, Boston; W. M. Wharton, Jr., Philadelphia; H. A. Everett, Cleveland. The convention then adjoined until 10 o'clock Thursday.

The supply men also took up at a special meeting in the evening the question of a supply organization, Mr. J. E. Lockwood presiding. There was a powerful discussion, and a committee was appointed to report next evening. The project was abandoned, however, before the close of the convention.

THURSDAY MORNING SESSION.

The delegates reassembled at 11 o'clock for the morning session. In the absence of the president, Mr. Thomas H. McLean, general manager of one of the large New York companies, occupied the chair. A communication was read from President Holmes, stating that he had suddenly been called away from the city by a telegram announcing the illness of a member of his family. The committee on nominations was announced as follows: Messrs. Charles Cleminshaw, Troy, N. Y.; W. A. House, Baltimore, Md.; Albert Johnson, Cleveland; J. E. Rugg, Pittsburgh; G. W. Baumhoff, St. Louis, and V. Cronyn, London, Canada.

It was moved that the time for discussion of papers be limited to a half hour and that no member be allowed to hold the floor more than five minutes. The report of the committee on "A Perfect Overhead Construction," concerning which a paper had been prepared by Mr. George W. Baumhoff, of St. Louis, was ordered printed in the minutes without discussion. A paper on "Economy of Machine Shops for Electric Street Railways," [1] which was prepared by Mr. J. H. Bickford, of Salem, Mass., was presented to the convention. A discussion, in which many practical points were brought out, followed the reading of the paper.

Mr. **Wm. Richardson**, of Brooklyn, N. Y., introduced a resolution expressing the sympathy of the convention with President Holmes and the regret experienced on account of his departure.

A paper on "The Relative Cost of Operating Horse, Cable, and Electric Roads" [2] was read by Secretary Richardson. The report was prepared conjointly by Mr. W. M. Ramsey, superintendent of the Federal Street and Pleasant Valley Railway Company, of Pittsburgh, Mr. F. R. Greene, secretary of the Chicago Railway Company, and Mr. John Heins, superintendent of the Brooklyn City and Newtown Railroad Company. The ensuing discussion showed a great preponderance of feeling and experience in favor of electricity.

A report was presented showing that the exhibit at the World's Fair next year will be very fine.

A report from a special committee of the Massachusetts Street Railway Association, asking the convention to take action touching the question of grade crossings and legislation concerning them was presented by Mr. G. W. Mansfield, chairman of the committee. One of the recommendations was that an automatic signal system be put in operation, which system would indicate at one thousand feet distance the approach of trains on either the street or steam railway. The executive committee was allotted the duty of preparing a suitable report concerning the matter in question. After the noon adjournment the members of the convention were photographed on the steps of the Young Men's Christian Association Building.

AFTERNOON SESSION.

The afternoon session was opened at 4 o'clock by a paper embodying the report of the committee on Standards for Electric Street Railways, read by Mr. O. T. Crosby.[3] Associated with Mr. Crosby in the preparation of the report were Messrs. H. J. Bettis, of Atlanta, Ga.; Edward E. Higgins, of Cleveland; Charles W. Wason, of Cleveland, and Julius E. Rugg, of Pittsburgh, Pa.

Mr. **A. L. Johnson**, of Cleveland, reported for the nominating committee, the following selection of officers to serve during the coming year: President, Mr. D. F. Longstreet, of Denver, Col.; first vice-president, Dr. A. Everett, of Cleveland; second vice-president, Mr. Joel Hurt, of Atlanta, Ga.; third vice-president, secretary and treasurer, Mr. W. J. Richardson, of Brooklyn, N. Y.; executive committee, Messrs. J. G. Holmes, of Pittsburgh; J. D. Crimmins, of New York; T. J. Minary, of Louisville; J. R. Chapman, of Grand Rapids, and B. E. Charlton, of Hamilton, Ont. They were all elected.

Owing to the exhorbitant charges which the hotels of some of the former convention cities have inflicted upon the members of the Association, a resolution was introduced recommending that the by-laws be so amended as to give the executive committee the power of changing the place of any meeting 60 days previous to the meeting by notifying every member of the Association to that effect. The question was discussed at length, and the final result was the tabling of the resolution.

Messrs. Wharton and Eppley were appointed a committee to escort the newly elected president to the chair. Before taking his seat Mr. Longstreet made a short address thanking the association for the honor, and expressing his interest in the organization.

The secretary presented a report of the committee meeting with the special committee from the supply men concerning the formation of a supply men's union. It was voiced as the sentiment of the Street Railway Association that there was no need to either party that a separate organization should be formed by the supply men.

On motion it was ordered that the nomenclature recommended in the report of the committee be adopted as the standard to be used by the Association.

The business of the convention not having been completed at the afternoon session, adjournment was taken until 10 o'clock Friday.

FRIDAY MORNING.

On the opening of the morning session, the paper by Mr. A. J. Moxham on "Experiments on the Expansion of Continuous Rails" [1] was read by title. The same thing was done with the paper by Mr. J. T. Ostrom, entitled, "Is a Standard Rail Possible." [2]

A resolution was passed inviting foreign street railway men to the World's Fair.

Thanks were voted to the Short Company for its many courtesies.

The Convention adjourned to meet at Milwaukee, third Wednesday in October, 1892.

EXHIBITS.

In their exhibition this year, the General Electric Company have surpassed all the previous exhibitions made in the old days of the Edison and Thomson-Houston companies. They are now able to show what was best by the combined talent of the two former rivalries. The exhibition was in every way worthy of so large, energetic and prosperous a corporation, and has gone far to convince any still skeptical of the merits of their street railway system. The arrangement of their exhibition permitted an examination of their entire railway system without any exertion to locate the different devices. We were especially taken with their motor exhibit. It seems a late day to say anything further about the motors of the General Electric Company, but we were enabled to see them thoroughly this time and gain a knowledge of certain advantages which they possessed which we had not had an opportunity of previously examining. On a "Brill" truck, 2 W. P. 30 single reduction railway motors were mounted, showing their lightness, general compactness and ease of adaptation. The W. P. 50 motor, with the hollow field and field coil thrown back, allowed one to examine the interior parts and analyze the claim of the motor to the possession of fewer parts than any other railway motors. The S. R. F. 30 motor—a modification of the old F. 30—was arranged next to this, and is described in detail elsewhere in our pages. Next to this, we found the Standard S. R. G. railway motor, which is already too old a friend of the street railway men to need further description. An Edison No. 14 motor was mounted in the centre of the exhibition. This also we have previously described at length. We saw here an entirely new device—a gear press for applying and removing gear wheel from motors. We were struck by the simplicity of this device, and predict its wide adoption by the users of motors of what description soever. The series parallel controller next claimed attention. From this, any objectionable features which were found in those first made had been eliminated, and the series parallel controller as it now stands will prove a great economic element in calculations of street railway managers. One of the particular features of the exhibition were the overhead parts described before. They were arranged on a long, sloping board which showed them off to considerable advantage. In order to render them still more conspicuous, they had been carefully plated and polished so that this board shone like a jeweler's show case and quite as attractively. By the side of all this glory was shown "ye ancient appliances" of only six years ago. Surely, no greater proof of the rapid development of the electric street railway could be given than this—the contrast between these old and obsolete appliances and the practical devices of the present day.

Another striking exhibition which they had was their station switchboard equipped with automatic circuit breaker and current indicator of the latest and most improved type. This stood by the side of a board on which were mounted several of the Thomson wattmeters working, in order to show their method of operation and record. Two special car fixtures completed the exhibit.

---

1. See page 403. 2. See page 400. 3. See page 398.

1. See page 402. 2. See page 404.

Small electric lamps outlined the name of the company in different positions around the exhibit; and, in the centre was an American eagle perched on the top of a shield formed of small incandescent lamps of the patriotic colors.

The General Electric Company ran two magnificent cars over the East Cleveland Company's lines—one, a special vestibule car upholstered in deep brown plush, and furnished with easy chairs. This was mounted upon a single truck equipped with two W. P. 30 motors. The other car was a giant, 40 feet long with a double truck, each equipped with a W. P. 50 motor. The floor of this was removable, to enable the operation of the apparatus to be seen. Recording instruments showed how much energy was required to operate the cars. It is such cars as these that mark an epoch in the street railway era.

The headquarters of the company at the "Hollenden Hotel" were most tastefully decorated with shrubs, ferns, plants and flowers, and hung with photographs setting forth the exploits of the General Electric Company. Mr. W. J. Clark, the general agent of the Railway Department, in whose hands the entire management of the General Electric Company's exhibit was placed, acted as host, and his geniailty and cordial greeting of all the visitors won for him the good-will of every one at the convention. Mr. Clark was ably seconded in his efforts by Mr. Elmer P. Morris, of the Railway Supply Department; Mr. G. K. Wheeler, assistant manager of the Chicago Railway Department; Mr. F. J. Clark, manager at Washington; Mr. H. H. Harrison; Mr. C. S. Rusling: Mr. I. Silverman; Mr. W. A. Stern, and a thoroughly competent staff of General Electric Company's men.

The General Electric officials on the ground were: O. T. Crosby, W. J. Clark, G. K. Wheeler, Paul T. Brady, F. H. Clarke, C. S. Rusling, W. H. Knight, E. W. Rice, Theo. Stebbins, Arthur W. Jones, A. A. Glazier, Caryl D. Haskins, John McGhie, Geo. W. Mansfield, E. G. Waters, W. A. Stern, H. H. Harrison, C. E. Hart, A. H. Lewis, T. H. Fearey, R. J. Randolph, R. H. Strieby, C. T. Hamilton, F. E. Jackson, F. E. Allen, S. P. Wells, C. R. Stearn, Percy Hodges, T. F. Mullaney, M. H. Hamilton, J. A. Kimball, H. S. Elliott, —— Ewing, F. H. Bostwick, B. M. Barr, F. Houghton, G. H. Stout, E. P. Sharp, W. B. Potter, G. H. Alton, —— Woolsey, R. E. Hood, Geo. M. Haskell, F. J. Reynolds.

The Technical Press was well represented. *The Street Railway Journal* had handsome headquarters, with electrical effects, and distributed a most beautiful and interesting souvenir of Cleveland, describing the electrical and other railway industries of the cities, and giving views of its most beautiful buildings and resorts. The souvenir is certainly something to be proud of. The *Street Railway Gazette* distinguished itself by publishing its regular issue in Cleveland, so as to dodge the Columbus celebrations in Chicago, and thus avoid delay. The *Street Railway News* made a hit by issuing a neat daily bulletin.

The Detroit Electrical Works were ably represented by Jos. E. Lockwood, secretary, and L. E. Myers, who holds down Chicago with the help of the Monadnock Building. A graceful compliment was paid Mr. Lockwood in placing him in the chair at the important meeting of the supply men on Wednesday evening, when it was proposed to organize an association. The proceedings were of the most picturesque character, and there was plenty of chance to allow unparliamentary scenes, but Mr. Lockwood ran things in an easy, masterful way, and pleased everybody.

The Edison Manufacturing Company had a mighty name to conjure with, and their new Edison electrostatic voltmeter, shown in Army and Navy Hall, by Mr. E. M. Smiles, attracted very general attention. It has a very considerable advantage for station and power house work in the fact that it can be placed in close proximity to the generators and is wholly undisturbed. The mechanism is very simple and easy of adjustment. The scale is very legible and can be made out several feet away.

J. H. Bunnell & Co. were represented by Messrs. C. McLaughlin and J. J. Ghegan, who gave evidence of a keen appreciation of all the latest advances in the art. Mr. McLaughlin is a director of the Paterson, N. J., electric road, and being also a large electrical manufacturer, he is in a peculiarly favorable position to know the good qualities of new railway methods and apparatus. After taking in the convention, this Bunnell contingent moved on Chicago.

The Interior Conduit and Insulation Company were represented by C. A. Benton, who had many interviews on the subject of putting in their conduit for railway feeders. Mr. Benton also found a great many men who had heard of the Sprague electric elevator, for which he is the special agent, and who knowing Mr. Sprague's magnificent record in the railway field, are ready to accept his elevator as no less distinct an advance.

Kuehnle Trolley Wheel. A peculiar and apparently desirable improvement in trolley wheel construction was shown by Mr. John Kuehnle, of Detroit. The hub is composed of roller bearings, one roller being filled with powdered graphite feeding automatically on the axle. Great advantages are claimed for this wheel, and it is at least an ingenious device.

Mr. Wm. Taylor, of Taylor, Goodhue & Ames, Chicago, made his first appearance at a convention as president of this newly organized railway specialty company. He reports having secured the Western agency of the Philadelphia trolley, Wagner motors for street railway circuits, the Columbia incandescent lamp, and the Nutting arc lamp, both of which are for use on street railway circuits.

A Three-Ply Leather Belt, 116 feet long and 6 feet wide, was one of the first exhibits that met the eye upon entering the hall. It was made by the Chas. A. Schiern Company, of New York, for the Brooklyn City Railway, and weighs 2,200 lbs. Chas. A. Schieren, Jr., and Mr. E. P. Atkinson looked well to the interests of the company. Their perforated electric belts were also exhibited.

The Cleveland Electric Manufacturing Company were represented by Mr. R. B. Williams. They are agents for the Indiana Rubber Company and of course there were some reels of "Paranite" visible. They are also agents for the Standard Electric Time Company and manufacturers of the American watchman's time detector.

Electric car heaters, also office and dwelling heaters, were shown and some excellent results given by the Dewey Electric Heating Company. Mr. E. B. Wyman, general manager, and Mr. M. W. Dewey entertained the curious. These heaters were recently described in The Electrical Engineer.

Mr. C. O. Mailloux, the electrical engineer, was at the convention, and answered many questions as to his automatic load equalizer. It may be truly said that the whole country watches with interest his results with storage batteries on the Metropolitan Road in Washington.

J. A. Ferguson showed the Shultz Belting Company's patent sable rawhide belt and the patent leather pulley cover manufactured by this company. They have just completed a 132-foot 54-inch belt for the Union Depot Electric Railway Company, of St. Louis.

Daniel Coolidge, Johnstown; Major H. C. Evans, New York; W. E. Boughton, Philadelphia; W. B. Kingston, Atlanta, Ga., and O. C. Evans, Cincinnati. This list of names means the Johnson Company, of Johnstown, Pa. No further mention necessary.

There is only one Supply Manufacturing Company. They are at 100 Wood St., Pittsburgh, and their commutators are the only ones made of Eureka tempered copper. Moral. R. R. Hammond lost no chance to explain all this to those interested.

The Electrical Engineer was represented by Messrs. F. R. Colvin, T. C. Martin, L. W. Collins, and Mr. Willson, its Cleveland correspondent. It had two large rooms for headquarters, and distributed several hundred copies of its current issue.

C. H. Smith, of Troy, N. Y., showed an ingenious and simple device which should at least appeal to the employees on electric cars; his trolley finder should be a *finder* of great favor. His changeable signal box was also interesting.

Mr. J. D. Elwell, Mr. H. S. Carghill and Mr. S. Russell, Jr., had an interesting exhibit of their Duplex street railway track. This was a most interesting exhibit to all directly interested in street railway work.

J. W. Godfrey.—Well, that means New York Insulated Wire every time. The interests of the New York Insulated Wire Company are always well taken care of in the hands of their general manager.

A most desirable feature pursued by the General Electric Company in presenting their souvenir book was the printing in gold of the name of the recipient on the handsome morocco cover.

Frank A. Magee had an interesting exhibit of the E. S. Greeley Company's railway specialties, test instruments, etc., notable among which was the celebrated Duggan trolley bracket.

Mr. F. B. Rae.—A street railway convention without the familiar form of F. B. Rae would be a strange thing and of course he was at Cleveland. His many friends were glad to see him.

"A. B. C." had their interests at the convention entrusted to Mr. H. G. Issertel, manager of the railway department. It is needless to say they were well looked after.

John A. Roebling's Sons Company had Mr. H. L. Shippy and Capt. Sparling as representatives.

The Johnson Electric Co., manufacturers of electric railway supplies, showed a fine line of samples in Army and Navy Hall. J. J. Coleman was there in the interest of the company.

Louis McCarthy, treasurer and general manager of the W. T. C. Macallen Company, of Boston, showed their solid mica insulators.

Mr. Hollis French was there in the interests of his company, the Massachusetts Electrical Engineering Company.

The Short Electric Railway Co. did the honors for Cleveland in a manner beyond all reproach, and were most ably represented by Messrs. Short, Potter, Hazleton, Curtiss, Wessels, Scheffler and others of the staff, aided by Messrs. Phipps, of the Brush Works, and Professor Roberts, of the Swan Lamp Mfg. Co. At the Hollenden House, beautifully decorated parlors were occupied on the first floor, where the tasteful literature of the company was freely dispensed, with souvenirs of all kinds for the delegates and their wives. There were also shown lighted Swan lamps embedded in ice and other egg lamps nested under graceful swans. On Wednesday afternoon, on a train of Short cars run down to the hotel over a track built for the occasion, the convention went en masse to the factory, where they were graciously received by Prof. Short, Mr. Potter and Mr. Hazleton, and not only entertained with a sumptuous luncheon but escorted all over the works so that they could see for themselves the new Short gearless in process of construction. In the Swan lamp works, Prof. Roberts showed the visitors how lamps are made, and a pretty lamp-vase souvenir, made out of a lamp bulb was given to the ladies. The masculine contingent received dainty leather pocketbooks containing a variety of most valuable electric railway data. Many trips were taken on the gearless cars, under the charge of Mr. Curtiss and Mr. Wills, and all the electric railway plants were visited, a warm reception being given at all of them.

The Short Company also had a fine exhibit on the stage of Army and Navy Hall, of their motors, generators, and detail apparatus under the care of Mr. C. F. Uebelacker and a large corps of assistants.

The Ford-Washburn Storelectro Co., of Cleveland, made a most interesting exhibit of their storage battery in Army and Navy Hall, under the charge of Mr. Washburn. The battery was shown complete, and in parts, charged and uncharged. The storage battery car was also actively on exhibition and was freely utilized in making trips around the city, where it attracted the utmost attention from the delegates and the public. The car was run with the instruments on, so that everybody could study the consumption of current. It is greatly to be regretted that the storage car was in a small minority at Cleveland, but if it goes on making such records as this car does, it will soon occupy a much larger place. The Ford-Washburn people have a good thing, and the convention at Cleveland must bring their battery to the front.

Among the notable features of the Hirt six-wheel radial truck exhibited at Cleveland last week, were the wrought iron castings used on these trucks for clamps, jaws, and other parts where great strength and toughness are necessary. They were made by the Wrought Iron Casting Co., of South Boston, Mass., who are doing a large business in this line of work and also in dynamo and motor castings.

Mr. Ludwig Gutmann made an exhibit at the Brush electric light station, through the courtesy of its manager, Mr. Sam. C. D. Johns, of his new alternating current motor in fan sizes. The motor is of simple and inexpensive construction, and takes very little current, runs cold and quietly, and is very pretty to look at. It is destined, in our opinion, to a very wide use.

Mr. W. E. Irish, a well-known Cleveland electrician, was in attendance, and took many friends to his laboratory, where they saw his new sectional conduit railway system and his very simple new arc lamps for alternating and direct current.

The Genett Air Brake was exhibited by Mr. David Reid, the Chicago agent of the company. This novelty is a conspicuous bidder for popularity, and a most desirable one too. Simplicity and a positive brake are its features.

H. P. Barr, secretary and treasurer, exhibited for the first time the new Sperry electric railway system. Mr. Elmer A. Sperry, the inventor, was also on the ground. Theirs was a particularly interesting exhibit.

Capt. Willard Candee, of the Okonite, and Mr. H. D. Stanley, who has but recently connected himself with this company, were there. Okonite interests could not possibly suffer in the hands of these gentlemen.

Billings & Spencer. Arrangements were so made that the Connecticut contingent grouped their exhibit. F. G. Billings showed a sample board of their commutator bars and drop forgings.

Mr. Reimond, president of the Mosher Arc Lamp Company, spent a day or two at the convention. This company have recently received some very flattering orders for their arc lamp.

The Ahearn Electric Heater was one of the exhibits of the Railway Equipment Company. Mr. Soper and Mr. Dewar, of Ottawa, were in attendance.

J. G. White, the electric railway contractor, New York, interested many of his friends in reports of new construction work in hand.

The Westinghouse Electric and Mfg. Co. made an extremely effective exhibit, not of the brass band order but rather that of the still small voice kind. Their headquarters were in a large room off the main entrance to the Hollenden, and were plentifully supplied with pictures, pamphlets, photographs, etc., all relating to Westinghouse apparatus. The company was represented by the following gentlemen:

Lemuel Bannister, vice-president and general manager; W. C. Clark, general agent, assistant treasurer; Albert Schmid, general superintendent; H. McL. Harding; W. F. Zimmerman, assistant general manager; A. J. Wurts, electrical engineer; J. A. Rutherford; T. W. F. Gray; R. S Brown; A. L. McCarthy; E. L. Ludwig; G. Pantaleoni; A. S. Stewart; E. R. Bragg; H. Franz; T. N. Waterman; Antoni Gonet; W. J. Longmore; E. H. Heinrichs.

The exhibit in Army and Navy Hall, included two 25 h. p. railway motors on truck, one 25 h. p. in separate parts; a switchboard with voltmeter, ammeters, lightning arresters, circuit breakers, switches, etc.; a tank lightning arrester; non-arcing arresters for alternating circuit; street car fuse blocks; multiple series controlling devices, etc. There was also shown a fine group of Westinghouse cars on Woodland avenue, which were freely used, and which elicited frequent, well-deserved encomiums from veteran electric railway men, on account of the simplicity, high finish, light consumption of current, etc.

The Washburn & Moen Co. showed a most complete line of samples of their insulated wire, particularly a section of their 2,500,000 circular mils insulated cable, this being the largest cable ever insulated. They also showed a sample of a 500,000 circular mils cable, of which 35 miles have been sold to the new Brooklyn Electric Railway Co. The famous Salamander wire test was very interesting. This test was made by Mr. Snedeker, the patentee. It thoroughly proved that the insulation is perfectly fireproof. To make this test it was necessary to put another interesting exhibitor's goods to a most severe test, and that was the repeated short-circuiting of a Ford-Washburn Storelectro Company battery. This was done repeatedly without doing the least harm.

A special railway lamp was shown by Mr. Jackson, from the Edison lamp works of the General Company. It is intended to be run in groups of five, at 16 and 30 c. p. The filament is thick, but when uncoiled would be longer than the ordinary one. The glass envelope is also made shorter, having practically no neck. The lamp as now made is for interior use but it is also to be made waterproof. It fits all the old Edison, and Thomson-Houston railway sockets.

The Charles Scott Spring Co., of Philadelphia, made a most interesting exhibit of their spiral and elliptic springs for trolley and motor use. Their springs are made for all standard trucks. The company were well represented by Mr. Chas. Scott, Jr., and Mr. H. C. Johnston. The springs of this well-known company are in almost universal use and are giving excellent results. A very handsome souvenir was distributed.

Jewell Belting.—A display of Jewell belting was well looked after by Mr. C. E. Newton, secretary; Mr. G. W. Bancroft, general sales agent, and Mr. C. L. Tolles. They showed, among other things, a very fine double 48-inch generator belt, made for the General Electric Co., New York. A handsome souvenir was eagerly sought.

The Railway Equipment Co. was represented by Mr. W. R. Mason, general manager; W. L. Adams, C. S. Bowe, J. F. Macartney. They had parlor headquarters in the Hollenden, as well as an interesting exhibit in the hall.

Mr. W. F. D. Crane represented the H. W. Johns Co. and showed some interesting samples of molded mica insulators, storage battery plate separators, switch-bases, cut-out blocks, and sockets in their special product, *black mica.*

A convention without P. C. Ackerman would be lacking a great deal. This, however, does not occur, as he is always there, and the American Electrical Works interests are in good hands.

Mr. J. B. Allan, general agent of the Edward P. Allis Co., of Milwaukee, was on the ground and did the proper thing for the Reynolds-Corliss engine.

The Carpenter Enamel Rheostat interests were personally taken care of by Mr. C. E. Carpenter. They had an interesting exhibit of their products.

"Ajax" Van Nuis was there with his switches and Fulmen lightning arresters. The arresters made an interesting souvenir.

The Field Engineering Company, New York, was represented by its popular president, Mr. C. J. Field, M. E.

J. A. Hanna and D. B. Dean were kept busy telling the good points in the well-known McGuire truck.

Messrs. Baird and Newton, of the Eddy Motor Company, were on the ground.

The Eureka Tempered Copper Co.'s exhibit was tastefully displayed on the second floor of the Army and Navy Hall, and was in charge of Mr. Jno. R. Coffman and Mr. J. R. Phillips. Next to this exhibit was that of the Supply Manufacturing Co., an item regarding which appears elsewhere. As the very handsome and well-finished commutators of this company are all made from the Eureka Tempered Copper Company's product, the combined display of tempered copper was well worth seeing, and naturally attracted much attention on the part of the delegates and visitors. Some idea of the scope and magnitude of the E. T. C. Co.'s business may be gathered from the fact that they are now turning out over 5,000 different patterns of commutator bars and segments. Five hundred of these are turned out for the General Electric Company and Westinghouse Electric and Mfg. Co. A few attempts have been made by other parties to manufacture tempered copper by the use of an alloy; as an evidence that the E.T.C. Co. have to-day the only absolutely pure tempered copper on the market, they expressed their willingness at the convention to forfeit $1,000 in cash could any pure tempered copper other than their own be produced or exhibited. At the close of the convention the offer still remained open without a taker. This company is now ready to move into the new extension to the works. The capacity of the company has already been several times increased, each extension being larger than its predecessor.

Mr. George H. Bryant showed the Bryant metal saw, manufactured by the Q. & C. Company, of Chicago. This is a most interesting device, and would seem an almost indispensable acquisition to street railway track laying where so much cutting of rails is necessary. It is perfectly automatic, easily fastened to the rail it is cutting, and will cut any angle. Many interested ones watched its easy meanderings through the hardest of chilled steel rails.

Mr. F. B. Brownell, of the Brownell Car Company, of St. Louis, had with him one of their remarkable "Accelerator" cars which have a most extraordinary capacity for unloading quickly by means of their double doorways and large platforms. It certainly looks as though they solved the problem of picking up large numbers of passengers quickly and putting them down with equal rapidity.

The Goodrich Hard Rubber Co., of Akron, Ohio, were represented by Mr. C. B. Raymond. Even now they have a large demand for hard rubber magnet heads, keys, knobs, window tubes, etc., but they know there is a right down good time coming with the approach of storage battery traction, when their hard rubber specialties will be more than ever in demand.

Alex. Lewis, so well known throughout the West from his connection at Cincinnati and Chicago with the Thomson-Houston and Edison General Co., and now holding a prominent position in the New York office of the Railway Department of the General Electric Co., received a right royal reception from a host of friends.

The Fulton Foundry Co., of Cleveland, were represented by Mr. W. E. Haycox, manager of the Street Railway Department, and Mr. C. J. Langdon. They showed a very fine motor and trailer truck, also a novel brake shoe with interchangeable slippers and the Lyons patent brush holder for railway motors.

The Partridge Carbon Co., of Sandusky, Ohio, displayed a full line of dynamo, motor and generator brushes, for the excellence of which goods this company is celebrated. Messrs. Partridge and Speer were both in attendance.

Gilbert M. Smith, Chicago, did good work at the convention for the Aluminium Brass and Bronze Co. Their souvenir was a paper weight (featherweight) of aluminum. Some one should stick a pin in this if it is a joke.

H. M. Loud & Sons Lumber Co., of Oscoda, Mich., showed octagonal poles for electric railways, and were glad to find their customers "loud," also, in praise of these trim pieces of construction material.

Mr. A. H. Englund, secretary and manager of the International Register Co., of Chicago, showed very handsome samples of their cash register.

The Western Electric Co., New York and Chicago, were on the ground with a miscellaneous line of supplies.

Mr. C. E. Bibber showed the Lyons break for the Consolidated Electric and Manufacturing Co., of Boston,

A special railway fuse, made by the Shawmut Fuse Wire Co. was shown by Mr. S. B. Condit.

Mr. Miller, of Pierce & Miller, sounded the praises especially of the McIntosh & Seymour engines..

E. Peckham showed one of his celebrated cantilever trucks, and his cushioned motor wheels.

W. H. Peck & Co., of Cleveland, showed samples of railway supplies and rubber goods.

Mr. J. L. Barclay attended the convention all through.

The J. G. Brill Co. have their cars and trucks so largely in use, that an exhibit was hardly needed, especially as the Woodland Avenue line in Cleveland has Brill cars for its Westinghouse system. But the company did not neglect the regular exhibition, in Army and Navy Hall, and showed there several handsome models of its special and well-known trucks. At the same place, the General Electric Company also showed one of the new Brill trucks with W. P. motor equipments. There were on the ground Messrs. J. G. Brill, Jr., Payson K. Andrews, F. C. Randall, W. H. Hulings, and Curwin.

New Process Raw Hide Co.—An interesting exhibit indeed was that of the New Process Raw Hide Co. A. C. Vosburg, secretary; T.W. Meacham, president, and J. C. Kenyon, treasurer, were in charge. They showed a number of samples of their rawhide gears and pinions. The special part of the exhibit was a motor pinion taken from a Sprague No. 6 motor, having a record of 22,000 miles on the West Bay City electric road. It is still in excellent condition and fit for as many miles more.

R. B. Corey, manager of the Electric Construction and Supply Company, was at the convention. It is needless to say that the famous "Ward Lamp" was the text for most of the interesting conversations which we found him engaged in. These lamps are in such general use in Cleveland that it was scarcely necessary to have a sample on exhibition.

The Standard Paint Company were admirably represented by Mr. P. H. Hover, from Chicago. The company have a large factory in Cleveland and are just opening another big one at Bound Brook. Their P. and B. compound is known as an indispensable auxiliary to the business.

Simplex.—It is unnecessary to say that the interests of the Simplex Electrical Company, of Boston, were well taken care of in the hands of General Manager J. H. Mason and Assistant Manager Major D. T. Everts. No opportunities were lost by either gentleman to say a good word for Simplex.

Mr. J. A. Tackaberry and Mr. D. W. Pugh lost no opportunity to say a good word for the John Stephenson cars. Their task was an easy one as the mere mention of the name John Stephenson is a spell and charm. They are again presenting a handsome memorandum book.

R. D. Nuttall Company showed a full line of electric railway supplies and specialties, including their raw-hide motor pinions. Messrs. R. D. Nuttall, W. C. Groetzinger, C. J. Mayer and P. H. Corey, Chicago, represented this enterprising firm.

Garton Lightning Arrester.—An ingenious device was the Garton lightning arrester. It was shown by Mr. Garton, of the Garton-Daniels Electric Company, of Keokuk, Iowa. Absolute protection is guaranteed to all railway apparatus.

The Graves Arc Lamp.—It was bright as day in the pavilion from dark until sunrise, as fifty Graves arc lamps were distributed about and above the different exhibits. They did themselves and their manufacturers credit.

The Babcock & Wilcox Company, New York, were represented by Messrs. J. A. Taft, P. B. Hayette, S. H. Scovel and W. C. Temple. They distributed their beautiful work on "Steam."

The Robinson Radial Truck Co. took excellent care of the delegates by placing car No. 250 at their disposal, and by issuing a complete time table for its trips morning and afternoon.

Secretary Geo. C. Shepard, of the Brightman Stoker Company, was kept busy explaining the many good points of their mechanical stoker to an interested audience.

G. M. Angier did good work for the Mather Co. Mr. Angier has a host of acquaintances in the business. His many Western friends were glad to renew old times.

G. H. Herndon said many good things regarding the Brightman mehanical stoker. This was a most interesting exhibit in operation. It must be a money saver.

Lamokin Car Works, of Chester, Pa., were ably represented by Superintendent Henry Cochrane and Mr. G. E. Pratt. They had one of their new cars running.

The Walworth Manufacturing Company, of Boston, were on hand and made a fine showing of their universally-known iron poles.

The Griffin Car Wheel Company, of Chicago, were on the ground and showed several of their particular line of wheels.

A small section (working) of the Combination car of the Combination Car Company, of Boston, was of great interest to many of the visitors.

The Safety Brake Shoe and Construction Company, of Boston, showed samples of their ingenious brake shoe.

O. W. Mysenburg & Co., Chicago, were represented by the genial W. A. Littlefield.

The Rochester Eureka Wood Filler Co. are placing on the market a most desirable wood filler for use in car building. It works perfectly on oak, ash, walnut, birch, cherry or mahogany; in fact, on any wood at present used by street car builders. It is the only liquid filler that can be used on oak or ash with guaranteed success. It can be used over water or vegetable stains to bring out the color. This company also manufacture a substitute for shellac that should be interesting to car builders. It is used extensively as a filler, and it can be sandpapered easily inside of one hour after it is put on. This particular article can be supplied at a much less cost than any similar article at present on the market. Being manufacturers, this company have on hand at all times a large stock of liquid and paste fillers, car varnishes of excellent quality, and, in fact, all kinds of finishing material. Persons needing anything in this line should at least write the company for samples and prices. Their address is D. R. McKissick, secretary and treasurer, Rochester Eureka Wood Filler Co., Rochester, N. Y.

Mr. R. S. Bishop, of the American District Steam Company, of Lockport, was at the convention embracing the excellent opportunity to place before the street railway people the theory of, and the system his company has for, the sale of exhaust steam for heating stores, dwellings, warehouses, etc. Mr. Bishop not only reports a number of new plants sold to electric light and power stations, but, reports that the exhaust steam plant sold to the Springfield, Ill., electric light station has proven so satisfactory and such a profitable investment to the residents that a considerable extension of the system has been undertaken; this it is expected will be completed by the end of the present month.

Johnston Disconnector.—A decided improvement has been made in the Johnston automatic safety disconnector for railway circuits. This improved device in its original form has been illustrated and described in The Electrical Engineer. Mr. F. B. Jacobs, secretary and treasurer of the company, and Mr. W. A. Cullen, superintendent of construction, were kept busy explaining how it was possible to take an apparently live wire in their hands without the least danger. Their device is being installed on the lines of the electric road at Paterson, N. J., and some interesting reports may be expected.

C. S. Jones, vice-president, H. E. Brown, secretary and treasurer, and F. B. Perkins, electrician, were at the convention in the interests of the Toledo Electric Heating Company. This is the maiden exhibit of this heater, and it evoked considerable interest. Several points as to economy, simplicity and especially durability for street car work are claimed. The company will make arrangements with parties desiring to handle their heaters in the West and in New York.

Mr. H. Ward Leonard was on the ground in the interests of H. Ward Leonard & Co., who are to-day constructing one of the most interesting electric roads in the country; that which Mr. T. C. Frenyear, who was also present, has organized between Johnstown, Fonda and Gloversville, in this State. It will be a passenger and freight road and will handle a heavy goods traffic. Mr. Leonard also assisted Mr. Carpenter in explaining the merits of the Carpenter car rheostats.

The Walker Manufacturing Co. had a large exhibit and a host of representatives in attendance. A pleasing event of Friday morning was a carriage ride to their extensive works in West Cleveland. About 300 delegates availed themselves of this opportunity to visit these wonderful works, created by American enterprise and the growth of the cable industry.

Mr. Lodge and Mr. Shepley, of the Lodge & Shepley Machine Tool Company, of Cincinnati, were both in attendance and showed a most novel motor gear lathe, which bores, turns and squares a motor gear all at the same time. Sales of this machine were made to R. D. Nuttall (1), Johnson Electric Co. (2), West End Street Railway Co. (1).

Mr. Walter C. Kerr was present in the interests of Westinghouse, Church, Kerr & Co., who have been putting in some very fine electric railway plants lately, from some of which, such as those at Biddeford, Me., and New Haven, Conn., an extraordinarily high efficiency has been obtained.

Mr. M. M. Wood and Mr. C. K. King were at the convention looking after the welfare of the Electrical Supply Co. They showed a line of specialties for overhead construction and of course did considerable talking on the merits of the Carpenter Electric Street Car Heater.

Wm. Wharton, Jr., & Co., of Philadelphia, were represented by Mr. W. Wharton, Jr., president; Mr. F. P. Home, second vice-president; Mr. Robert McCloy; Mr. A. W. Slee, Western sales agent, St. Louis; Mr. J. C. Robinson, New England agent.

Mr. H. L. Lufkin was in the city during the convention, attending to other important business for the C. & C. Electric Motor Co., but not neglecting his opportunities in the street railway field.

Sargent & Lundy, Western agents of the McIntosh & Seymour engines, and power plant contractors, had their interests in good hands. Mr. A. C. Harrington represented them.

Col. J. H. Shay, better known to electrical people as the "electrician" of the Munson Belting company, renewed many an acquaintance. The colonel rarely misses a convention.

The Van Dorn Street Car Coupler was a little device that attracted a great deal of attention. It is a very simple automatic coupler, now in use in Milwaukee and Fort Wayne.

The Cleveland Electric Manufacturing Company had an exhibit in the hall. Mr. F. J. A. Keller and Superintendent C. A. Dainz were on the ground most of the time.

The Duncan Trolley was explained to visitors by Mr. A. P. Manning; special points in this trolley are a large compressed spring swivel base and an automatic oil feed.

Mr. G. Herbert Condict, of Philadelphia, talked so hopefully of storage battery traction that it is believed he must have his eye on some important project.

W. Bingham was represented by Mr. C. E. M. Young, and showed an interesting line of street railway headlights, etc., and a remarkable hydraulic motor lift.

Without doubt one of the busiest men at the convention was Elmer P. Morris. The railway exhibits of the General Electric Co. were in excellent hands.

The Bradley Electric Railway Conduit Company showed a full size section of their system, Mr. Bradley explaining the desirable features.

L. H. Elliott, secretary, and A. J. Wright, president of the Reliance Gauge Co., showed a number of their guages and water columns.

Mr. W. A. Hathaway, of the American Electrical Works, made a flying trip from Boston to Cleveland to attend the convention.

E. Packer and F. W. Russell, of the Rochester car wheel works, were also there. They had a most interesting and complete exhibit.

Mr. John Taylor, of the Taylor Truck Company, of Troy, N. Y., showed a very handsome car truck manufactured by his company.

The Celebrated Chapman Valve was there on exhibition; the interests of the company were taken care of by Mr. E. L. Ross.

H. T. Paiste had his new self-oiling trolley wheel with adjustable contact with him to interest his many friends.

The "Nonesuch" Fibre Company, of Wilmington, Del., had Mr. W. L. G. Thomas at the convention in their interests.

E. Webster, of the Stilwell & Bierce Manufacturing Company, was at the Hollenden during convention days.

The Dayton Mfg. Co., of Dayton, O., was represented at the convention by Mr. P. Leidinger and Mr. Jos. Leidinger.

Hill Clutches hardly need mention, because S. S. Leonard told every person at the convention about them.

A Novel Rail Joint Tightener was shown by Mr. C. W. Pope, of the J. L. Pope Company.

The Perkins Lamp Company had Mr. C. J. Hill on the ground, looking after their interests.

F. M. Laughlin and H. E. Webb were there and talked Solar carbon to good advantage.

Warren Webster & Co., of Philadelphia, were represented by Mr. Wm. M. M. Candless.

Messrs. Pepper & Register, of Philadelphia, were represented by Mr. A. L. Register.

C. S. Knowles, of Boston, was represented at the convention by Mr. J. H. Parker.

The Sterling Boiler Co., of Chicago, was represented by Mr. F. E. Bruce.

Mr. Edw. P. Sharp represented the American Mica Company of Boston.

J. S. Pugh said many good things about the Baltimore car wheels.

The Annual Banquet was given on Thursday evening at the Hollenden, and was presided over by Mr. McLean, first vice-president. Among the speakers were: Mr. D. F. Longstreet, of Denver, the new president; Tom L. Johnson, and Wm. J. Richardson, of Brooklyn, the Nestor of the association, who contributed some most interesting memories of Cleveland, 58 years ago.

The Duplex Street Railway Track Company gave a récherché dinner on Wednesday, at the Stillman House, to John G. Holmes, president of the American Street Railway Association, Mr. H. H. Littell, founder and first president of the American Street Railway Association, and Mr. Henry Watson, ex-president of the American Street Railway Association. The Duplex Company was represented by Mr. John D. Elwell, Mr. H. L. Cargill and Mr. S. R. Russell, Jr. Other guests were John N. Beckley, president of the New York Street Railway Association; Mr. Charles Cleminshaw, Judge Kent, of Troy; M. H. Littell, L. Perrine, T. H. McLean, secretary of the Sixth Avenue Railway Company, New York; H. McL. Harding, O. T. Crosby and Mr. J. G. White, of New York. The distinction of the guests, and the taste with which the dinner was served in every respect, made the affair one of the leading events of the convention. The Duplex track is a well-known improvement now, and is in such strong and respectable hands that it has become a leading bidder for patronage in the rail department of the industry.

A Luncheon to the Ladies.—The wives of the delegates and other ladies brought to the city by the convention were the guests of Mrs. S. H. Short, on Thursday afternoon. A special excursion was enjoyed in the elegant private Short cars, which were placed at the disposal of the visitors. The route was out Euclid avenue to the Garfield Memorial, the return trip being made by way of Cedar avenue. The objective point of the return trip, however, was the Union Club, where a bountiful luncheon was given by Mrs. Short. The table was tastefully decorated with flowers, yellow being the prevailing shade. The affair was a most enjoyable one, adding not a little to the pleasure of the day. The guests numbered twenty-eight.

SOCIETY AND CLUB NOTES.

THE NEW YORK ELECTRICAL SOCIETY.

At the meeting of the Society, held at Columbia College on October 19, Prof. F. B. Crocker made a very interesting address entitled "What Europe is doing in Electricity." In order best to convey to his hearers the nature of the practice abroad, Prof. Crocker pointed out the differences between foreign practice and our own, and the reasons which dictated such differentiation.

Beginning on the subject of scientific instruments, Prof. Crocker thought that we were able to produce quite as good instruments as those made abroad, and named several American manufacturers, who, he considered, were well able to compete with foreign makers. Except, perhaps, in special apparatus, or in such involving much hand work, in which, of course, they excelled us abroad, we were abreast of Europe.

The field of electric lighting, Prof. Crocker thought, presented the greatest differences in practice. Their work there was striking on account of the large scale and substantial character in which it is carried out, the employment of large units, especially on the continent of Europe, being the general practice. It was apparent everywhere that no expense was spared to make installations perfect, although Prof. Crocker thought that foreigners went a trifle too far in money spent merely for ornamental effects in their stations. While, on the continent of Europe large units involving direct connected slow-speed engines are employed most generally, the practice in England tended largely towards the employment of engines running at between three and four hundred revolutions per minute. Both these methods were distinct from ours, as it exists at the present day, in which belt connection is largely predominant.

Prof. Crocker also dwelt at length upon the employment of storage batteries in the central station, which he considered a necessary evil, and which could only be applied with any degree of economy to stations having a light day load. Even then, Prof. Crocker thought, a small engine kept in operation during the light load would prove more economical than an installation of batteries, which were expensive in themselves, and required large space for their handling. Throughout his recent tour abroad Prof. Crocker met with not a single case in which the battery was used to assist the engine during the heavy load period. The success obtained with storage batteries abroad was undoubtedly due to their solid construction, in contradistinction to our thin and flexible battery plates. Prof. Crocker, contrary to his expectations, found the fixtures and fittings abroad very substantial and neat.

Electric power, as embodied in stationary motors, is still a thing of the future abroad. While we have from fifty to one hundred thousand motors in America, Europe all told did not have more than a thousand in operation. The transmission of water power, however, in Switzerland was quite advanced, and in that respect probably exceeded our own. The plants are, as a rule, very successful. Contrary to an opinion which seems to prevail among many here, there are comparatively few three-phase systems of power transmission in operation.

European electric railways are still few, and as a rule copied from our own practice, and we have nothing to learn from abroad in this department.

Prof. Crocker also gave some account of the English telegraph and telephone service.

During his address the lecturer exhibited a number of photographs and samples of electric fittings brought from abroad, which served to illustrate his points. In the discussion which followed Messrs. Hammer, Strauss and Egger took part.

AN ELECTRICAL CONTRACTORS' ASSOCIATION IN NEW YORK.

It is understood that an Electrical Contractors' Association has been formed in this city by the concerns engaged in wiring and construction work, including such companies and firms as the Tucker Electrical Company; H. Ward Leonard & Co.; New York Electric Equipment Company; Zimdars & Hunt; Chas. L. Eidlitz; Western Electric Company; Rousseau & Co.; Edwards & Co.; Ostrander & Co.; Interior Conduit Wiring Company; J P. Hall; Bateman & Pollard; Hatzel & Buehler; Haggerty & Co.; Chapin & Co.; Eureka Electric Company; Interior Conduit and Fixture Company. This association will be a member of the United Building Trades Association, and its object is to secure greater freedom for the concerns belonging to it in the hiring of competent and faithful men, whether in the Wiremen's Union or out of it. Each of the members has posted a notice in its office stating that hereafter there will be no discrimination between men in the union or out of it. All labor will be hired simply on the ground of its quality. It is said that there are about 700 men in the Union and 400 outside, and that the proportion of really competent men is far larger in the non-union ranks than in the other group. This new departure has led to trouble already on work now in hand, but the Association claims that it is only acting after long consideration and that it will undoubtedly secure its purpose.

A COURSE OF LECTURES IN ELECTRICITY.

Mr. Elmer G. Willyoung, superintendent of Messrs. Queen & Co.'s. laboratory at Philadelphia, is delivering a course of lectures at the Young Men's Christian Association, Philadelphia, on Thursday evenings, which will continue until March 30, next. The lectures will embrace the science of electricity and its application to commercial uses, and are very exhaustive in their scope. They will be profusely illustrated, as Mr. Willyoung has at his command all the apparatus necessary for practical demonstration.

LETTERS TO THE EDITOR.

THE CONSTRUCTION OF UNIPOLAR MACHINES.

From a consideration of Mr. Steinmetz's theory that a revolving magnet would generate an electromotive force within itself, cutting its own lines of force, it follows, I think, that the field *would* revolve, owing to a resistance to this cutting.

Beyond accounting for the failure of Mr. Balch's second machine (which, I think, he misunderstands, for it was, I believe, Mr. Balch's idea to make the magnets hollow, that the inductor might be coiled through them, but with no electrical connection between the three) by the non-revolution of the field, Mr. Steinmetz says nothing.

What would occur were the fields made to revolve practically as by means of projections at the pole-pieces, he does not discuss, which is, to say the least, a disappointment.

Harold R. Wellman.

Duluth, Minn., Oct. 11, 1892.

COLLEGE NOTES.

COLUMBIAN UNIVERSITY, WASHINGTON, D. C.

The Corcoran Scientific School, of the Columbian University, includes among its courses, one of four years' duration leading to the degree of Electrical Engineer. In addition to the compulsory work in the department, a number of electives are provided, and a thesis is required before graduation. Prof. F. R. Fava, Jr., C. E., is in charge of this department.

JOHNS HOPKINS UNIVERSITY.

The course in electrical engineering will henceforth be accepted as part of the work leading to the Ph. D. degree in physics, and will be a most important and welcome change in the department. Work on the new electrical building is expected to begin within a month, and the structure will be ready for occupancy soon after the winter holidays.

LITERATURE.

Recent Progress in Electric Railways. By Carl Hering; 389 pages, 104 illustrations. New York. *W. J. Johnston Co., Limited.* Cloth, 12mo. Price, $1.

WE are informed on the title page of this curious book that it is "a summary of current periodical literature." If that were so, it would, indeed, be valuable. As a matter of fact, on turning over its pages, we find that the paper with which Mr. Hering has formed a casual connection is mentioned nearly thirty times. Two other papers, not electrical, are mentioned perhaps half a dozen times between them. Are we to understand that this is the author's idea of "current periodical literature," or are we to believe that he was under some malign influence which prevented him from realizing that there are more papers in the world than one? That the paper he most depended on could furnish him with a certain amount of clippable matter is no doubt true, but its pages are very far from embracing all the latest advances in electrical traction. If we look at Mr. Hering's preface we find further proof of the fact that his title page is inaccurate. We are informed that "the numerous electrical and other technical journals which give such a large amount of valuable information, must cover so many fields that their bound volumes are not convenient records in any one branch, besides being of necessity large and bulky, and therefore not handy, for connected reading or for subsequent reference." Hence the preparation of this volume and the promise of more like it. But we do not think that all electrical and technical journals come under this sweeping dispraise, although it may be quite true of the one Mr. Hering is understood to edit in spare hours—both as to its unwieldiness and as to the fact that it is not a good record to refer to. We are frank to say that we consider the form of THE ELECTRICAL ENGINEER peculiarly handy, and that its careful index, with cross-references to each half yearly volume, makes it very convenient for study in any branch of electricity.

Coming to the contents of the volumes, we find them divided up into twelve chapters. Now it would be supposed that if this volume is a record of "current" literature, it would have some recent starting point. But it has not. The very first chapter is entitled "Historical Notes," and like the address of the celebrated burgomaster in Offenbach's comic opera, it begins with "the year one ——." It informs us that in 1835-37, Mr. Frank L. Pope discovered Thomas Davenport. We always had a high opinion of Mr. Pope's ability, but this evidence of his precocity is quite startling. The truth is that last year Mr. Pope contributed to the pages of THE ELECTRICAL ENGINEER a very interesting series of articles on Davenport, but there is no such reference to our columns in Mr. Hering's book, although he is careful to drag in his own paper twice in three pages. Why he should handle historical data in such a way is best known to himself or his publisher. Moreover, the historical notes are not massed in this chapter, but crop up all through the book, and what makes this method of treatment the more confusing is that the book is entirely without an index!

The subsequent chapters deal with statistics, construction, operation, systems, accessories, etc., and appear to have been prepared chiefly with an abundant supply of mucilage and quotation marks, but with no attempt to give due sequence to the narrative. The result is very much that which would be obtained from reading a dictionary. One gets an idea that a great many subjects are touched on, but just what is coming next it is hard to guess. The effect is often grotesque. Papers read before the societies are sliced up and their paragraphs are dropped here and there from end to end of the book, in a "crazy quilt" fashion; so that we get expert advice; daily newspaper editorials; chance opinions; reports of tests; comments of the "compiler"; bits of old articles; and frequent references by page and date to the journal that Mr. Hering says is so unhandy for reading and reference—all mixed up in an olla podrida that only a strong stomach and a crude appetite could enjoy or digest. If anybody has a taste for this sort of thing, here is a great opportunity to indulge, but it is open to doubt whether the electrical public cares for such miscellaneous feeding.

Moreover, many of the citations are unfair and misleading. Thus on page 224 is a quotation from an interview with Mr. F. J. Sprague as to a tunnel system for New York. It is made to appear that this interview was had with a representative of the paper that Mr. Hering carefully names. As an actual matter of fact, the interview appeared in the New York *Commercial Advertiser*, which printed and circulated a special edition in order to forestall the journal named by Mr. Hering, in pirating the matter as its own for distribution at an electrical convention. The interview was given out to the various electrical papers on condition that they would not publish it until the following week, and all of them save one stood by their word.

We might go on and point out many other things in this book worthy of severe criticism, but our space is too valuable. We can only regret that Mr. Carl Hering was so ill-advised as to put his name to such a book, which is simply so much hash and mincemeat. He has done admirable work as an electrical author, and is capable of doing it again; but he should know that such performances as this cannot add to his well-deserved reputation. If it is necessary for somebody's pecuniary benefit that books of this nature must be ground out, let him leave it to men of lower ability. It is true that every electrical book must take more or less note of what the papers print, but brains and not scissors should be the editing implement. We cordially advise our readers to get Mr. Hering's other books, but to let this severely alone. Or if they must read, as they should, electric railway literature, they will find the pages of Crosby & Bell quite adequate to their current wants.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED OCTOBER 11, 1892.

Accumulators:—

Secondary Battery, W. L. Silvey, Lima, Ohio, 484,120. Filed Jan. 29, 1892.

Claim 8 follows: The process of making secondary battery plates which consists in mixing a metallic oxide with the liquid, placing the resulting product on a suitable support, subjecting it to the action of heat, then pickling it in a solution, and forming.

Alarms and Signals:—

Railroad Signal, E. Urbain, Brooklyn, N. Y., 484,068. Filed Oct. 20, 1891.

An electric automatic block signal system for steam railways.

Electric Fire Alarm, H. Cortland, Toronto, Canada, 484,140. Filed April 30, 1892.

Employs a thermostat adapted to first open and then close a circuit, and a clock mechanism for controlling the circuit.

Apparatus for Indicating the Positions of Railway Cars, J. H. Hunter, Pittsburgh, and J. S. Lucock, Alleghany, Pa., 484,205. Filed June 24, 1891.

Employs a chute divided into sections, balls representing the position of a car on its track, and electromagnets and circuit closers for controlling the movement of the balls in the chute.

Device for Preventing Accidental Closing of Electric Circuits in Signal Boxes, W. H. James, Boston, Mass., 484,206. Filed Feb. 16, 1892.

Provides means for preventing the closing of an electric circuit in the event of the breakage of the actuating spring.

Portable Burglar Alarm, D. D. Nolley, Wilson, N. C., 484,232. Filed May 25 1892.

Claim 2 follows: A burglar alarm comprising a battery, a bell, two contact points, one having two co-acting clamping arms for securing it to an object and the other having a screw and connecting wires.

Combined Electric Burglar and Fire Alarm, D. D. Nolley, Wilson, N. C., 484,233. Filed May 25, 1892.

Conductors, Conduits and Insulators:—

Electric Cable Splice, F. A. C. Perrine, Trenton, N. J., 484,045. Filed June 29 1891.

An unfilled cable splice having each spliced conductor surrounded by a sleeve of non-absorbent material, and having a casing outside the group of spliced conductors.

Insulator, F. M. Locke, Victor, N. Y., 484,209. Filed July 13, 1891.

Claim 1 follows: An insulator shank having one end pointed and threaded and the other end solid and channeled longitudinally.

Distribution:—

System of Electrical Distribution, H. W. Leonard, New York, N. Y., 484,208. Filed June 3, 1892.

Claim 1 follows: In a system of electrical distribution a combination of the main generator, the main lamp in multiple arc therewith, the low volt storage battery in series with the main lamps and the low volt lamps in multiple arc with said storage battery.

Galvanic and Thermo-Electric Batteries:—

Galvanic Battery, J. W. Hoffman, Chicago, Ill., 484,096. Filed Dec. 12, 1891.

Employs a zinc cell provided with a plastic lining of starch and an excitant, a moistened filling of crushed coke or carbon, and a depolarizing agent, and a carbon plate embedded in said filling.

Battery Compound, W. Wright, New York, N. Y., 484,385. Filed Dec. 2, 1891.

Consists in subjecting sulphuric acid containing a metallic oxide and a chromium compound to a temperature of 275 degrees Fahrenheit for fifteen minutes, and then spreading it upon a plate cooled to 60 degrees Fahrenheit to become dry and granular.

Lamps and Appurtenances:

Apparatus for Regulating the Intensity of Incandescent Lights, J. F. McElroy, Albany, N. Y., 484,110. Filed July 30, 1891.

Employs an iron frame having an electric coil secured to it and an armature bent near its end in such a manner that the bended portion may be placed within the coil and the other end fulcrumed to the iron frame.

Manufacture of Carbon Filaments, T. A. Edison, Llewellyn Park, N. J., 484,184. Filed Oct. 27, 1886.

Consists in placing the bare filaments in a chamber together with a quantity of lead in unfused condition and exposing the same to carbonizing heat.

Manufacture of Carbon Filaments, T. A. Edison, Llewellyn Park, N. J., 484,185. Filed Dec. 27, 1886.

Employs a chamber for the reception of the filament receptacles and means for suspending said receptacles out of contact with the walls of the chamber.

Electric Arc Lamp, J. A. Hayes, Carson City, Nev., 484,199. Filed June 27, 1891.

A double-feed arc lamp designed for use in work where the light is to be focused.

Incandescent Electric Lamp Socket, C. J. Klein, New York, N. Y., 484,207. Filed Dec. 28, 1889.

Employs an elastic rubber ring surrounding the neck of the lamp and in contact with the edge of the socket.

Measurement:—

Electrical Depositing Meter, T. A. Edison, Llewellyn Park, N. J., 484,183. Filed Sept. 2, 1891.

Employs a ring electrode connected with a weighing apparatus, and a second electrode on two sides of the first electrode.

Miscellaneous :—

Range and Position Finder, B. A. Fiske, U. S. Navy, 483,999. Filed Feb. 13, 1892.

Claim 1 follows: The improvement in the art of finding the position of a distant object, which consists in first determining the fractional portion of a conducting body bearing in length a ratio to the angle of said object and, second, measuring the electrical resistance of said length.

Method of Electrical Refrigeration, M. W. Dewey, Syracuse, N. Y., 484,182. Filed Feb. 8, 1890.

Consists in lowering the temperature in a portion of a conductor and passing an electric current through the conductor to increase the conduction of heat from the warmer to the cooled portion.

Railways and Appliances :—

Electrically Operated Railway Switch, C. A. Stone, Newton, and E. S. Webster, Boston, Mass., 484,123. Filed Sept. 25, 1891.

Employ a pair of switch section conductors each connected through a magnet of the railway switch with the main electrical conductor, the trolley being adapted to make contact with either switch section conductor as desired.

Trolley Wire Insulator, A. Anderson, Boston, Mass., 484,280. Filed Dec. 23, 1899.

Employs an arch shaped frame supporting the insulator and having a channel at its upper side and pins at the lower ends. The span wire extends under the two pins and over the arch, being held into position by the channel.

Trolley Wire Cleaner, E. B. Smith, South Amherst, Mass., 484,344. Filed Feb. 26, 1892.

Employs a frame pivotally mounted at the end of the trolley pole and bearing a clearing device consisting of a hub having a central ridge and series of wings provided with openings.

Switches and Cut-Outs :—

Rosette, C. Wirt, Chicago, Ill., 484,077. Filed Aug. 29, 1891.

Employs circuit closers consisting each of a head cemented into recesses in the rosette cap, and having separated outer ends between and about which the local conductor may be twisted and secured.

Electric Switch, M. R. Utley, Minneapolis, Minn., 484,380. Filed March 5, 1892.

Employs a pivoted lever having contacts on its longer arm, and the upper portions of the end of its shorter arm rounded; a flat spring being arranged to bear against the end of the shorter arm to hold the lever in different positions of adjustment.

Telegraph :—

Railway Train Telegraph, M. S. Reiley, Washington, D. C., 464,375. Filed Jan. 4, 1888.

A railway telegraph employing a fixed conductor upon the bed of the road.

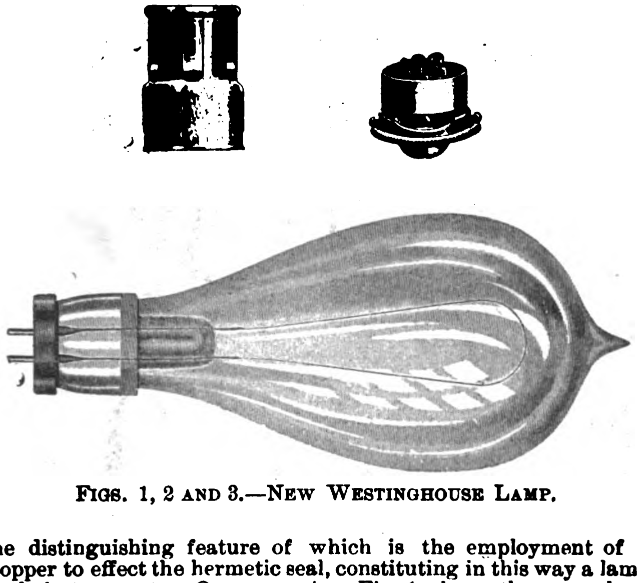
Telephones and Apparatus :—

Magnetic Telephone, C. S. Forbes, London, Eng., 484,150. Filed May 16, 1892.

Employs compound ringing magnets with soft iron pole-pieces carried by one end with a tympan box, and tympan and adjustable polar extensions each carrying an inducing bobbin filled with a conducting wire connecting the line and earth.

THE NEW WESTINGHOUSE LAMP.

As already announced in these columns, the Westinghouse Company propose shortly to place upon the market an incandescent lamp differing in construction from that heretofore in vogue, the distinguishing feature of which is the employment of a stopper to effect the hermetic seal, constituting in this way a lamp made in two parts. Our engraving, Fig. 1, shows the general appearance of the new lamp. The globe is blown separately, with a thick neck, which is ground to a perfect conical surface for the reception of the stopper. The latter, ground to correspond, has fused into it two stout leading-in wires, not of platinum, the ends within the lamp being reduced in size for the reception of the filament.



FIGS. 1, 2 AND 3.—NEW WESTINGHOUSE LAMP.

The stopper, with the filament mounted, is inserted into the lamp, which is then exhausted. Finally, a special cement is applied to the joint outside the lamp for the purpose of affording an added protection against air leakage.

The external ends of the leading-in wires act as the terminals which fit directly into the socket, shown in Figs. 2 and 3. The latter is extremely simple, the terminals being received by spring clips mounted on a porcelain base.

As the stopper holding the filament can be readily removed, the burnt-out lamps can be easily taken apart and new filaments inserted.

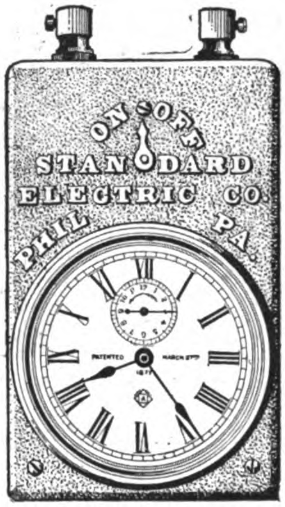
TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

It is a good thing to exhibit at conventions; it is a better to go in for systematic advertising.

THE "STANDARD" AUTOMATIC TIME CUT-OUT.

It is customary, for displaying or advertising purposes, to keep electric lamps burning after business hours, and it is desirable, for economic or other reasons, to cut out the lamps at an earlier hour than the time when the general supply circuit is broken at the central station; and in order to do this, the circuit must be broken at the point of consumption. To effect this automatically, the Standard Electric Company, of 2246 and 2248 N. 9th street, Philadelphia, Pa., have just brought out their "Standard" automatic time cut-out, which is illustrated in the accompanying engraving.



"STANDARD" AUTOMATIC TIME CUT-OUT.

By means of this switch the consumer is saved the annoyance and inconvenience of going himself or sending another person to the point of consumption in order to break the circuit. On account of the inconvenience of this proceeding, it is seldom done, and the consumer, who thus has his lamps in circuit two or three hours longer than he needs or desires them, is saved the additional expense of such unnecessary consumption of current.

With this automatic time switch in the circuit, in place of an ordinary switch, the consumer has merely to wind the clock work and set the "let-off" mechanism, so that it will be released at the desired time; he can then turn on the switch, and leave the device operate automatically. If, however, it is desired to turn off the current before the time determined upon, and perhaps to again complete the circuit, or if it be found desirable to turn on the switch and to turn it off again after the time switch has operated automatically, it can be done without any interference with the automatic mechanism employed in the switch.

ILLUMINATED DESIGNS IN THE COLUMBUS CELEBRATION AT CHICAGO.

The electrical design of the American and Spanish flags over the Grant statue at St. Louis, designed and erected by the Emerson Electric Manufacturing Co., and recently illustrated in THE ELECTRICAL ENGINEER has been reproduced in Chicago on the Auditorium Building during the celebration of the World's Fair dedication. The Emerson Electric Manufacturing Co. furnished the designs and structure for this piece as well as the automatic cylinder operated by a one-eighth h. p. Meston motor, which produces the waving effect of the flags so much admired in St. Louis.

THE SPENCER SPARK ARRESTER.

THE new electrical firm of Taylor, Goodhue & Ames, 827 Monadnock Block, Chicago, are placing a new spark arrester on the market, which possesses a great deal of merit. The previous forms of spark arresters have often been awkward to adjust and clumsy in appearance. The new arrester is well illustrated in the accompanying cuts. Fig. 1 shows the appearance of the spark arrester when properly adjusted to the lamp. Fig. 2 illustrates the manner of adjusting. The clamp on the side firmly holds the arrester in position by securely clamping it on the supporting rod, and as this clamp is adjustable it may be used on lamps with either the supporting rod placed inside the globe or outside. The appearance of the arrester is exceedingly neat and with its novel features it should find a very ready market.

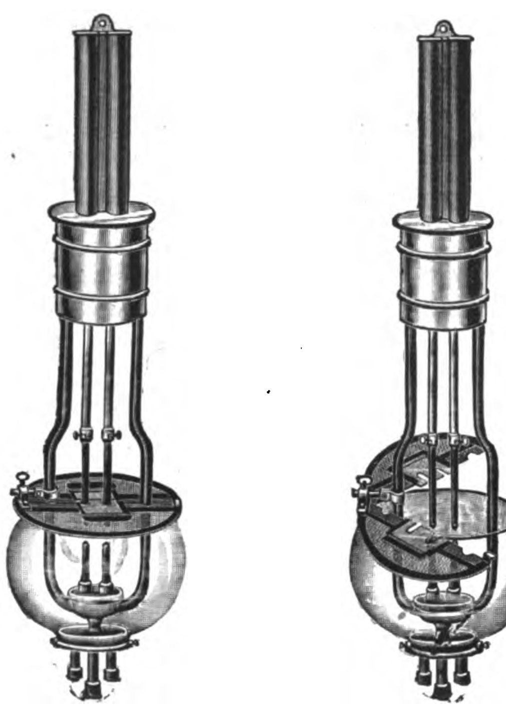


FIG. 1 AND 2.—SPENCER SPARK ARRESTER.

Taylor, Goodhue & Ames call it the Spencer spark arrester, and will be pleased to answer all inquiries and give price upon application.

THE DREXEL INSTITUTE PLANT IN PHILADELPHIA.

WE have made mention before of the immense installation at the Drexel Institute in Philadelphia which was completed about one year ago by Messrs. M. R. Muckle, Jr., & Co. The plant as then installed consisted of three 10 and 18 x 10 inch Westinghouse compound engines driving three large "Special" slow-speed Edison generators which supplied light to about 1,800 lamps throughout the entire building. The plant was of a very mixed description, using Thomson-Houston and Eddy motors, and Sawyer-Man lamps and sockets. Since the plant has been started it has worked with such uniform satisfaction that the same firm received the order a few weeks ago for the fourth engine of the same size and an additional slow-speed dynamo. This was rendered necessary by the large number of motors being installed in the building, and especially by the increasing use of the electric elevator. The throwing off and on of the load suddenly with this elevator when carrying heavy weights would often run the amount of current being used up to such an extent as to endanger the blowing of the fuses when only one or two of the main dynamos were working. As now arranged, all the motors will be run upon the fourth machine so as to prevent overloading at any time, the motor circuits being kept separate from the lighting circuits. The benefit of the Westinghouse compound principle shows in a very marked manner in this plant, since the engine doing this work will run on an extremely varying load. The new dynamo is of course so arranged that if desired it can be thrown in with the other three to help them out on the lighting. It has been determined not to use this electrical plant for the purposes of instruction, but to install a separate dynamo and engine for that purpose. It was not considered wise to risk experimenting with the electric light plant since there is no other means of illumination in the building, and the consequences of any trouble with the lights in an educational building of this size and character might be serious.

MESSRS. NALDER BROS & CO.

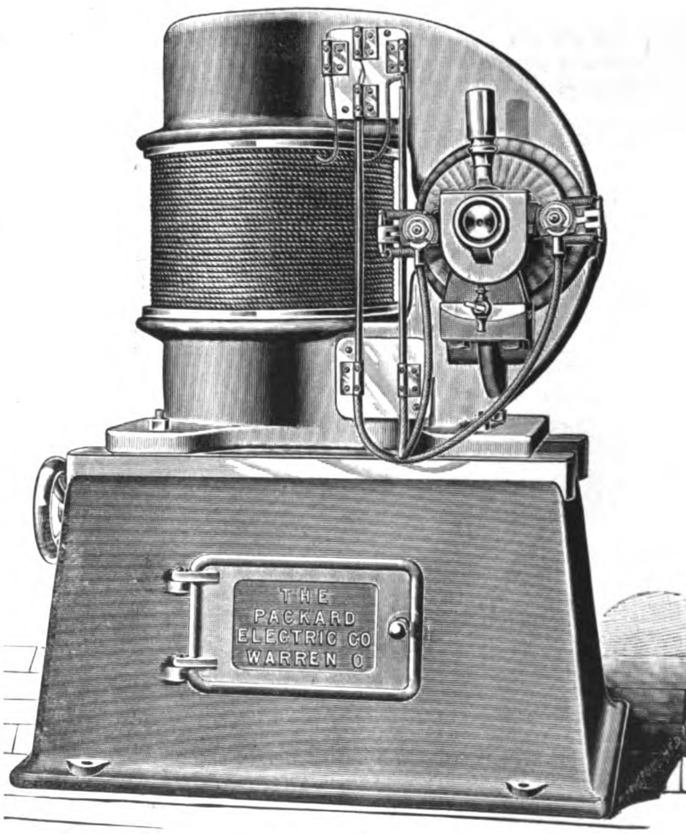
THE fourth edition of the catalogue of Messrs. Nalder Bros. & Co., London, makers of electrical and scientific instruments, contains an eight-page supplement descriptive of new battteries, galvanometers, voltmeters and miscellaneous instruments that have been added to the stock of the firm since the catalogue was issued. Prominent among these is a Kelvin centi-ampere balance for measuring currents from .01 to one ampere.

Both catalogue and supplement are exceedingly well printed and profusely illustrated in blue on heavy paper, and will be found most attractive as well as useful.

THE PACKARD MOTORS AND DYNAMOS.

THE accompanying illustration represents a new design of dynamo or motor built by the Packard Electric Co., of Warren, Ohio, whose New York representative is Mr. Charles E. Chapin, 136 Liberty street. These machines were introduced in view of the increasing demand for small power units at a distance from the centre of distribution, and are claimed to possess very high efficiency. The field is built up of wrought iron bars held in place and shaped by a coating of soft cast iron. The wrought and cast iron unite and form one solid mass, securing a strong magnetic field by the expenditure of a very few watts. There is but one field coil wound upon a movable spool, and but one joint in the magnetic circuit of the machine. The construction is such that the removal and replacement of the field coil is extremely simple. This is a very important item, as every part is built to a gauge, and the voltage of the machine may be thus changed to 110, 220 or 500 volts in a very few minutes. These machines are mounted on a hollow cast iron base which is fitted with a door and designed to be used as a closet for the reception of tools, etc., and are also provided with a belt tightener. They are insulated from this base by hardwood.

The armature is of the drum type and is built up of thin discs securely fastened to a shaft made of the best grade of machinery steel of greatest diameter in its central part. The winding is a modification of the Siemens type, and the armature is so proportioned that there is very little idle wire over the ends. The commutator is constructed of a large number of sections of pure, hard copper insulated throughout with mica, and has ample width of face to secure the best results, and reduce the wear to a minimum. A strong point claimed for these machines is freedom from sparking at the commutator. The brushes having been once set at the non-sparking point, require no changing under extreme changes in load.

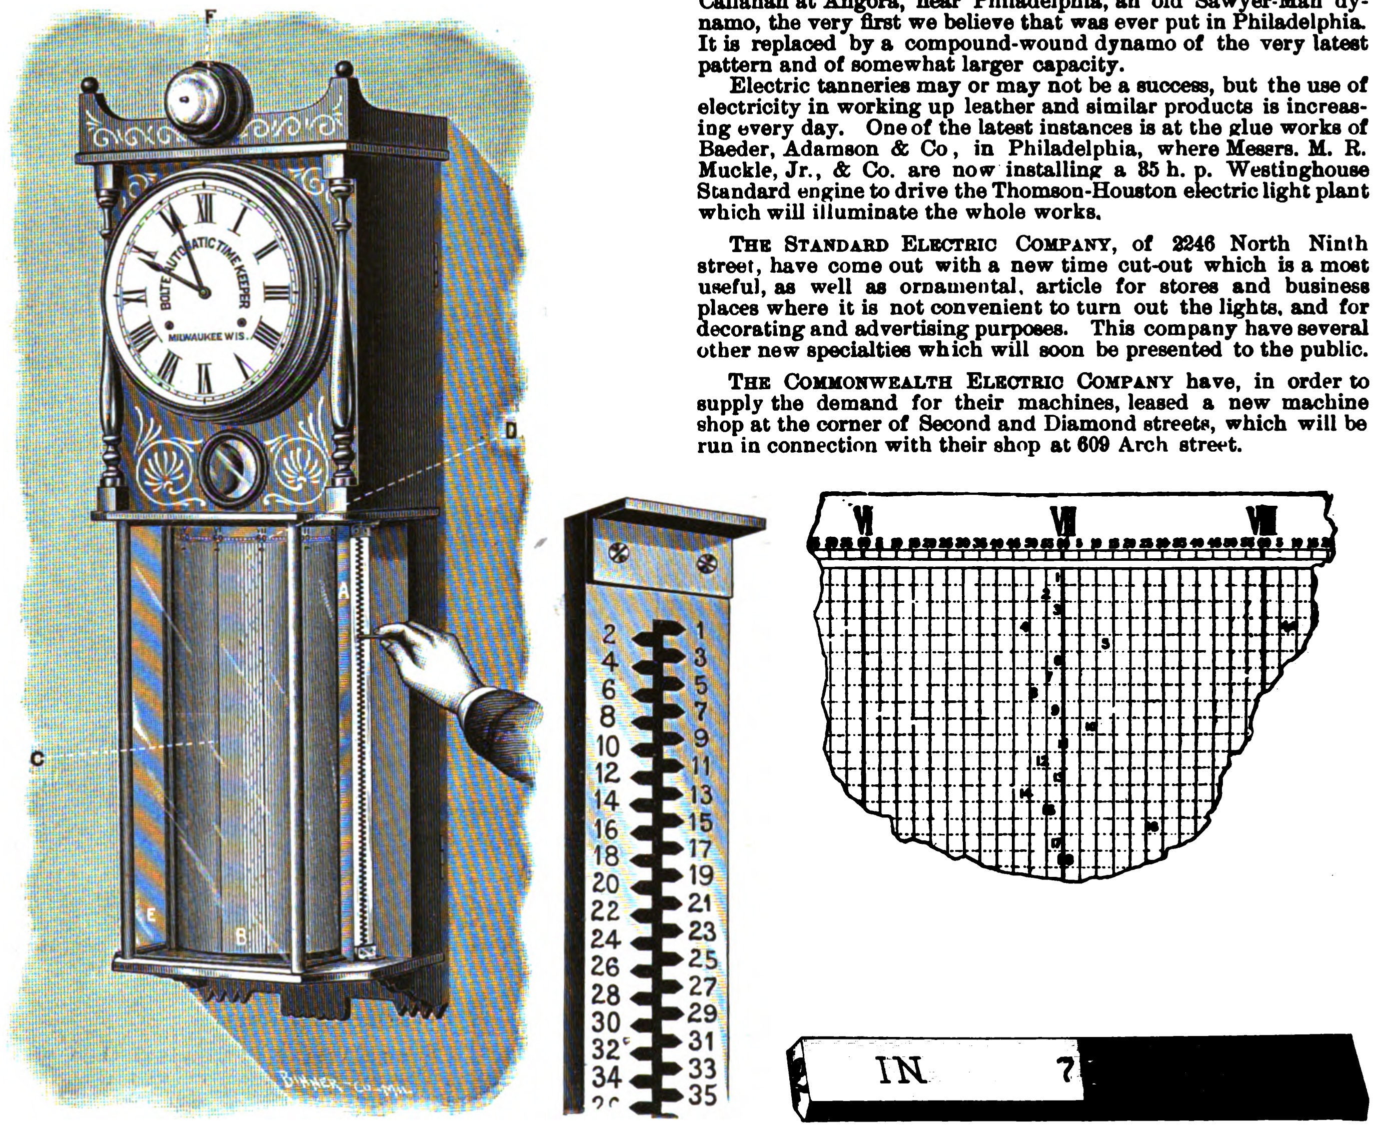


PACKARD MOTOR.

BOLTE AUTOMATIC TIME KEEPER.

The Bolte Automatic Time Keeper is a new device for keeping accurately a record of the time of arrival and departure of employees. Our engraving, Fig. 1, shows the complete detail with clock dial and hand marking the registration.

Fig. 2 shows a section of the upper part of the record sheet. The cylinder around which this record sheet moves turns in time with the hour hand, making one revolution every 12 hours. The heavy line marked 7 o'clock indicates the hour at which the workmen are expected to arrive. The numbers recorded on the left of this line are early, whereas those on the right are late. Each of the light-colored lines indicates five minutes; therefore any one registering three lines to the right of the 7 o'clock line would be 15 minutes late, and as the proprietor enters his establishment in the morning one glance at the clock will indicate those employees who are absent or late, and how many minutes they are behind time.



Figs. 1, 2, 3 and 4.—Bolte Automatic Time Keeper.

Fig. 3 shows a section of the key rack through the openings of which the registrations are made, and Fig. 4 shows the registering key full size. Each workman draws his pay according to a certain number, and in this case the the one shown is No. 75. This number appears in raised letters on each end of the key; the end marked "in" being nickel, the end marked "out" being of copper. The indication of an employee registering "out" is shown by a star (*) being placed after the number, thus; 75*.

The value of this device is apparent. Each workman makes his own registration and cannot complain of the time keeper and on the other hand, no collusion is possible between time keeper and employees. By actual use it has demonstrated the fact that employees are much less liable to be late, as by the use of the Bolte automatic time keeper not only the workmen themselves are able to inspect the record, but their employers are able each day at a glance to ascertain the numbers and names of those who are arriving on time, or others who are habitually late or absent. The device will be placed on the market by the National Time Recorder Company, 361 and 363 East Water street, Milwaukee, Wis.

PHILADELPHIA NOTES.

It was indeed a recalling of old times when Messrs. M. R. Muckle, Jr., & Co. took out from the mills of the estate of George Callahan at Angora, near Philadelphia, an old Sawyer-Man dynamo, the very first we believe that was ever put in Philadelphia. It is replaced by a compound-wound dynamo of the very latest pattern and of somewhat larger capacity.

Electric tanneries may or may not be a success, but the use of electricity in working up leather and similar products is increasing every day. One of the latest instances is at the glue works of Baeder, Adamson & Co, in Philadelphia, where Messrs. M. R. Muckle, Jr., & Co. are now installing a 35 h. p. Westinghouse Standard engine to drive the Thomson-Houston electric light plant which will illuminate the whole works.

The Standard Electric Company, of 2246 North Ninth street, have come out with a new time cut-out which is a most useful, as well as ornamental, article for stores and business places where it is not convenient to turn out the lights, and for decorating and advertising purposes. This company have several other new specialties which will soon be presented to the public.

The Commonwealth Electric Company have, in order to supply the demand for their machines, leased a new machine shop at the corner of Second and Diamond streets, which will be run in connection with their shop at 609 Arch street.

Separate Engines for Lighting Mills.—The advantage of a separate engine for driving the electric light plant of a mill is becoming more and more apparent every day, and as a consequence many of those who in their early installations drove the dynamo from the main shafting are now making the necessary changes. Among others the Thomas Kent Manufacturing Company have just purchased a 35 h. p. Westinghouse standard engine from M. R. Muckle, Jr., & Co. to drive their dynamo which has been in use for several years.

Messrs. Walter C. McIntire & Co., of 506 Commerce street, are overrun with orders for their Crown shade or reflector for incandescent lamps. During October they have shipped 2,000 to Drake, Payson & Whittier, Providence, R. I.; 1,800 to the Edison Electric Light Company, Fall River, Mass.; 1,400 to the Scranton Electric Light Company, Scranton, Pa.; 600 to Manion & Co., New Orleans, La., besides filling many smaller orders throughout the country.

The La Roche Electric Works report that they never before were so pressed with orders for large plants as at the present time. They are running their factory night and day and will have to do so for some time to come.

THE CARPENTER ENAMEL RHEOSTATS.

The latest development in the line of enamel insulation is the issuance of a patent, under date of Aug. 30, 1892, No. 481,781, broadly claiming the fundamental features of enamel rheostats. The patent is issued to Chas. E. Carpenter, and is assigned to the Carpenter Enamel Rheostat Co., of Bridgeport, Conn. The patent was applied for upon February 18, 1891. The Carpenter Enamel Rheostat Company states that the recent decision of the Commissioner of Patents awarding priority to Morford for a similar invention for electric heaters has no bearing on rheostats, as the specification and the claim in Morford's patent is limited to "electro heating apparatus."

The issuance of the present rheostat patent so soon after the Commissioner's decision is claimed to remove all doubt as to the independence of the inventions.

THE RIES REGULATING SOCKET IN PITTSBURGH.

The following is a testimonial received by the Ries Electric Specialty Co.:

Pittsburgh, July 13, 1892.

W. S. Teeple, Esq., Special Agent, Ries Electric Specialty Co.

Dear Sir.—This is to certify that I have examined the Ries regulating socket and find in it all that the company have claimed for it as a convenient and thorough regulator of electric incandescent lighting.

The application of the principles involved, as well as the utility of the invention, are unique, the device being positive in its action, saving in its results, at the same time simplicity itself.

Very respectfully yours,
Morris W. Mead,
Sup't Bureau of Electricity.

A PROPOSED PLANT FOR CHESTER, ILL.

We have received from Mr. J. D. Gerlach, cashier of the First National Bank of Chester, Ill., a prospectus of a proposed electric light, water and ice plant for that and the adjacent towns. A 35 arc and a 1,000 light incandescent dynamo will probably be required, and the alternating system will be used. The electric plant will cost, it is estimated, $16,883. The city is ready to contract for 23 arc lights. The total cost of the three plants combined is estimated at $84,148, and Mr. Gerlach is anxious to form a company to carry out the enterprise.

PECULIAR VALUE OF GRAPHITE FOR ELECTRICAL WORK.

If a stick of graphite is made six inches long and one-quarter inch in diameter, it can be so made that it will possess an electrical resistance of one ohm or 1,000 ohms. Furthermore, if such a stick of 1,000 ohms is cut in three-inch lengths, each length will be found to possess a resistance of 500 ohms. This homogeneousness of the mass enables the electrician to easily solve some difficult problems that would otherwise call for expensive appliances.

For telephone switchboards and other uses where the current is not great and where the resistance is variable on account of induction from near-by trolley wires or other causes, graphite resistance rods have been found very valuable.

Graphite resistance has also been successfully introduced in sockets intended for regulating the light of incandescent lamps, and as the graphite can be formed in many different shapes as well as in varying resistances, the field is a very promising one. The Joseph Dixon Crucible Co., of Jersey City, N. J., have already filled many orders for such material.

WESTERN NOTES.

The Electrical Supply Company have placed upon the market a new Wirt ampere indicator and Wirt volt indicator for stationary work, which are furnished for either direct or alternating currents. These instruments are intended to be left in circuit continuously and are guaranteed unconditionally as to accuracy. This company has also introduced the Wirt lamp-regulating switch for single lights, the principle of which is said to be totally different from other devices of its class.

Taylor, Goodhue & Ames, 827 Monadnock Building, have been appointed general selling and distributing agents for the direct current motors manufactured by the Wagner Electric Manufacturing Co., of St. Louis, and also the direct and alternating current fan motors. These machines possess new features of special merit, and in construction and workmanship rank second to none.

Car Heaters.—The Electrical Supply Co., corner Randolph street and Michigan avenue, Chicago, has secured the general agency for the well-known Carpenter electric heaters. They have already closed some large contracts with electric railways for their entire equipment. The Carpenter heaters have many points of excellence commending them to progressive railway managers.

Peoria, Ill.—The city council has granted the Edison Co. and the Central Co. electric lights ordinances. They put the rate for lamps so low that the companies have not accepted them and probably will not. It is a big reduction in rates that the present company are charging. The Rapid Transit Co. are now running their cars regularly and are doing a good business.

Taylor, Goodhue & Ames, 827 Monadnock Building, report that although so recently organized, the amount of business already received, and the kind reception accorded the new firm, both by their friends and competitors, have been exceedingly gratifying.

NEW YORK NOTES.

The Standard Paint Company continues to enjoy an active demand for its paints and compounds in the electrical field. The Buffalo Street Railway Company have recently placed with the Standard Underground Company, of this city, an order for 50 miles of heavy underground feeders, the outside to be protected by braid thoroughly impregnated with P. & B. insulating compound. This is one of the largest single orders of the kind ever placed by an electric street railway company.

W. S. Chesley & Co., electrical engineers and contractors, Electrical Exchange Building, have severed their connection with the Easton Electric Co., of Brooklyn, and desire the agencies of electric light apparatus and appliances. This company have just completed a new machine shop at No. 24 Morris street, Jersey City, near Cortlandt street ferry, where they have facilities for repairing all kinds of electric light and power apparatus.

The Electric Engineering and Supply Co., of Syracuse, N. Y., have issued notice withdrawing quotations on all goods of their manufacture. New quotations will be furnished on application.

NEW ENGLAND NOTES.

The Beacon Vacuum Pump and Electrical Co., of Boston, have issued a very pretty souvenir entitled "An Illustrated History of Illumination, from Prehistoric Times to the Beacon Incandescent Lamp." The folder is from the Coke Printing Co., of Boston, and contains six views of lights—a fire of sticks, an olive oil lamp of the first century, the tallow dip of later days, a modern oil lamp, a chandelier, and, finally, a Beacon lamp, which is designated as "the lamp of the future."

The Carpenter Enamel Rheostat Co., of Bridgeport, Conn., have quite recently finished doubling their furnace capacity. They are running their works night and day with this enlarged capacity. These rheostats seem to meet with universal approval from electrical manufacturers and engineers. The theatre and street car rheostats seem to be especially appreciated. The fact that these rheostats are cheaper than those formerly used no doubt partially explains the demand for them.

The Jackson & Woodin Manufacturing Co., of Berwick, Penn., have placed the contract for the new car wheel foundry with the Berlin Iron Bridge Co., of East Berlin, Conn. The building will be made entirely of iron, from the designs of the Berlin Company.

SOUTHERN NOTES.

The Brush Electric Company, of Cleveland, Ohio, through their agents, S. W. Trawick, of Atlanta, Ga., and A. D. Dorman, of New York, have just closed a contract with the Mutual Light and Power Company, of Montgomery, Ala., for a complete central station plant, the consideration being considerably in excess of $100,000. The plant will comprise 300 arc lights capacity, 2,500 16 c. p. incandescent lights capacity, 700 h. p. generating capacity, 700 h. p. Hamilton-Corliss engines, 700 h. p. Heine safety water-tube boilers, all necessary shafting, friction clutch pulleys, couplings, etc., and all construction work for arc, incandescent and power circuits. The contract for the complete steam power plant was awarded to the Heine Safety Boiler Company, of St. Louis, represented by S. C. Munoz. The Heine Company have sublet the engine portion of the contract to the Hamilton-Corliss Engine Company, represented by J. A. Vail, of St. Louis. The complete plant must be installed and in operation by Jan. 1, 1893.

Mr. J. M. Zamoiski, of the Ries Electric Specialty Company, has returned from Hanover, where he closed a contract with the Hanover Silk Works Co. for a complete electric lighting plant of 150 16 c. p. lamp capacity.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.

THE
Electrical Engineer.
VOL. XIV. NOVEMBER 2, 1892. No. 235.

The Sprague-Pratt Electric Elevator for High Duty Service.

By

Frank J. Sprague And Chas. R. Pratt.

I.

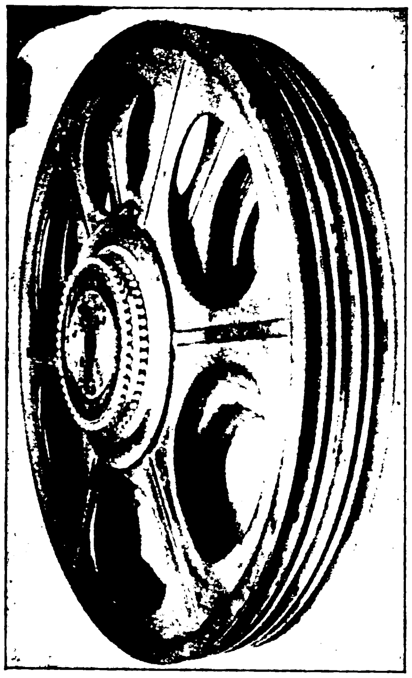


FIG. 1.

ONE of the most important applications of the transmission of power, and one destined to rival in extent the railroad work which has made such great strides in the past five years, is that of the operation of all classes of elevators and hoisting machines.

Some idea of the extent of the present business may be gathered from the fact that in New York alone there are not less than 4,000 elevators of various kinds, more, in fact, than there are street cars.

Assuming for the moment that there will be general or special systems of supply, the business of electric elevators, when fully developed, may be classified as follows:

1st. High speed passenger service where no hydraulic plant is possible.

2d. High speed passenger service in competition with hydraulic plants, the electric plant doing equal duty, costing less, occupying but a small fraction of the space required by the hydraulic, and costing much less to run.

3d. Substitution of new high speed electric service in place of old steam and slow hydraulic service in buildings where the limited space and interference with operations will not permit of any consideration of a new hydraulic plant.

4th. Passenger elevator service in buildings where the loads are comparatively light.

5th. Passenger service in private houses where safety, simplicity and noiselessness are essential.

6th. Freight and special classes of work.

Of the above classes of service the first three may be designated as "first class," and they require speeds of from 300 feet up per minute. The others may be termed "second class," and require speeds of from 50 to 225 feet.

In considering the possibility of electric elevator growth it is hardly necessary to assume sources of supply. The fact is that, independent of isolated plants from which source of power the current can be taken to operate electric elevators, and in addition those which will be put in for the special operation of elevators, there are in the United States alone not less than 350 stations supplying currents of constant potential of from 225 to 250 volts, and engaged in the business of supplying current for electric light and power, and no less than 400 stations supplying similar currents of from 450 to 500 volts for the operation of railway and stationary motors, making a total of not less than 750 electric stations now available.

In addition to these a large number of other general stations will be in operation in the near future, so that the field for work is practically unlimited, and in most places where it is advisable to operate an elevator from a central station there exists, or will soon exist, a station capable of supplying the necessary current.

This growth of electric central station plants is fast making possible elevator service in buildings heretofore denied it, and on account of the greatly increased return from tenants, the rapid introduction of electric elevators is assured.

This latter fact is entirely independent of that business which has already been outlined and which is determined by other considerations.

Having thus generally shown the possibilities of the electric elevator business, we shall, after giving the general conditions of elevator service, and making some special comments upon the hydraulic system, describe in detail, in connection with the specific conditions of elevator service, a new machine, the Sprague-Pratt express electric elevator, which has been designed to meet the first-class service, and which has entered the lists against the hydraulic elevator, and has challenged it on equal conditions of high duty.

To be successful, it must duplicate hydraulic service in movement and safety, and it must do it with collateral advantages. No plan hitherto advanced has been able to cope with the difficult conditions now demanded in fast office work, but it is believed that this elevator has the following characteristics:

It equals the speed and smoothness of the hydraulic.

It will start and stop more softly.

It occupies from one-quarter to one-tenth the space of the hydraulic operating plant.

It costs less than one-half to operate.

It is safer than the hydraulic.

II.

As already stated, there are two general classes of elevator service, and there have been two kinds of machines developed to perform these services when passengers are carried.

The first class has been developed by the increased height of buildings, which has demanded a service of high speed and smooth motion, regardless of cost of apparatus, space occupied, or cost of operation. The hydraulic elevator is the result of this demand, and is the only one that has, up to the present, been accepted for his service. It is to meet this demand—by introducing an elevator which will do the work equally as well as, if not better than, the hydraulic, and which would have the qualities already stated, that the elevator to be described was designed.

The second class of elevator work is that service which requires lower speeds. This applies to small apartment and private houses and other buildings of four or five stories high where light elevator duty is required. This service is excellently supplied by worm gear elevators, which are now becoming popular in electric form, and for which the business will be very large.

The substitution of an electric motor for a steam engine cannot much improve the motion or increase the speed and capacity of the present worm gear machine. This form of elevator was discarded for general high speed service over ten years ago, that is, as soon as the hydraulic set the pace at 300 feet per minute and over.

Nothing can prove the limitations of a worm gear elevator more clearly than the simple fact that, costing less than two-thirds as much to build as the hydraulic, half as much to run, and occupying about one-third the floor space, it never has been used for first-class high-speed service. Several of the leading elevator companies of this country which have built these elevators for over thirty years have spent unlimited skill and money trying to make a worm gear elevator do the work of a hydraulic and be accepted for such work, and thereby command a higher price for that which cost them less to build.

There are few people who buy elevators either for themselves or as agents for others, who care to know upon what mechanical principle an elevator is built. All they wish to know is the speed, load, space occupied, first cost, and cost of operation; the rest they trust to the reputation of the elevator builders. This is not so unreasonable when it is considered that they are limited in their selection: for speeds over 300 feet per minute, a hydraulic from the lowest bidder of the four or five leading companies; for less then that speed, a worm or spur gear in the same way. The comparative merits of such elevators are too nearly equal to be worth special consideration.

What are some of the disadvantages of the hydraulic system? The architect, the builder and the operator are familiar with them. There are of course the necessary boilers and pumps, the latter as used for general elevator service being the most uneconomical of power producers.

The water must be stored in a roof tank of large capacity to which it is delivered through long lines of standpipe which telephones the throb of the pump throughout the building, and which must have special provisions of support; or it must be stored in a compression tank in order to prevent the pulsations of the pump being transmitted to the car, and to give a sufficient amount of water under pressure to start the elevator promptly. This tank requires constant watching by the engineer to prevent the water line from getting low enough to allow the compressed air to get into the elevator cylinder and thereby cause the elevator car to jump up and down in a most uncertain manner; this is not an unusual occurrence.

There must be provided return pipes and an overflow or discharge tank. On account of the position of the pumps and the duty required, the water is almost invariably pumped against a pressure greatly exceeding the hydrostatic head corresponding to the travel of the cars, the pressure in some instances being very nearly double this.

The cylinders are placed either in the basement where they belong, but where they take up valuable space, or vertically in the shaft, thus limiting the size of the cars and cutting up valuable space. Frequent packing of the cylinders is required, leakage is almost always taking place, and both troubles are intensified with the longer runs, greater speeds, and higher pressures demanded in modern buildings.

Erratic jumping or racing of the car because of air in the cylinders, or stretch of the controlling rope, or imperfection of the valve, or lack of skill of the operator are not unfrequent, and creeping of car because of leaky valves is a fruitful cause of annoyance.

Add to this the lack of economy of the hydraulic, and one has the situation in a nutshell.

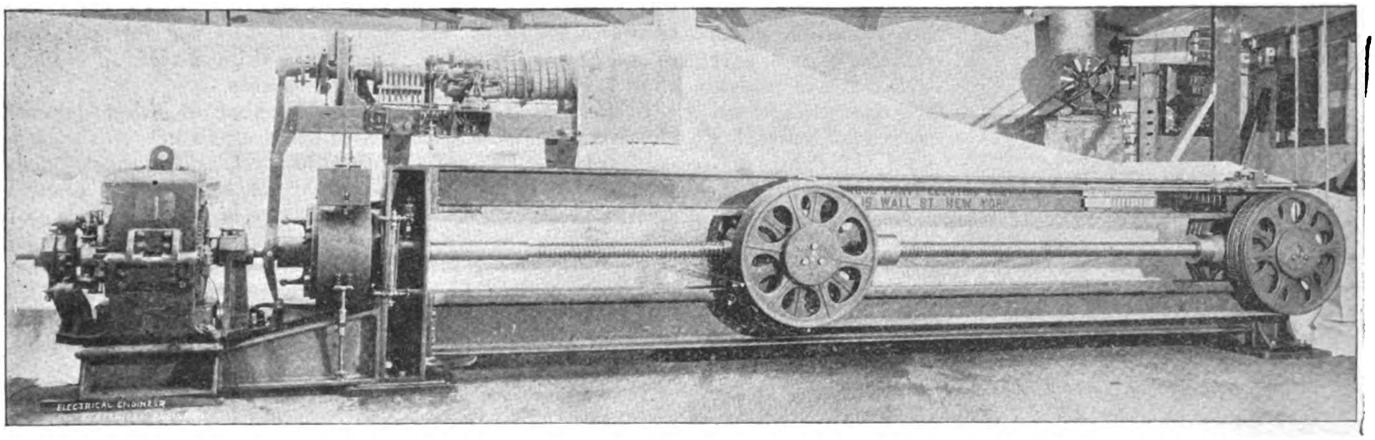

Fig. 2.—General View of Sprague-Pratt Electric Elevator.

III.

Such then being the general conditions of elevator service, let us see how they are met in the machine under consideration, and in order to do that, a brief description of the machine itself as illustrated in a general view in Fig. 2, and in detail in the remaining figures, is in order.

By a reference to the illustration it will be seen that the general character is that of a horizontal multiplying sheave hydraulic machine with a traveling cross-head. There is a main frame having an upper and lower guide and end pieces dovetailed into and bolted to them. Through the middle extends a screw of peculiar construction centered at the outer end and supported by a bearing at the inner end, where is also placed a thrust bearing external to the frame. The screw passes through a compound safety and working nut connected by a friction seat with a forged steel cross-head having trunnions on either side each of which carries a nest of sheaves mounted on ball bearings. Sheaves of the same size and corresponding in number are carried on a spindle anchored at the outer end and from these the hoisting ropes lead to the overhead sheaves. At the inner end of the screw is a brake wheel held normally by a steel and leather brake band anchored on the motor frame
]

and operated through a double toggle joint by the movement of a weighted lever controlled by a shaft and link chains driven by the pilot motor. In line with the extension of the screw is the shaft of the armature of the hoisting motor, which is coupled to the end of the screw by a sliding coupling and which carries also the centrifugal governor. In hoisting, the armature turns the screw, which, operating on the ball nut, moves the cross-head so as to increase the distance between the two sets of multiplying sheaves, and in lowering, the weight of the car on the hoisting ropes draws the sheaves together, and through the ball nut revolves the screw and turns the motor. The motor takes current from the line in hoisting, but in lowering it is cut off from the line and is operated as a driven dynamo by the falling weight of the car. The controlling apparatus is carried above the brake strap on the inboard end of the frame, and consists of a pilot motor controlled from the car, a secondary controlling switch through which the car switch operates, a rheostat connected to a peculiar spiral switch, and a making and breaking switch and brake chains likewise operated by the pilot motor.

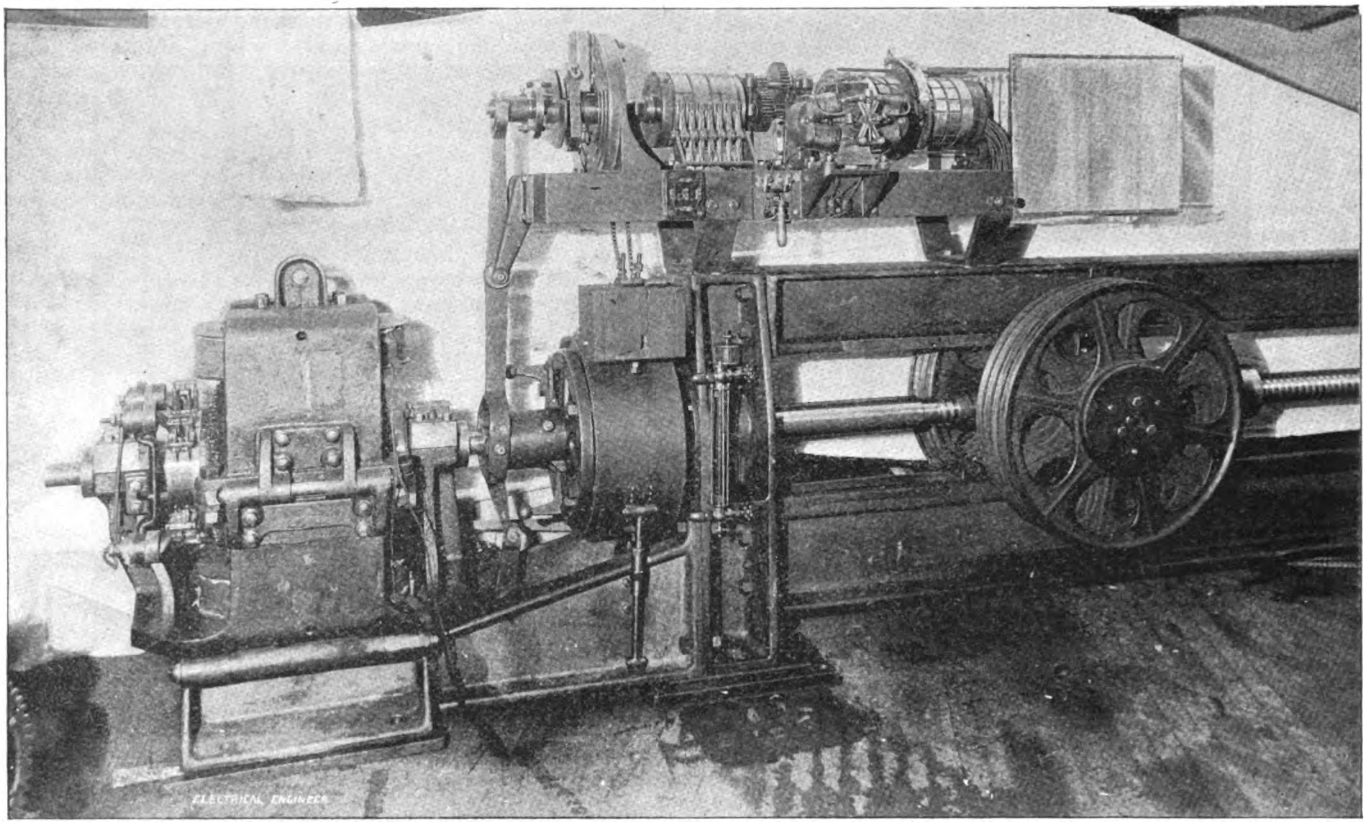

Fig. 3.—Front View of Motor End of Elevator.

The thrust of the screw being taken up on the inboard end, the strain on the screw is invariably between that end and the traveling cross-head, and never beyond this; hence, it is always under extension, never under compression.

The function of the brake is that of locking the screw when at rest, and not a means of varying the speed. In case of accident it has the additional function of helping to stop the screw.

The operation of the various parts will be more apparent in the detailed description of the elevator's functions. The remaining figures are as follows:

Fig. 3 shows the front view of the motor end of the elevator, with the cross-head near the upper limit, with the regulating apparatus in normal position, the brake lowered and the screw at rest. It shows, also, in detail, a part of the safety apparatus, mainly the operating lever, which, being moved at one end by either the centrifugal brake, or through a rock shaft by the upper travel of the cross-head or by a gravity drop in case the current fails, releases certain cams in the regulating switch, breaking the hoisting circuit, if need be, closing the circuit of the armature locally, and dropping the brake-band upon the brake pulley.

Fig. 4 shows a back view of the same end of the machine, with everything in its normal condition. The additional feature which is illustrated is the upper limit safety, the gravity drop, locked when the line circuit is closed, and the magnetic release in case the line is open.

Fig. 5 shows an end view of the motor end of the machine with the motor disconnected and pivoted out of position, leaving the brake apparatus and thrust-bearing free of access.

Fig. 6 shows the trunnion cross-head with one set of sheaves removed but with the operating ball-nut and the safety nut in place.

Fig. 7 shows the same cross-head with the parts of the nut disassembled.

Fig. 8 shows the machine generally disassembled; the brake, thrust bearing and automatic devices removed, the nuts and ropes off, the motor pivoted out of position, and the screw partially withdrawn. This complete disassembling of the machine can be done within an hour, and it can be restored in a similar time.

Fig. 1 shows one set of sheaves with the outer sheave removed and the ball-bearing exposed.

Fig 9 is the operative switch of the car; its functioning will be described later.

Fig. 10 in an architect's diagram.

IV.

In considering whether an electric elevator merits the attention which may be claimed for it, attention should be given to the specific conditions of passenger elevator service. These are to be considered in the function of hoisting, lowering, and the operation of the safeties.

The function of hoisting involves:

1st. *A smooth running and reliable motor under absolute* *control.*

However the motion of the prime motor is transmitted to the car, it is, of course, essential that the movement of that motor shall be perfectly smooth and even, and that changes in its speed shall be progressive and without shock. Since, also, the movement of the car is coincident with that of the motor the control must necessarily be absolute in order for the car movement to be safe.

The question of control of the motor for elevator work has been much discussed, and it can only be satisfactorily determined in connection with the duty demanded of an elevator, and will be settled by first cost, effectiveness, and eventual economy.

In this connection a few facts are interesting. In fast office work the elevator hoists from one-fifth to one-sixth of the time on duty. In hotel and less severe office duty the hoisting time varies from one-ninth, as in the Auditorium, Chicago, one-tenth, as in the Gerlach, and one-twelfth in the Grand, New York, to one-fifteenth and even one-twentieth in other work.

Considerations of economy as well as first cost and effectiveness have then led to the adoption in this elevator of a motor having a light shunt field, variable at will, a strong series coil, and a rheostat for governing the inlet of current in hoisting, and for governing the dynamic action in descending.

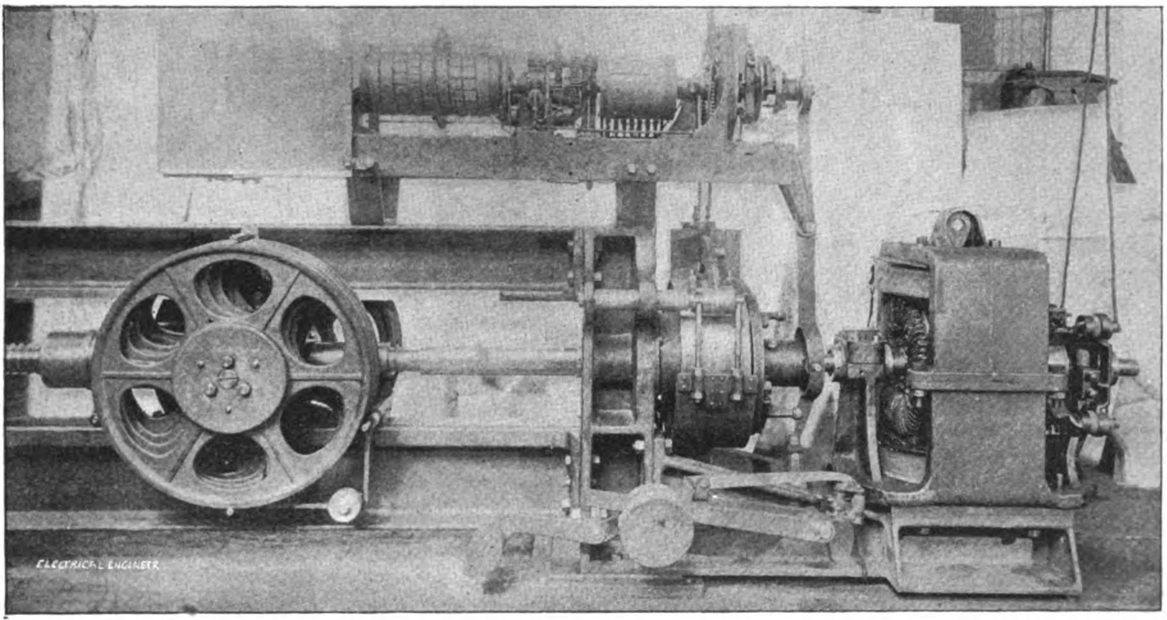

FIG. 4.—BACK VIEW OF MOTOR END.

A year's experience has demonstrated beyond question this to be the most economical method.

2d. *A gradually accelerated start independent of the skill or humor of the elevator boy.*

There are few people who on entering a fast elevator car do not watch the operator and involuntarily brace themselves to resist the sensation of being tossed into the air or of having the floor fall from under their feet. It is not necessary to attain a high speed to produce this sensation, nor is it necessary to produce this sensation in attaining a high speed. The car cannot start too promptly in response to the car switch, but once started, its maximum acceleration should be in a fixed time, as fast and no faster than is consistent with bodily comfort.

If all elevators had the same rate of acceleration of speed that this electric elevator has, people would think no more of stepping into an elevator car than of going from one room to another.

Having determined upon an electric motor as the driving part of an elevator system, it was but logical to make use of a pilot motor to replace the ordinary hand rope. By the operation of this pilot motor results are obtained as follows:

In hoisting, the switch lever in the car is thrown to the "up" position, closing the circuit through the controlling motor, which after having first closed the circuit through the armature of the hoisting motor, the fields of which are separately excited, and having cut out sufficient resistance to prevent the car load from driving the armature backward, raises a brake from contact with the screw and armature shafts, and continues to cut out resistance until there is sufficient current to start the hoisting motor, and if the controlling motor be allowed to finish its run, it will cut out all the resistance and put the hoisting motor to its full speed.

This operation could, if desired, put the car to full speed in less time than most hydraulic elevators can be with a shipper rope. Or it could be adjusted to take any length of time desired, but however it is adjusted, it determines absolutely the minimum time of attaining full speed by movement of the car switch, or its maximum acceleration of speed. It is obvious that with this arrangement properly adjusted no careless or vicious elevator boy can cause discomfort to the passengers.

To stop the car in its ascent the car switch lever is returned to the central or "stop" position, which movement closes the circuit in a reverse direction through the controlling motor, which cuts in the resistance to the hoisting motor armature's circuit, applies the brake, and opens the circuit.

3d. *A start that will not seriously affect the lights on the same circuit.*

This condition can, of course, only exist on a circuit capable of maintaining its potential under the full working load of the hoisting motor, which condition exists in the best public lighting circuits, and where this is not the case the demand for this power current will create the supply.

Such a circuit being given, it only remains to adjust the elevator switch to suit the capacity of the circuit, which adjustment is capable of wide variation. There are few good circuits which through the action of this switch will not permit of as rapid start as is desired on the score of physical comfort. Here again the fixed time element of starting is necessary to prevent disturbance to the lights through the carelessness of the elevator boy.

4th. *Control by the car switch that will enable the operator to make the most limited movement required.*

This operation is effected by the instantaneous response of the motor to the switch movement, the fine gradation of the current, and the freedom from friction of the whole system.

5th. *Any desired variation of speed by the car switch for any distance of travel.*

To accomplish this result three conditions are necessary :

a. Resistance that will not overheat.

b. A switch with a sufficient number of contact points to keep down the difference of potential between points to a non-sparking and a non-heating condition.

c. A high-breaking speed of contacts to prevent arcing.

d. A switch with sufficiently large contact points to insure full carrying capacity on each clip or point.

In short, to make a rheostat that will carry the hoisting motor's current with the switch brush in any position, taking in any portion of the resistance, for any length of time, without dangerous heating of the resistance and without injury to the brush or contacts.

This condition is sometimes necessary where two or more elevators are running together, as may be the case where one elevator has to stop at several stories going down and the other has a straight run to make to an upper story ; in order for the latter not to catch up with the former and break up the alternating time table, it must in some cases run very slow, whichever way running.

The construction of the rheostat makes it practically fireproof, and the total resistance is such as will prevent burning the contacts at the last break in stopping.

This resistance is divided into a large number of divisions so as to reduce the potential between successive contacts. The resistance sections are connected to bronze contact plates of large area and ample carrying capacity. As the arrangement of contact points has to be extended to the lowering end of the switch, they would, if developed into a straight line, occupy over 10 feet lineal space, or a circle over three feet in diameter.

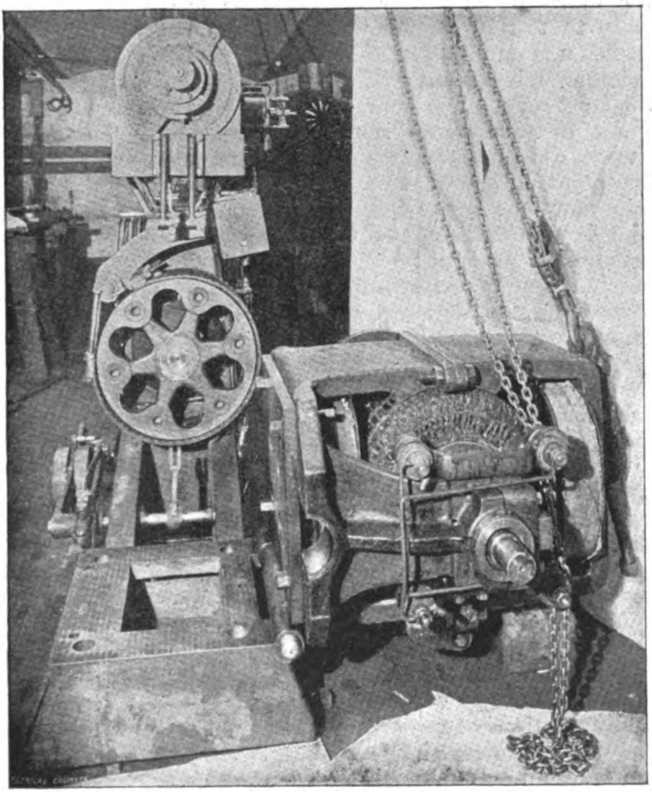

FIG. 5.—MOTOR DISCONNECTED.

To put this into compact form, a spiral arrangement of contacts is used, over which a carbon brush travels at a high speed. The contact plates are screwed to the outside of a hollow cylinder, and wires from the rheostat lead to the inside of this cylinder and through its walls to the contact plates.

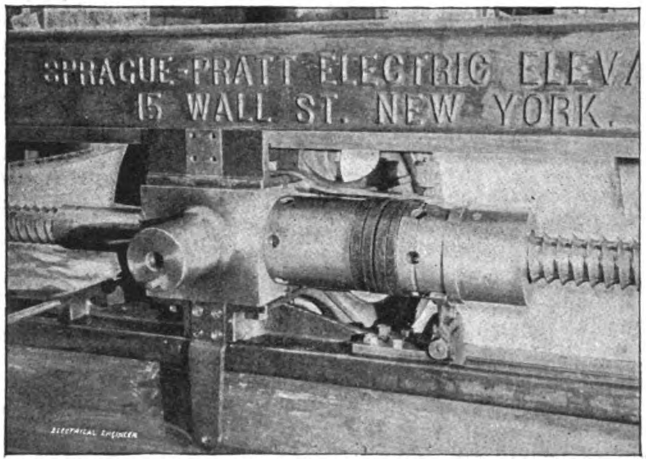

FIG. 6.—NUT SYSTEM, SPRAGUE-PRATT ELEVATOR.

The controlling motor which regulates both the hoisting motor circuit and the brake is under perfect control of the car switch, and also cuts out its own circuit and stops itself at the extreme up and down positions, and returns the main switch to stop with the brake applied when the car switch is put to the stop position in the car.

Its connection to the car switch is made by four copper wires laid in a flexible cable looped to the elevator car from a point half way up the hoistway.

6th. *Unlimited speed at an absolutely smooth motion.*

This, in the Sprague-Pratt elevator, is a condition inherent in the general principle of the machine.

This is obvious when it is considered that the transmission of power developed by the revolving armature of the electric motor is communicated direct by means of a nut and screw to precisely such multiplying sheaves as are usually driven by the piston of a hydraulic elevator cylinder. Substitute a frictionless nut and screw for the hydraulic cylinder, attach the nut to the cross-head of the travelling sheaves, revolve the screw with an electric motor, and one has the fundamental principle of this elevator.

Experience having shown that the multiplying sheaves of the hydraulic elevator were the best means of communicating a perfectly smooth high-speed motion to the car, the problem resolved itself into the question of what was the best means to operate these sheaves without the expensive complications of a hydraulic plant.

The only way to do this with no vibration and perfect safety is by a nut and screw, and to obtain a perfectly even acceleration to the speed at which this screw must be revolved and a perfect control of same the electric motor is peculiarly adapted. Taking for example an elevator of 8 multiplying sheaves, the traveling sheave carriage will move one-eighth as fast as the car; assume the pitch of screw to be one inch; then for every revolution of the motor, the car will rise eight inches, and 450 revolutions per minute of the motor will give a speed of 300 feet per minute to the car. Suppose the elevator to have 12 multiplying sheaves, and the pitch of screw to be two inches and with double thread; then for every revolution of the motor the car will rise two feet, and 450 revolutions per minute will give a car speed of 900 feet per minute. This range of speeds covers any demands for high-speed service, and is safely within the capacity of this type of elevator, which is capable of arrangement for any speed between these limits. An unpleasant sensation sometimes felt in a hydraulic elevator, even when the apparatus is in perfect order, is due to the pulsation of the car caused by air getting into the cylinder, and is occasioned by carelessness on the part of the engineer. Of course this cannot occur in the electric motor and there is nothing between the motor and the car cables to cause a pulsation or vibration except the elasticity of the cables themselves.

7th. *An automatic stop operating at or just above the upper story, that renders it absolutely impossible to drive the car into the overhead timbers and break the ropes, or bring any undue strain on the hoisting apparatus.*

In the first place there is on this hoisting machine a trip operated by the traveling sheave cross-head which applies the brake and cuts out the hoisting current at or just above the upper story. In addition to this there is an absolute and safe automatic stop to the hoisting ropes embodied in the simple action of the hoisting nut and screw, as follows: The screw revolves and the nut travels along the screw, therefore the nut must be held from revolving in order to transmit motion to the car. The nut is so held merely by the friction of the pressure of the load, increased by the multiplying sheaves, and applied to the nut by the cross-head on which the sheaves are mounted. At the end of the screw at which the nut arrives when the car has reached the upper story the thread terminates and a solid collar is there placed, and when the nut meets this collar it locks with the screw, revolves with it without stopping the motor or straining anything, but effectually stopping the car without preventing its being lowered again by the operator in the car.

Any automatic stop to cut off the hoisting power and apply a brake is liable to fail, and such failures have caused accidents. In this machine such an accident is impossible, and there is no other elevator built on this principle.

8th. *Means for preventing the car from descending, or any injury occurring to the switches or motors, in case of an interruption of the current.*

It is a simple matter, and often used, to introduce an electromagnet into the hoisting circuit which releases the brake and holds the car from descending if the current fails. But suppose this is all that is done, and the current was only interrupted for a second or two, as sometimes happens, and the operator has left his switch closed for full speed up; then this may be the result: The motor is at rest, the brake is on, and the full force of the line is closed without resistance through the motor. The result will be either the fuses will blow out or the armature will be injured, and in either case the car will be put out of operation until the damage is repaired by some one outside of the elevator car.

In this elevator an electromagnet in the shunt field circuit not only applies the brake, but also returns the main switch to the neutral point at the same instant, thus preventing injury to the electric apparatus upon resumption of the line current. In hoisting, however, this action does not take place until the car has stopped its ascent, for the following reason: The shunt fields being separately excited have their terminals joined to the same line wires that feed the armature; when the line current fails, or the main fuses blow from an overload, the fields are left in series with the armature, and while the armature continues to revolve by its momentum after the current has ceased, it generates sufficient current through the locking magnet to hold its armature until the hoisting motor stops. This time of this action can be varied at will so that the magnet will drop its armature the instant the line current stops, or retain its armature by over-saturation until the hoisting motor has stopped and reversed a few revolutions. The advantage in delaying this action until the car stops naturally is to prevent the slacking of the hoisting ropes by a sudden stopping of the hoisting machine caused by the failure of the current and application of the brake at the same instant while the car is going up at full speed.

In descending, the action of the magnetic stop is instantaneous but still brings no strain on the car.

9th. *Highest possible efficiency.*

The transmission of power from the motor to the car platform is entirely upon rolling friction, consisting of half-inch hard steel balls rolling upon hard steel surface. It is evident that this system is materially more efficient than a worm-gear elevator, and would consume about one-half the power for equal hoisting rope duty that the average worm gear elevator would consume.

The total efficiency of this elevator, reckoned from the electric energy supplied to the motor to the work performed at the hoisting ropes, is about 50 per cent. as against about 25 per cent. for the hydraulic.

The wasted energy in the hydraulic system is partly due to the fact that for every foot the car is raised, the same amount of water and under the same pressure is supplied whether the car be full or empty. The average load applied to the hoisting ropes of a passenger elevator is not over two-fifths the maximum. Then, again, the pressure is greater than is equaled by the hydrostatic head corresponding to the car travel.

The energy expended is therefore that exerted at the hoisting ropes at the maximum load plus that lost in overcoming mechanical and water friction, and this is further augmented by the low steam efficiency of the pump.

A careful investigation was recently made of one of the most extensive and important modern hydraulic plants, equipped with the best machinery supplied by two of the leading makers, to determine the power required to operate them for a period of 24 hours. This investigation has shown beyond dispute that it takes from 60 to 70 pounds of water for every horse power delivered to the water column, and that the efficiency of the elevator from that point on is only about 25 per cent. This, it is to be remembered, is a plant where there is every reason to expect the most economical hydraulic performance.

An electrical comparison is here in order. The experience of the past year has demonstrated that on this identical plant, if operated by electricity, there would be delivered to the motor terminals only one-half of the energy that is now delivered to the hydraulic column, and when taking into account the difference of economy of operation of a steam pump on hydraulic service and an engine and dynamo operating a general electric service there would be consumed only *one-third of the coal for this elevator system if operated by electricity as there is now consumed as operaated by the hydraulic system.* These statements cannot be gainsaid, and it is no wonder that one of the leading architects of the United States, who has had abundant opportunity to gain a practical knowledge of both systems, pronounces this electric elevator to be, in all probability, a controlling factor in the elevator industry of the country, and that a well-known builder has stated that the performance of this machine marks a revolution in the elevator industry.

V.

The rolling friction is applied as follows:

There are two separate nuts, one of which transforms the revolutions of the screw into a straight line motion of the travelling multiplying sheaves. This is called the hoisting nut. It engages twelve of the screw's threads, or more strictly speaking, twelve convolutions of the screw's thread, and between its thread and the screw thread there are 300 half-inch hard steel balls. These balls place the transmission of power between the nut and screw upon purely rolling friction; no part of the nut touches the screw, and the balls are circulated from end to end of the nut by a tube, each end of which enters the ball-way between the threads of the nut and screw. As the balls emerge from one end of the nut they enter this tube, which returns them to the other end of nut, where they re-enter the ball-way, traveling at from 50 to 75 balls a second past a given point. The introduction of rolling friction at a nut and screw is one of the secrets of the high efficiency of this elevator, every part of which in the line of transmission of power from the motor to the car is on rolling friction. For example, the thrust of the screw is on ball bearings, and the multiplying sheaves are on hard steel ball bearings, which with the ball nut, complete the transmission of power.

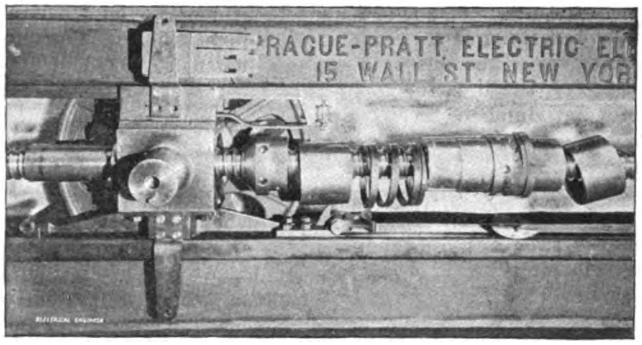

FIG. 7.—PARTS OF NUT SYSTEM.

An interesting test was recently made on a Fairbanks testing machine in New York to determine the liability of balls crushing under normal or extra working strain, and to settle once for all any doubt as to their ability to stand the duty required of them. Ten balls of two different makes were put under crushing strains, and required from 20,000 to 40,000 pounds to break each of them. Since the working pressure varies from 50 to 125 pounds, giving a safety factor ranging from 160 to 880, there would seem to be margin enough to satisfy the most exacting.

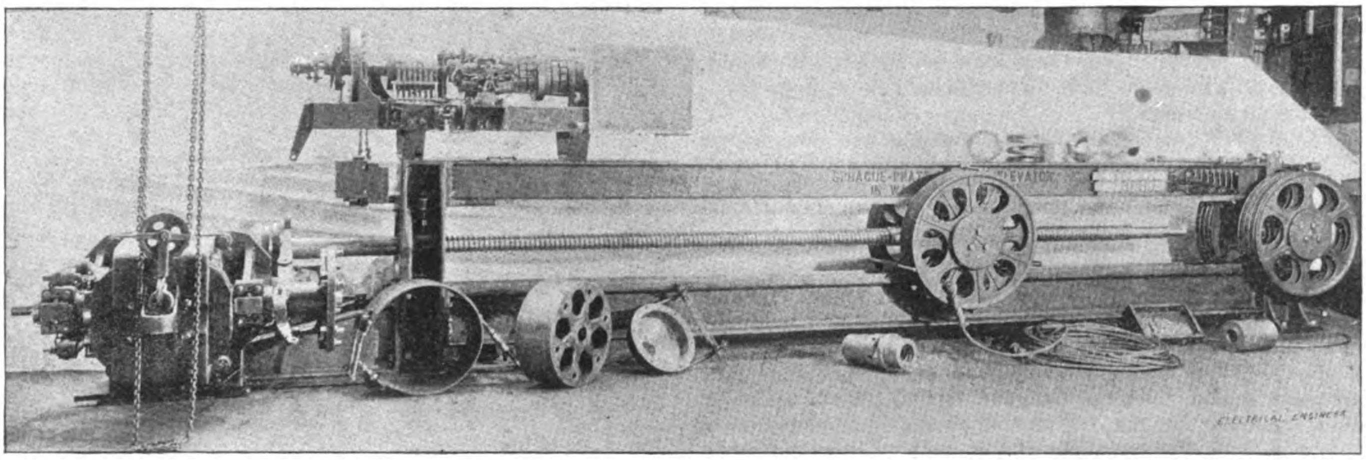

FIG. 8.—GENERAL VIEW OF ELEVATOR WITH PARTS DETACHED.

All those who are familiar with the operation of ball bearings are aware that there are many difficulties to overcome, and these difficulties are such as have led many people to generally condemn the ball bearing notwithstanding its freedom from friction. It is unnecessary to here enter into the the reasons for the many failures, or to explain how difficulties have been overcome in this machine, for these are in the nature of trade secrets. That the difficulties were many is apparent when it is stated that it took over a year to learn how to make the ball nut itself, and the mechanical features now characterizing it and the physical treatment of the metal itself are about as essential as putting the eye into the point of a needle for a sewing machine. There seems to be no other way of getting at the result required except by the methods adopted. So free is this machine from static friction that it is possible to start the car at a very slight increase of current over the normal hoisting current provided time be taken so that the work done in acceleration is small compared to the work of lifting.

Looking at it in a reverse way, the fact that a small weight on the hoisting ropes can overhaul the entire machinery, and revolve the screw, although having only one inch pitch, and promptly accelerate it to several hundred revolutions per minute shows how free from friction the machine is.

Other operative elements will be described later on under the head of Safety.

VI.

THE FUNCTION OF LOWERING INVOLVES:

1st. *A gradually accelerated start independent of the skill or humor of the elevator boy.*

The operation is as follows: The car switch being thrown to the "down" position causes the controlling motor to begin to release the brake at once; the hoisting motor armature terminals being already short-circuited with no resistance in, and the fields separately excited, the moment the brake is released the screw is left under the control of a dynamo with separately excited fields and armature short-circuited on itself, thus forming a resistance which allows the car to move only at a very slow speed. As the switch movement is continued the brake is fully released; more resistance is cut into the armature circuit. and the car is now free to descend more freely because the pressure of the car load transmitted by the multiplying sheaves to the hoisting nut causes the hoisting nut to revolve the screw, and as the controlling motor cuts in more resistance to the armature circuit, the dynamo resistance to the turning effort of the screw is diminished, and the screw revolves faster under the steady pressure of the nut.

As in the start in hoisting this acceleration is capable of any adjustment, but only by this application of rolling friction can any kind of a screw-hoisting machine be made to reverse its hoisting action by simply releasing the brake and then attain a prompt start down and as rapid acceleration of speed as is desirable.

2d. *A gradual stop likewise independent of the elevator boy's personality.*

This condition is necessary in order to avoid straining the hoisting machine as well as for physical comfort, and is attained in this elevator by returning the car switch to the "stop" position, which simply reverses the operation of starting down.

3d. *Control by the car switch that will enable the operator to make the most limited downward movement required.*

This is essential for all refined high-speed work, and the control of this elevator is so perfect that movements of one-quarter of an inch are readily made.

4th. *Any required variation of speed by the car switch for any distance of travel.*

The Twenty-third St. elevator, having a maximum speed of 400 feet per minute, can make a run down of five stories at a speed of ten feet per minute without working the car switch after starting, or can make a run of a few feet at the rate of half a foot per minute, which means a motor and screw speed of three-quarters of a revolution per minute, with the regularity of a clock.

This motion clearly demonstrates the mechanical efficiency and electrical control of this elevator.

5th. *Unlimited speed at an absolutely smooth motion.*

By unlimited speed is meant anything up to about 900 feet per minute. Such speeds would be practical with worm-gear elevators in lowering, but as their capacity for smooth hoisting under heavy loads is practically limited to about 225 feet per minute, it would be impracticable to run them down at four times their hoisting speed.

The absolutely smooth motion in lowering obtained by driving the motor as a dynamo by the weight of the descending car is only possible by using separately excited fields. Suppose the dynamo-motor to be at rest, and either shunt or series wound; when the brake is released and the car load applies its energy to revolve the armature there is no field present to resist the turning effort, and the car is allowed to fall rapidly until the dynamo has built up its own field; it then checks the car quite suddenly, the speed is reduced, the fields weaken and the car speed accelerates again. This intermittent action is repeated all the way down, but with less variations of speed. It would, however, require more than three stories' run to make these jerks imperceptible.

6th. *An easy, absolute, automatic stop at the lower story.*

There are two means of accomplishing this in this elevator. The first is by the simple action of the nut and screw, as follows:

At the end of the screw to which the nut arrives when the car is at the lower story, is placed a spring buffer composed of elastic rubber washers and thin steel discs. When the nut meets this buffer it acts as a brake to slow down the screw, and if the pressure is sufficient, it will, after compressing the buffer about 1½ inches, or one foot travel of car, lock and revolve with the screw, and thus as in hoisting, stop the car without stopping the motor. This stop is no more sudden than is often met with in practice in the best hyraulic elevators, and is absolutely safe and reliable.

In addition to this, for the sake of physical comfort and to save wear and tear on the machine, there is arranged a series of variable resistances, a circuit through which is established by a carbon brush on the traveling sheave cross-head moving over bronze contact plates. The first contact is made at about 6 feet from the lower story, and reduces the resistance so little in the armature circuit that its effect is scarcely felt in the car; from this point to the lower story the resistance is gradually cut out till the armature is short-circuited, and the speed made so slow that the nut which is finally stopped by the spring buffer only compresses it about one-half of an inch, equal to four inches motion of car, and thus forms the softest possible stop.

The softness of this automatic slowing and stopping even when dropping at 400 feet a minute is almost incredible.

7th. *Means for applying the brake in case of any accident to the motor circuit.*

In lowering, this action takes place instantly, as the electromagnet, the same one described in hoisting, has its circuit entirely broken in this case, and the brake is at once applied.

VII.

Safety.—In this connetion consider the hoisting machine apart from all electric and other safety devices.

First, the screw; this is a bar of special forged steel under tension and torsion strains, and capable of sustaining twenty times the heaviest load applied to it.

Second, the hoisting nut; this is of special steel hardened and finished by a special process, and has shown almost no wear whatever in a year's severe run under conditions particularly onerous.

In addition to this is a safety nut. This nut is normally out of contact with the screw's thread; it is secured to the hoisting nut, and should any accident happen to the latter which would break its hold on the screw's thread, this safety nut, the thread of which interlocks with the screw's thread to a greater depth than the thread of the hoisting nut, would then take the place of the hoisting nut, and form an anchorage to hold the traveling sheaves with a grip exceeding the strength of the screw. This would put the elevator out of operation, as the friction between this nut and the screw is greater than the friction caused by the pressure of the traveling sheave cross-head against it; this nut would then act simply as a collar on the screw, and revolving the screw would then transmit no motion to the car. It is obvious that the only part of this elevator that could wear out so as to allow the car to fall if there were no safety nut is the threads of the hoisting nut or screw. Therefore, having a safety nut which is subject to no wear and the thread of which reaches nearer the centre of the screw than does the thread of the ball nut, a condition of safety is reached which is independent of the wearing out of the machine, and also independent of any automatic safety devices. But it may be remarked that special processes of manufacture amply tested by severe duty, insure

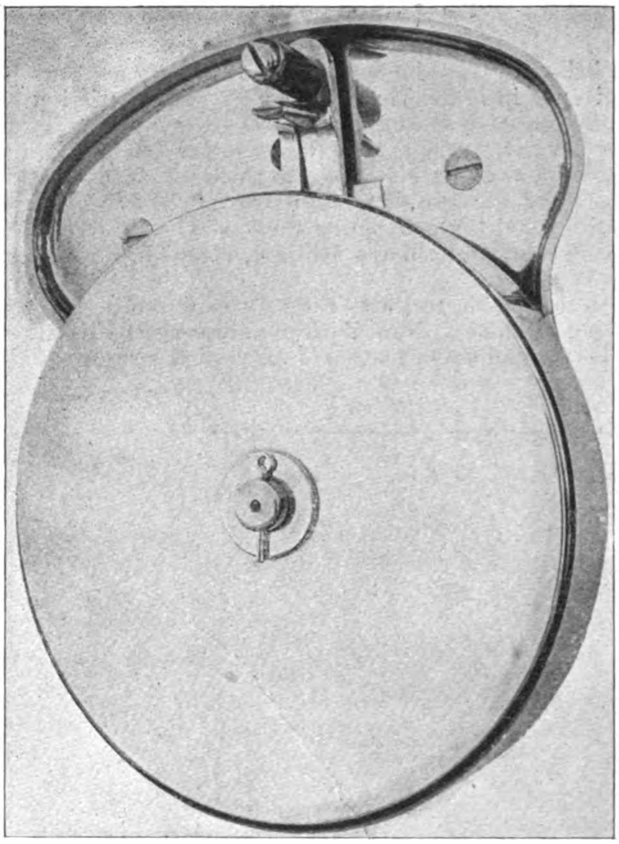

Fig. 9.—Car Switch, Sprague-Pratt Elevator.

an exceedingly low rate of depreciation on the ball nut and screw.

It is moreover evident that if the screw should become free to revolve unchecked by motor or brake, a most improbable conception under normal conditions, the weight of the car would not cause the screw to revolve at such a speed as would be dangerous to life. Then, too, there is the rubber buffer at the lower end of screw to cushion the end of such a run, as already described.

The use of the buffer, as well as the frictionless character of the nut have recently been most effectively illustrated by a very practical test on a large elevator car. In a recently erected plant where passengers were being carried at the same time work was going on on the machinery, on account of the absence of a limit stop three safeties of the machine were one after another thrown out of operation, the current supply was cut off, the locking strap was held back from the brake wheel, and a heavy car, starting from the fifth story of the building, was allowed to run absolutely free without a check of any kind or character except that which might be given by the increased friction of the balls in the operative nut. It quickly attained a speed of about 800 feet a minute, the screw going at 1,200; it then apparently ceased to accelerate, but at this speed the cross-head came against the buffer nut, compressed it, and in a space of about 18 inches in the travel of the car it was brought to a stop within six inches of its normal stopping place without breaking any part of the cables or fastenings and with absolutely no injury to the car and no shock to the passengers. Had a similar runaway occurred on a hydraulic machine the probabilities are that the car would have been smashed to pieces. No more severe test could probably be made upon this safety than the one instanced.

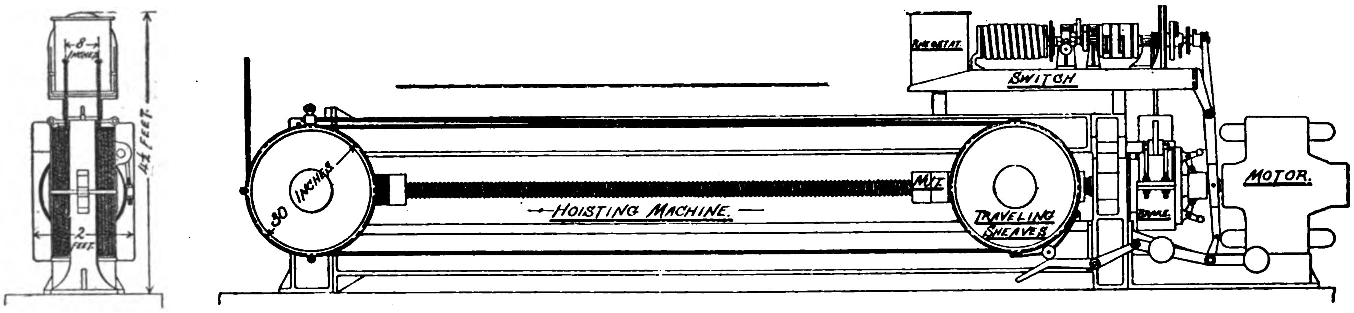

Fig. 10.—Architect's Diagram, Sprague-Pratt Elevator.

All other parts of this elevator are built on the same factor of safety as the screw.

Assuming that the car is perfectly safe for any load that it will be called upon to carry, it only remains to establish an absolutely safe connection between the hoisting machine and the car. Experience has shown that owing to the size and number of hoisting ropes used on passenger elevators, and the care that is taken of them, there has never been an accident due to the actual breaking (other than at fastenings) of the ropes on passenger elevators. This statement has been affirmed by Thomas E. Brown, consulting engineer of Otis Bros. & Company, and by letters from the leading elevator companies to the wire rope makers of whom they buy their ropes.

Ropes, however, have been known to pull out, or break away from their fastenings. This, therefore, is the last point necessary to establish the fact that this elevator is absolutely safe.

The rope fasteners used on this elevator consist of a solid body of metal which has a double spiral groove; the rope enters this groove by being passed through a loop in one end, wound twice in the groove, passed through a loop in the other end, returned in the other groove in spiral convolutions between the first winding and out through the loop in the first end. This engages about three feet of the rope, instead of about three inches which other rope fasteners hold. There is but one way that a rope can be put in this fastening, and it will hold almost any size rope equally well. Tested in Fairbank's testing scales, it took 10,500 lbs. to break a five-eighths inch iron wire rope, which gives this rope a higher rating than the makers give it in their catalogues. The engineer in charge of these scales stated that other rope fasteners usually break the rope at from one-half to three-fourths of the rated strength.

The increased safety factor in the Sprague-Pratt electric elevator is therefore clear. Although approved safeties will be used on every car built by this company, there is only the remotest liability that they will ever be called upon to work. The safety of an elevator should be from the point where the ropes are attached to the car to the point where the hoisting power is applied, assuming of course a perfectly safe car.

VIII.

Contrary to general assumption no elevator is safe which has to depend alone upon the car safeties, no matter how operated.

Car safeties may be divided into two classes, one being that in which the wedges are operated by the breaking of one or more of the hoisting ropes, the other being that in which they are thrown into action when the car accelerates its speed, whether hoisting or lowering, above a certain determined rate. This last is called a centrifugal safety, and may be operated by a centrifugal governor on the car put into play by a rope running the length of the hoistway, or by a centrifugal governor on the overhead beams.

The difficulty with the first car safety is that if for any reason the car runs too fast by any disarrangement of the machinery but without breaking of the hoisting rope the safeties are not thrown in operation, and the difficulty with the latter is that it may be thrown into operation when not desired, and on account of the annoyance of this the adjustment of the safeties is often changed so that they will not be thrown into operation except when there is a great increase of the normal speed. For example, it is practically impossible to stop a rapidly moving car by wedges on wooden guides without so cutting them that it takes not only some time to release the car, but the guides are so badly damaged that a piece has to be cut out and a new one put in. What is the result? Suppose a car should have a normal maximum speed of 350 feet per minute, and the centrifugals should operate when the speed, on account of an extra heavy load, is increased 10 or 20 per cent. On account of the difficulties with the guides, the engineer in charge will change the adjustment so that the wedges will not be thrown into operation until the car is running at, say, 600 feet a minute, that is, long after the allowed excess of speed has been reached. Since the momentum increases with the square of the velocity it is a much more difficult matter to arrest the movement of the car and even if arrested the stop is by no means a pleasant one.

Another difficulty with the centrifugal governor, whether on the car or on the overhead sheave beams, is that on account of its apparent inaccessibility it is often neglected, becomes gummed up, and when needed is found to be inoperative.

Despite the difficulties which have arisen with this kind of centrifugal governor the high-speed car should have something of the kind.

But it should be a governor which is always in order, which can be thrown into operation with only a reasonable excess of speed over normal, and it should be readily accesible. This by the very nature of things can only be the case when the centrifugal governor forms a part of the operating machinery and is not dependent upon the ropes attached either to the car or the counterweight. The safeties operated by these elements should be brought into play only in case the normal safeties attached to the machine fail to operate. Hence in this electric elevator, no matter what car safeties are used, there is a centrifugal safety depending upon the speed of the driving screw which is made operative at any determined excess of speed, and when operative stops the car by checking the hoisting ropes.

Such a centrifugal is under the constant supervision of the engineer, it is always ready for operation, and if there has been no accident, but simply an increase of speed above that for which it is set, it can be instantly restored by the controlling switch and leaves the car free for operation, acting again promptly in case of any undue acceleration. The result is that even on short runs the centrifugal safety on this machine can be thrown into repeated operation without shock or jar and the car immediately set in operation again. This is an absolute impossibility with a hydraulic elevator, which has only such a safety on the car itself.

IX.

Not the least important consideration in replacing the hydraulic by this elevator is the

Economy of Space.—The Sprague-Pratt express elevator when supplied from a central station occupies only from one-tenth to one-third the space occupied by a hydraulic plant of equal capacity.

This fact has been established by strict comparison with diagrams showing the actual measurements of the space occupied by several representative modern plants of equal capacity now in operation in New York City, and put in by such well-known makers as Whittier of Boston, Crane of Chicago, and Otis of New York.

One very great advantage of the electric elevator is that it can be placed wherever required by the architect, either in the basement when it forms a small part of the total operative machinery in the building, or at some intermediate place, or upon the roof. This latter seems, and is, a radical departure from existing elevator practice, but it is undoubtedly going to become a well-accepted practice, especially where there are a nest of elevators operated and where the basement space is more valuable than that which would be occupied by the machine on the roof.

It is manifestly impossible to put a hydraulic machine on the top of a building, for of the three systems now generally adopted the tank system on the roof would have to be abandoned and either a direct system of pumping or a compression tank used. If the pump is in the basement, then the water would have to be pumped against the additional head due to the height of the building, and if on the roof the steam would have to be carried to it. Both plans are impracticable.

Any one wishing to estimate the space that this elevator would save in his own building, may, after measuring his hydraulic plant, or plans for a proposed hydraulic plant, as the case may be, estimate the space that the elevator would occupy, as follows: Measure the distance in feet that the car travels, divide it by the number of multiplying sheaves on the crosshead, and to that add 13 feet. This gives the length of the elevator machinery over all. Allow 2 feet for its width the entire length and 3 feet 6 inches for its height. This gives approximately the space required for this elevator. It can be located anywhere that it is possible to lead the ropes from it to the car over proper sheaves.

A vertical cylinder machine has often been preferred in order to save basement space; in this connection it is important to state that this elevator, although resembling the horizontal hydraulic machine, occupies less space than the smallest possible pumping plant alone of the vertical cylinder machine of equal capacity. One material advantage obtained is the saving of the space occupied in the shaft way by the cylinders and sheaves all the way up the building, and also to confine all such machinery and apparatus to a place where it can be most effectively cared for.

The value of the space saved varies with the conditions of the building. For instance, where safe deposit vaults occupy basement space the first cost of this elevator might be paid for in one year's rentals of the space saved.

In an office building the absence of the noise, odor and heat of a steam pumping plant, and the substitution of this elevator, leaving only a low-pressure boiler to heat the building in the winter, would make the basement habitable, and the space thus saved would accommodate one or more good offices.

It has in any case the indirect value of increased coal or other storage capacity and greater comfort in warm weather, when with this elevator no fires would be required.

X.

Realizing that in no electrical application need more care be taken than in the operation of electric elevators, in other words electric railways running on 100 per cent. grade, the utmost care and study has been given to this system before any public description of it has been permitted. No one could risk his reputation, nor the public its capital, unless the soundness of the principles involved and the perfect reliability of the machine were fully demonstrated. It was necessary not only to prove that there was a distinct gain in economy, a saving in operating expense for the same duty, and in the space occupied by the elevator, but its safety must be so far beyond question that come what may, either in the way of failure of current, breaking of some part of the mechanism, attainment of abnormal speeds, or gross negligence and carelessness on the part of the engineer, the safety of the people in the car must be assured. It is believed that this has been attained.

The work of the development of this machine has taken nearly four years. It embodies the labors of a number of people familiar with the questions involved. For a year there has been in operation on West 23d St., New York, the first of these machines, running about 250 feet per minute, and supplying freight and passenger service on both sides of the elevator for a five-story building. About every kind of accident or breakdown has been intentionally put into operation on this machine, and even almost vicious attempts made to wreck it, but as yet there has been no disastrous esult to record. It has even passed successfully through a fire. Having determined on this machine, all the essential elements, there has recently been put into the Grand Hotel, at 31st street and Broadway, a machine of similar type, but on an improved model, on more severe duty and under circumstances which are certainly not to be considered as experimental. This elevator has a double-decked car 6 feet square and about 16 feet high, weighing without the counter-weights about 2,300 lbs. It has a normal speed of about 250 feet a minute, and changes can be readily made to increase this speed to 450 feet per minute. It is now on duty 18 hours and will soon be on duty 24 hours a day the year around. There is no relief, because there is no other elevator in the building, and it affords the only way, except the stairways, of getting to the upper floors.

Following close upon the beginning of this operation the most important elevator contract at present signed in the city of New York has been awarded this system. This contract is for a nest of six high duty elevators in the Postal Telegraph building at Broadway and Murray street. This building is 14 stories high; the elevators, four of which are way, with a capacity of 325 feet per minute with a live load of 2,500 pounds, and two express having a capacity of 400 feet per minute with a load of 1,800 pounds, have a run of 165 feet, and the service will vary from 10 to 24 hours per day. Since the main offices and operating-rooms of the Postal Telegraph Company are on the upper floors, and the building has an annual rental of about $200,000 a year, this contract likewise prohibits experimental conditions. The elevator machinery will be in the basement, the two express machines, on account of the lack of space, being set crosswise on the way machines. This is the first of the larger contracts and as this article goes to press there are others which are crowding on.

Of course the manufacture of apparatus of this kind requires high class mechanics and the best class of machinery. From the standpoint of the manufacturer, the tools which form a part of the shop equipment now being gotten together for this work would prove interesting, as there is probably not in the United States an equipment of higher character, nor one better arranged for accurate, reliable and rapid output.

ELECTRIC COOKING AT OTTAWA, CAN.

Some of the work done at Ottawa, Can., lately with the Ahearn electric heaters and cookers has awakened considerable interest all over this country. These heaters, the invention of Mr. T. Ahearn, of the firm of Ahearn & Soper, have passed under the control of the Railway Equipment Company, of Chicago, and are to be vigorously introduced wherever the conditions are favorable. In Ottawa the cheap supply of current from the Chaudiere Falls has been an incentive to the use of electric heaters, but there are many places where the conditions of convenience and safety are such as to warrant their employment even with current at the ordinary city rates.

To illustrate what could be done, a dinner was given last August to 100 guests, at the Windsor Hotel, Ottawa, when a menu of several courses and some 30 dishes was provided. All the meats, including a 21-pound roast of beef and a 13-pound roast of veal, as well as three big turkeys, were cooked at the same time, and not half the oven space was occupied. The inside measurement of the oven used was four feet square, the ceiling being arched. There were two electric stoves in the oven, and the current consumed by the two was 43 amperes at 50 volts, or about 3 h. p.

At the Central Canada fair this month (October) a similar demonstration on a larger scale has been made by Mr. R. E. Jamieson, a local baker and confectioner of renown. We illustrate the exhibit. The oven was built of 16-inch walls on a stone foundation; the cooking space was four feet square; the ceiling was arched. Three stoves were placed below the floor, and were controlled by the switches shown on the top of the oven. The floor of the oven was made of iron gratings with a 6-inch air space beneath the grating for the heat to circulate under the bake-pans. At the rear end (not shown in cut) was placed a peep hole 16 inches long by 6 inches high, of three thicknesses of plate glass slightly separated to prevent induction of heat from within, to allow visitors to inspect the process of baking, the interior of oven being whitewashed and lighted with incandescent lamps. The current used was supplied by two 40-light Westinghouse converters, the quantity consumed by each stove being 20 amperes at 50 volts. Ordinarily two stoves are sufficient for an oven of this size, but a third was added to this exhibition outfit to compensate for the inordinate opening of the oven door.

No fewer than 12 pans were going at a time, people waiting their turn in crowds. The electric buns were sold at the rate of 25 cents apiece, a price that must have gladdened the thrifty soul of Mr. Jamieson and should be a great inducement to other bakers in other cities to avail themselves of like opportunities. "Went off like hot cakes" now reads in Ottawa "went off like electric cakes."

The oven was equipped with pyrometer, turn-off switches, clock, etc., and was the attraction at the fair. Mr. Ahearn was awarded a special gold medal for the display, which included, also, house heaters, coffee boilers, and special heaters for the restaurant in the main building for cooking food.

The Ahearn apparatus, so far as shown, is generally cylindrical in form, consisting of inner and outer tubes of iron, upon which resistance coils of German silver wire, protected by asbestos, are wound. Vacant spaces are filled in by powdered whiting.

Baking Cakes by Electricity at the Ottawa Fair.

PRIZE FOR A MICROPHONE.

Nature, of London, announces that Baron Léon de Lenval, of Nice, offers a prize of 3,000 francs to the inventor of the best application of the principles of the microphone in the construction of a portable apparatus for the improvement of hearing in deaf persons. Instruments for competition should be sent to Prof. Adam Politzer, or Prof. Victor von Lane, Vienna, before December 31, 1892. The prize will be awarded at the Fifth International Otological Congress at Florence, in September, 1893. If no instrument is judged worthy of the prize, the jury reserves the right of announcing another competition, unless Baron Lenval decides to dispose of the prize otherwise. The following are the members of the jury: Prof. Adam Politzer (president), and Prof. Victor von Lang, Vienna; Dr. Benni, Warsaw; Dr. Gelli, Paris; Prof. Urban Pritchard, London; Prof. St. John Roosa, New York; Prof. Grazzi, Florence.

INSURANCE INSPECTION IN THE MIDDLE STATES.

Attention is drawn to the notice on advertising page xii, of this issue, in which electrical contractors doing business in the Middle States are requested to correspond with the secretary of the Underwriters' Association, 316 Walnut street, Philadelphia, with regard to installations in that territory.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 203 *Broadway, New York City.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can :entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XIV. NEW YORK, NOVEMBER 2, 1892. No. 285.

The application of science to the arts and industries is to but one purpose—to get the greatest return for a given amount expended.—David Brooks.

THE FARMER AS A RAILROAD KING.

IT is worthy of note that a convention was held recently in Chicago to form an association which should improve the country roads of America. The object is one that must win universal applause; the means to be adopted, and the exact nature of the end sought, remain fit topics of discussion and criticism. There can be no question that, on the whole, country roads are in a bad condition, and by "country roads," we mean highways as well as byways. Just how wretched they are no one realizes more keenly than the bicyclist, enthusiastic over the idea of running his wheel from one great city to another, for his experience is not local like that of the farmer, but takes in a good many counties and more than one State. Here and there, the roads are hard and smooth, affording easy travel; but by far the largest number are soft or rough, and transportation over them is painful and expensive. It is estimated that, as a result, the farmers of the United States are keeping 2,000,000 horses more than would be required if the roads were good; and the loss to the farmers is put at $500,000,000 annually, due to their upkeep of the horses, wear and tear, and sacrifice of produce.

To replace the bad roads by good, it is proposed to raise money on issues of county bonds. That being the case, we would like to suggest that the best thing the farmers can do is to go in heartily for electric roads. We may be wrong, but our conviction has long been that in the resort to electricity lies a solution of the country road problem, so far as the transportation of produce is concerned. What is needed is simply to get produce quickly and cheaply to the nearest point of shipping or of consumption, and there can be no quicker or cheaper way than of running it over a track. In fact the highway without a track on it will soon be looked upon as a relic of barbarism, not worthy of being considered as a part of the system by which civilization holds together.

A curious instance of the tendency in this direction was afforded the other day by a rancher at Farmington, Cal. He has a big ranch, and during the past season did all his ploughing with an engine, running it night and day with three shifts of men. After the grain was threshed he had 30,000 sacks of grain to haul to the railroad for shipment to Stockton, a distance of seventeen miles, at an expense of $1.10 per ton. Instead of loading up his wagons, hauling to the station, and unloading into cars, he simply hitched nine wagons to his engine, loaded up in the field, and hauled along the road to Stockton, requiring five hours for the trip, the only expense of hauling the forty-two tons being the wages of three men and the coal used. Now, what was done in this way with a ponderous traction engine on a soft dirt road, would be infinitely easier with a light electric trolley system, and ought to be a good deal cheaper.

The construction of these country trolley roads would not be expensive, and their tracks would afford smooth travel for other than the trolley motor and the trolley freight trucks. The supply of motive power is not a difficult problem. To-day a large portion of the American farming area is within touch of the 500 towns and cities that now enjoy trolley traction. Elsewhere a large portion lies adjacent to cheap coal or cheap water power. And even where the supply of current would appear difficult, the enhanced value given the farm lands that could ship away their produce promptly, would come in to meet the exigencies of the case. Moreover, the very ease in handling delicate products quickly would invite to a diversification of crops of greater value.

It might be said that a steam road would do all that a trolley road could do. That is not true, whether in regard to the cost of the installation, the simplicity of the apparatus, or the expense of operation. On the contrary, the main lines of steam railroad have been waiting for just such feeders as these trolley roads will prove to be, while many of the shorter steam railroads that have already absorbed all the old functions of the highway would be more profitably run, if they were at once converted into electric roads. If anybody thinks we are wrong about this, we hope they will quote it against us five years hence. Meanwhile the signs of the times seem to us such that, on the basis of mileage of electric track operated, we expect to see the farmer a railroad king before this decade runs out.

THE IMPOSTOR SHOULD BE NAMED.

IN an able paper prepared for the Fire Underwriters of the Pacific, Mr. Geo. P. Low, the electrical inspector of the Pacific Insurance Union, mentions the case of a theatre wired for incandescent lamps, where Grimshaw was specified. During his absence, the work was done, and on his return he found all the wire at the outlets and open portions to be all right. On a written assurance that the work met requirements, it was accepted. Some time after, the theatre underwent reconstruction, when it was found that of the 9,757 feet of wire taken from the building, only 2,520 feet was Grimshaw. The remainder was ordinary weatherproof, a grade that is condemned for concealed work. The evidence of guilt was ample, for the wire showed that short pieces of Grimshaw were spliced on at the terminals and outlets.

Such a case is a disgrace, and yet Mr. Low says that this impostor is still in active business. Something should be done to expose a man who thus imperils life and property and brings contempt on an honorable profession. If Mr. Low will send us the man's name, we shall feel inclined to publish it in big black type.

A DEPARTURE IN ALTERNATING CURRENT PRACTICE.

The detailed description which we gave in our last issue of the new 500 h. p. direct connected Westinghouse alternator now being installed in the station of the Narragansett Electric Light Co., at Providence, R. I., deserves more than passing notice, as it marks a distinct departure in two directions in the alternating current practice in this country. In the first place the alternator constitutes practically the first large machine of this type connected directly to the shaft of the driving engine, a practice which has just been inaugurated with continuous current dynamos in this country, but which is no novelty in England or Europe. The connecting of the alternator to a slow speed engine naturally called for a modification in frequency of alternations, and in this respect, also, a wide departure has been made from the practice heretofore embodied in the Westinghouse apparatus. The reduction from 133 periods per second to 60, will bring about important improvements in the alternating current field, as the reduced number of alternations while well adapted to lighting is especially applicable to the operation of alternate current motors, whose self-induction will thereby be largely diminished.

LAMP PROSPECTS.

Curiosity and interest in electric circles are perhaps pretty evenly divided between expectations touching the policy of the General Electric Company under the recent decision in the Edison lamp case and respecting the promised early advent to the market of the new Westinghouse lamp. General attention has been drawn to the announcements of the Westinghouse Company that their lamp does not infringe the Edison patent, that its price will be so low as to be a surprise to all users, and that their price list will be forthcoming in November. Under a large reduction in existing prices of lamps and with the ability on the part of consumers to have the filaments replaced, preserving the remaining portions of the lamp, the cost of lamp supply and renewal—a very considerable portion of the running expense of a station—should be greatly reduced. We have heard the saving in this regard by the Westinghouse Company in lighting the World's Fair for six months estimated as high as $50,000. A minor point of interest in connection with a removable carbon is that it may stimulate the use and production of ornamental bulbs since they can be used for an indefinite period instead of being destroyed with the carbons.

ELECTRIC MOTORS FOR THE FARM.

In the West steam power is used by the farmers to a large extent for threshing grain, and in Manitoba several disastrous fires have been caused by sparks from this source. The *Winnipeg Commercial*, in a recent editorial drawing attention to this, says that every farmer who employs steam threshing appliances runs a serious risk of being burned out, and as a remedy advocates the substitution of electric power, for then the engine and boiler for operating the generator could be placed at a safe distance from combustible material and the power transmitted to where the threshing machinery was located. We commend this idea to the attention of Prof. G. D. Shepardson, at Minneapolis, and Prof. R. B. Owens, at Lincoln, Neb. The question is one that has peculiar and special interest for the States in which they officially represent electrical engineering.

THE SPRAGUE-PRATT ELEVATOR SYSTEM.

After all, it is but natural that Mr. Frank J. Sprague, seeking fresh fields and victories new, should exchange the comparatively easy problems of street railway traction for those of elevator service, which represent an electric road with a 100 per cent. gradient. The result of his work in the perfection of electric elevators is stated in this issue by Mr. Sprague himself and his able co-inventor, Mr. Pratt, who has long made a special study of elevator operation. The system adopted by them is that of the screw and nut, as fully explained in their most interesting article. Whatever Mr. Sprague says and does is regarded as worthy of most serious attention, and it would appear that the Sprague-Pratt elevator as here described marks a not less important advance than that which was made on the steep red hillsides of Richmond.

"Last Call to Dinner"?

A circular, received a few days ago, offers perhaps the last opportunity of achieving fortune through the investment of a few dollars in the stock of the "Pennock Battery Electric Light and Improvement Company." The par value of the shares is $1. They are offered now at a premium of only 900 per cent.—the price is $10—certainly dirt cheap in view of the $30,000,000 to $50,000,000, expected to flow into the treasury from sales of State rights.

Of course the General Electric, Westinghouse and other companies, will not last long under competition with the Pennock System—for who will buy "the old-fashioned dynamo system" when the Pennock people will light you (brilliantly) 1,000 electric lamps cheaper than the old fogies who continue to make dynamos can light (faintly) 100 lamps? There have been primary battery schemes a-many, but heretofore none so glowing as Mr. Geo. B. Pennock's.

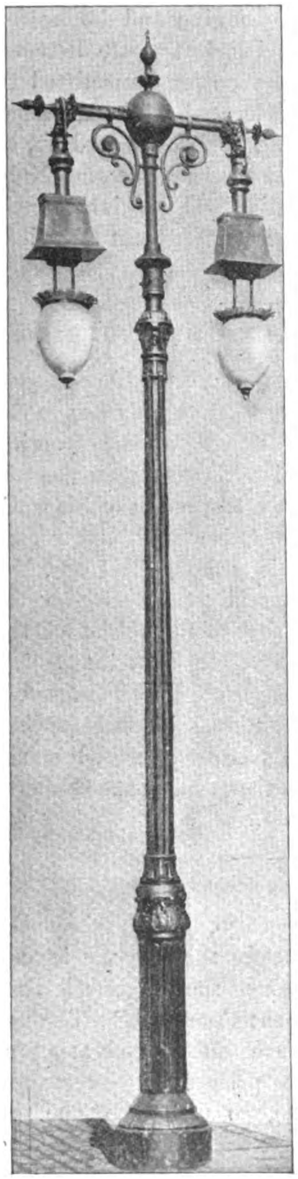
The Cheapness of Platinum.

It is a curious fact, in connection with the present discussion of incandescent lamp manufacture, that platinum has not been so cheap as it is to-day since the very first production of the incandescent lamp. This is at once significant and encouraging.

THE LIGHTING OF FIFTH AVENUE, NEW YORK.

BY

Jos. Wetzler.



The New Arc Lamps on Fifth Avenue.

HE Columbus celebration, while it called into existence numerous temporary electric lighting effects of great beauty, also witnessed the inauguration of a method of street lighting which, we are not mistaken in asserting, embodies elements that will make it a favorite one wherever it can be applied. We refer to the illumination of Fifth Ave. in New York by arc lamps, taking current from the Edison low-tension street mains, and the method employed deserves more than passing consideration.

We may premise here that shortly after arc lighting by the series system was introduced in New York, Fifth avenue was illuminated by it, and continued to be so up to the time that the crusade against overhead wires culminated in their removal. When the series arc-lighting companies were compelled to go underground the heavy rental of the conduits made the lighting of Fifth avenue unprofitable, as very few private arc lights are used on that street. High tension conduits were laid only between 23d and 42d streets, and these were not utilized for street lighting. The upper part of the thoroughfare returned to the gloom of gas, and the lower part still had overhead wires.

Upon the approach of the Columbus celebration the authorities were petitioned to relieve the upper portion from its gloom, and the height of the "floats" prepared for the night pageant required the removal of the overhead wires. The Mayor was averse to the re-opening of the pavement, and the engineer of the Board of Electrical Control was directed to ask the Edison Company if it could not provide street lighting from its mains. The conditions absolutely forbade the stringing of any overhead wire, or the use of an underground bridging conductor between the lamps on successive posts. The ordinary method of connecting low-tension arc lights in series could not therefore be utilized, but the problem here presented was solved in a very neat manner by Mr. R. R. Bowker, first vice-president of the Edison Electric Illuminating Co., and the lamps have been in nightly operation since the Columbus celebration, extending from Fourth up to Fifty-eighth streets.

The essential feature of the new system is the employment, instead of a single arc lamp, of a pair of arc lamps on one post, each lamp taking five amperes at the usual arc-lamp voltage, approximating 50 volts. By this arrangement practically the same amount of energy is used as in the single arc lamp on a high tension in series circuit, but it has the double advantage of permitting connection with the Edison mains through the ordinary house service, without running any special circuit or connecting wire from post to post, and of giving a more effective light, of better diffusion, so that absolutely no shadows are cast, thus avoiding a chief objection to the ordinary street arc lighting.

The accompanying engraving shows one of the ornamental posts employed. It is made in three parts, the base, the shaft and the arm section. The resistance, instead of being placed in the hoods of the lamps, is provided for within the base, and the lamps are raised and lowered from within the shaft, access being had by a door which opens in the base, the key of which is carried by the trimmer. The lamps are fed by a sliding contact in the hood, so that when the lamps are lowered they are automatically cut off from the current and are absolutely dead. No climbing of poles is required by the trimmer, and there is no chance of obtaining even a low-tension shock when the lamps are trimmed. The current, as remarked above, is supplied from the Edison mains by the ordinary house-service method, the supply wires running through the gas pipe which forms the centre part of the shaft. The hoods and the posts are of a highly ornamental pattern, and the type of lamp adopted is a new arc lamp developed by the General Incandescent Arc Light Co., of which Mr. S. Bergmann is president.

The new system, which will be patented, is unlike any thus far employed, either in this country or abroad, the Unter den Linden lighting in Berlin, to which it has been compared, being quite dissimilar. There, single arc-lights, which have to be connected "in series" with another light beyond by an overhead or underground special wire, are suspended over the central promenade from uprights on either side, these being supplemented by side lights along the house fronts. The device of placing two arc lights together on one post with self-contained resistance, though simple enough, does not seem to have been before developed; and it makes possible for the first time a street-lighting system by which individual lamp-posts can be lighted from low-tension mains by the ordinary service connection at any place along a street where there are low-tension mains, without connection with other posts. All the features of the new system are not yet developed, as it was the special desire of the Mayor and the city authorities that the whole of Fifth avenue should be lighted by the new system before the Columbus celebration, which left no time for experimental work.

EARTH TROUBLES FROM TROLLEY SYSTEMS.

BY P. HOLCOMB.

SOON after the trolley appeared in Atlanta earth troubles were felt by the telephone people. The telegraph wire chiefs next noticed them while testing for conductivity. Now the system has grown and the leakage has increased till one can see the effect on a short-distance quad. The current is always of zinc polarity, lasts about half a minute and occurs at two-minute intervals during the middle of the day. A No. 6 wire from Atlanta to Macon, grounded at both ends works readily by ordinary Morse relay. Also a No. 12 copper to Charlotte, N. C., 267 miles. Any 1,000 ohm circuit grounded at both ends shows a current varying between 2 to 20 milliamperes. The Postal Co. also finds the same leak on its wires. Various grounds have been tried in different parts of the city and an insulated wire run to the bottom of a well, but no better results have been obtained. An experimental ground made at the river, however, eight miles distant, shows no escape.

INSULATED ELECTRIC CONDUCTORS.[1]—XII.

BY

James Brewster Williams M.E.

The expression "painted wires" is generally used to designate insulated conductors, the dielectrics of which are formed of cotton fibre saturated with paint. To this class belong fireproof and some weatherproof wires. These last named, however, are used chiefly for convenience of description, since all fireproof wires should be weatherproof as well, but weatherproof wires are not always fireproof.

Fireproof Wires.—The underwriter's wire is an example of this class. The principal reason for their manufacture was to provide wires with coverings which would not allow fire to run along them when from any cause such coverings might become ignited; in other words, to produce wires having uninflammable dielectrics. Insulation, if judged by results, appeared to be a secondary matter. The manufacture of wires with dielectrics which are at the same time fireproof and highly insulating is almost an impossibility for the reason that the material which renders the dielectrics noncombustible, possesses, as a rule, poor insulating qualities. Further, fireproof dielectrics, *i. e.*, those which are not soon injured by fire and will not burn with a flame, are quite brittle and crack when bent, thus allowing moisture to have free access to the conductors.

Even when asbestos, which is one of the best incombustible fibrous materials, is used as the body of the covering, there must be some kind of a filling for the interstices of the fibre and this filling material, to be fireproof, must have a large quantity of incombustible matter incorporated with it or be composed entirely of such matter. In either case the filling will have poor insulation or will crack when the wires are bent.

Cotton may be rendered uninflammable—although it will char—by soaking it in a solution of pure tungstate of sodium; but the presence of the sodium salt in the cotton will cause the specific resistance of this prepared fibre to be much lower than that of clean, dry cotton. Besides, the salt will readily absorb moisture when exposed to air. If oil is used as the vehicle for the fireproof material to fill the interstices of any fibrous covering, whether this material be powdered silica, mica, asbestos, or other mineral substance, the oil itself will burn unless it has a large quantity of some fireproofing salt mixed with it.

If asphaltum, which contains much petroleum or a flexible petroleum residue, is used for a filling it will require several times its weight of tungstate of sodium to be added to it to render it uninflammable; but the addition of the salt virtually forms a new composition which is neither flexible nor anhygroscopic. In fact, all substances and compositions, such as oils, resinous bodies, rubber, etc, which possess good insulating properties, require the addition of so much foreign material to fit them for use in fireproof dielectrics that flexibility, one of the essentials of any material for use with fibrous coverings, is almost, if not entirely destroyed.

Almost any dielectric having fibre for its basis will resist fire better if the dielectric is made compact and solid around the wire by means of heavy pressure.

It is to be understood that by a fireproof wire is meant one, the entire covering of which is formed of the same insulating materials, and that the covering should be moisture-proof. An absolutely fireproof covering could be formed of asbestos fibre alone but unless the spaces between the fibres were filled with moisture-proof insulating material such a covering would, except in very dry weather, readily admit moisture to the conductor and a current of high voltage would escape through the covering to any bodies connected with the earth with which the covering might come in contact. Almost any insulating covering can be so protected that it will not burn with a flame by tightly and completely enveloping it with asbestos fibre or other incombustible sheath.

The manufacture of fireproof wires will be understood from a description of that of the weatherproof wires, so that the manufacture of the former need not be described here.

---

EMPLOYEES' MEETINGS AT QUEEN & CO.'S LABORATORY.

BY

Percival A. Mitchell

Among the many novel features of the laboratory of Queen & Co., at Ardmore, Pa., is one lately introduced by the superintendent, Mr. Elmer G. Willyoung, which promises to be an instructive success. The idea is to hold at the laboratory, in the evenings, a series of bi-weekly meetings which the employees are invited to attend, and at which all subjects of interest in the electrical field are brought up for discussion.

Those who attend the meetings are divided into committees, whose duty it is to read up the various electrical periodicals, with which the laboratory is well supplied, and to report all articles and points of interest; even the French and German magazines are translated for the benefit of those who would otherwise be unaware of the progress of electrical science across the ocean.

Progress and development of and interesting points concerning work being carried on in the several departments of the laboratory are reported, questions are freely proposed, and no subject is dropped until a satisfactory explanation has been obtained and thoroughly understood by all those present. The meetings are held in the office of the laboratory on alternate Monday evenings. In the room is the library of electrical reference books and periodicals, and a large blackboard with both white and colored crayons is provided for the purpose of graphically presenting new ideas and also for illustrating the communications which are read. At the meeting, held Monday evening, October 17, Mr. Nelson H. Genung commenced a series of interesting talks on the theory of magnetism.

The main object in view is mutual improvement, and the development and perfection of new ideas, and if the present interest shown by the employees continues, there is no reason why it should not be achieved.

BRITISH POSTAL TELEGRAPH FIGURES.

During the financial year 1891-92 over 57,000,000 ordinary inland telegrams were transmitted; an increase of nearly 6 per cent. on the number for the previous twelve months. The annual value of each telegram dispatched has, however, come down from 7.87 to 7.77d, the total receipts from inland telegrams for 1891-92 being £1,848,974. The total number of telegrams, of all sorts, which were dispatched last year amounted to nearly 70,000,000, and brought in two and a quarter millions sterling. Taking telegrams of all sorts, the increase for the past year is only about 5 per cent. The receipts from the London-Paris Telephone for the first year of its existence have amounted to £4,616, and the number of conversations in April last was nearly double the number which took place in April, 1891.

Chicago Electrical Association.—The regular meeting was held on Tuesday, Oct. 25th, at 8 p. m., at the Atheneum Building, when a paper upon "Some Considerations upon Storage Batteries" was read by Mr. E. G. Hovey.

ELECTRIC RAILWAY DEPARTMENT.

JOINTLESS RAILS.[1]

BY

Townsend Wolcott.

The paper of Mr. A. J. Moxham on jointless rails, read at the meeting of the American Street Railway Association,[1] is very interesting, as confirming, and bringing before the public a fact, or supposed fact, of some antiquity. In Trautwine's Engineer's Pocket Book, edition of 1874, page 391, we find: "It is a remarkable fact, not satisfactorily accounted for, that when lengths of from 100 yards to some miles of rails have been perfectly welded or riveted together tightly and spiked to the ties as usual, no elongation or contraction by heat or cold could be detected."

This refers to the ordinary construction of steam roads, the rails being held in no way except by being spiked to the ties as usual. The above quotation is omitted from the later editions of Trautwine, as though the author had lost confidence in the authenticity of the alleged fact. Mr. Moxham's experiments, however, would seem to show the possibility of holding the track, and it remains to be shown by practice whether the additional difficulties which Mr. Moxham himself mentions, of laying and keeping in repair long stretches of jointless rails, are not very serious obstacles to their use.

DYNAMO DRIVING AND THE PERFORMANCE OF RAILWAY ENGINES.

BY

A L Hunt.

In the description of the new station of the Lowell and Suburban Street Railway Co., contained in the Engineer, of Oct. 12, I notice a statement that I do not think is quite correct. It is claimed by Mr. Shaw that the arrangement of generators is quite new, one belt driving two generators, both being mounted on the same bed-plate, etc. Now, some time in the fall of 1890, I had occasion to visit the power station of the Troy and Lansingburg Railway Co., at Lansingburg, N. Y., and saw there an arrangement of generators practically the same as used at Lowell. The engine was a "Greene," made by the Providence Steam Engine Co., and would indicate about 350 h. p., at 120 revolutions per minute, which was about the speed at which it was running. It was belted direct to two Edison railway generators, which were mounted upon a base plate common to both, with the pulley between them, and a flange coupling on each armature shaft, to disconnect, if necessary. Another generator was belted from the same engine, and stood a little ahead of the others, at one side. Of course the fact of there being flange-couplings instead of friction-clutches, in use, was somewhat of a detriment, at times, but those in charge were very well satisfied with the operation of the plant. Plans were being made at that time, for a larger station, to be built in the spring of 1891, and the generators were to have friction-clutches, but I cannot say, whether the station was ever built or not, as I have not been there since.

As an instance of what underloaded engines will do on a pinch, let me relate what took place at the Belt Line power station in Utica, N. Y., on the day that the "Masonic Home" cornerstone was laid, some time last fall. The crowd was the largest ever seen in this city, and the "Belt Line" carried something over 30,000 people during the day, at 5 and 10 cents a head. This was done on a consumption of about 8½ tons of mixed coal worth $1.90 a ton, while the amount used ordinarily was nearly 7 tons a day. This seems to me a pretty fair showing of what mistakes were made in designing power stations some time ago. This station is equipped with three cross-compound condensing, high-speed engines, that are rated at 200 h. p., with ¼ cut-off in the high pressure cylinder, which is supposed to be the most economical point. Two 60 K. W. generators were driven by each engine at the time of the performance alluded to above. Here is an instance where, in order to work the engines at anywhere near their economical load, the generator must be considerably over-loaded. This whole station, by the way, was supplied with steam from two 6 x 16 foot boilers, with natural draft.

THE NEW POWER HOUSE OF THE CENTRAL ELECTRIC RAILWAY CO., BALTIMORE, MD.

BY

A. K. McCay.

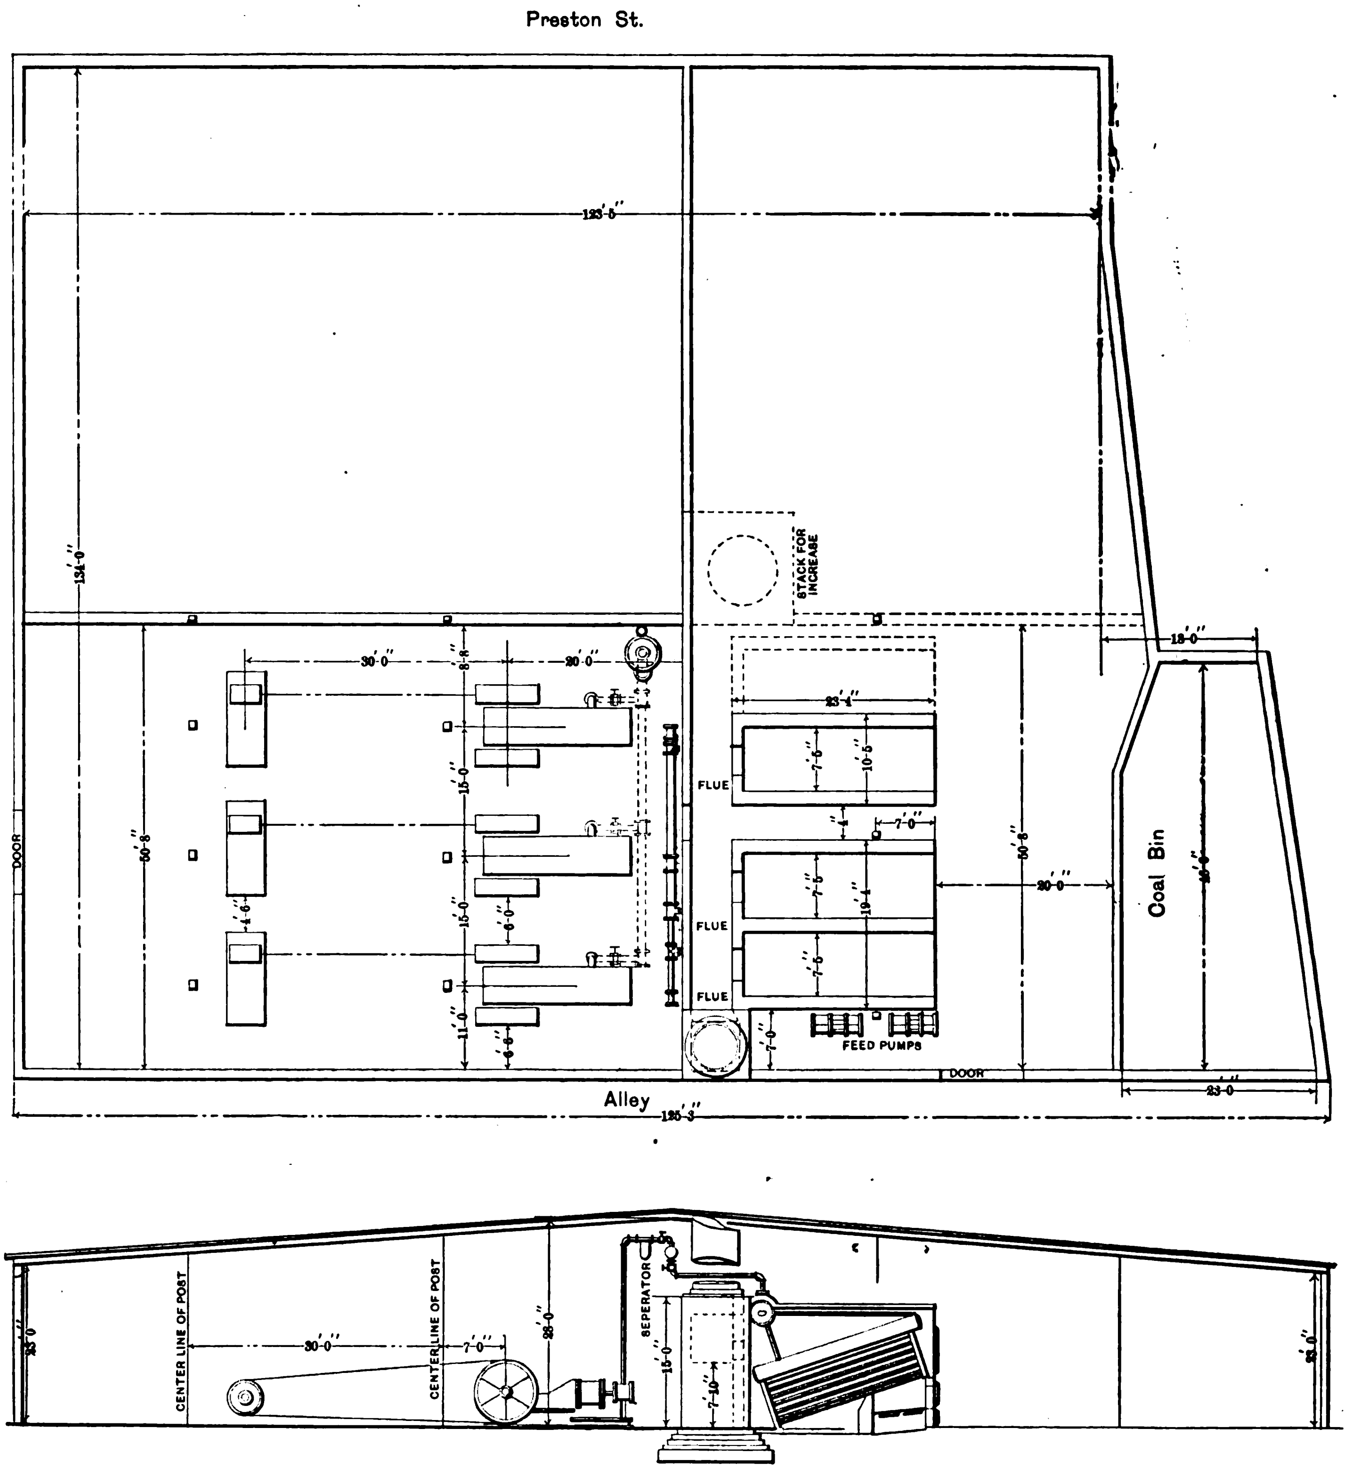
The Central Electric Railway Co. followed close on the heels of the Baltimore Traction Co. in signing a contract to convert their line from horse to electric traction. This line extends from the southeastern corner of the city to the northwestern, then running north for about a mile and a half through the older portion of the city; turning east it courses through the most fashionable and wealthiest part of the city for two miles. In its course from east and west it crosses nearly every other street car line in the city; then it turns north again and runs within two short blocks of Baltimore's main pleasure ground—Druid Hill Park. The total length of line is about six miles, and its success as a horse car line will, no doubt, be fully sustained as an electric line.

The arrangement of the station is shown in the accompanying plan and section, Figs. 1 and 2. It consists of three compound engines, made by McIntosh, Seymour & Co., of 250 h. p. each. These are belted to three multipolar compound Thomson-Houston generators. The switchboard is of slate, and is of handsome design and finish. The boilers are of the Campbell-Zell water-tube type. They are so arranged that two constitute a battery, while the remaining one will be used as a reserve. It is intended, should another boiler be added, that the odd one will be connected with the new one, forming two batteries. The normal capacity of the three is 675 h. p. The stack for these boilers is 6 feet 6 inches in diameter and 110 feet high. The masonry on which it stands is 15 feet high, making the stack 125 feet above the boiler-room floor.

---

[1] See The Electrical Engineer, Oct. 26, 1892.

The road will begin with twenty 16-foot Stephenson cars, mounted on McGuire trucks, and each equipped with two W. P. 50 Thomson-Houston motors, fitted with the new series parallel controller. The track work is of the most substantial kind. It consists of 80-lb. Johnson girder rail, spiked direct to chestnut ties. Tie-rods have been placed every 7½ feet, while the fish plates are 26 inches, bolted with six 1-inch bolts. The track is well laid, and shows careful and conscientious work by the contractors. The line work has been put in by Messrs. J. G. White & Co., of New York, and is of the most substantial order. Side construction with heavy span wires has been used throughout. The poles are of the hollow-pipe pattern, being built up of 6-inch, 5-inch and 4-inch pipe. They were made by Morris, Tasker & Co., of Newcastle, Del., and seem to stand the strain wonderfully well. My only criticism on the line work is that the span wires are tied directly into eye bolts passing through the pole-top, leaving only the bell and the wooden plug as an insulation against grounds. All poles on the straight runs weigh 750 lbs., while the curves are of 1,000 lbs. weight.



Figs. 1 and 2.—New Power House of the Central Electric Railway Co., Baltimore.

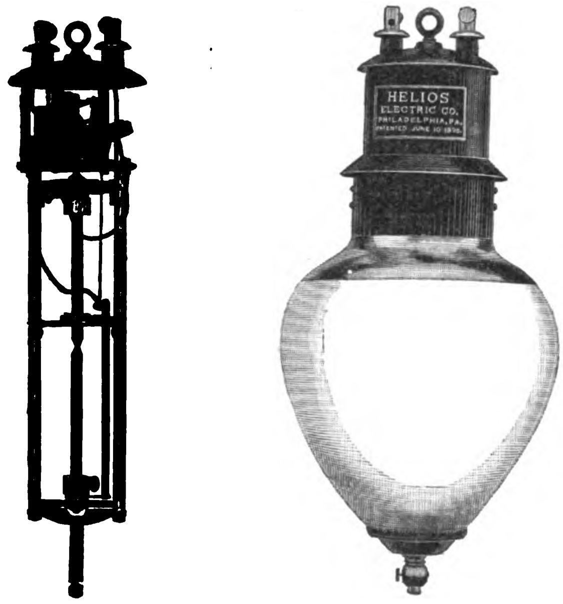
The consulting engineers of this road are Messrs. Blackwell and Murdoch, Mr. Blackwell having given his personal attention to the work, which is first class in every particular.

The Canadian General Electric Co.—Letters patent have been issued by the Dominion Government increasing the capital of this company from $1,000,000 to $2,000,000.

MISCELLANEOUS.

THE HELIOS ALTERNATING ARC LAMP.

NOTWITHSTANDING the large number of central stations that distribute alternating currents in the United States, it is a remarkable fact that but few arc lamps are now in operation, and this is the more strange, as the alternating current is especially adapted to long-distance lighting. For the past six years Mr. Carl Coerper, of Ehrenfeld, Cologne, Germany, has devoted his entire attention to the production of an alternating current arc lamp which should fill the requirements of a commercial lamp, and succeeded some two years ago in producing a lamp of which a large number are now in successful daily operation in Germany. The manufacture of this lamp has now been undertaken by the Helios Electric Company, of Philadelphia, which was organized specifically for this purpose, and the tests which we had occasion to witness leave little doubt that a large field will be open for the new product.



HELIOS
ELECTRIC CO.
PHILADELPHIA, PA.

FIGS. 1 AND 2.—HELIOS ALTERNATING ARC LAMP.

Our engraving, Fig. 1, shows the lamp mechanism exposed, and Fig. 2 the appearance of the lamp when burning. The construction and operation involve the most simple mechanism. As will be seen, the lower carbon holder is attached to a flexible cable which is carried over a pulley in the lamp mechanism, the other end being attached to the upper carbon holder. The result of this arrangement is that, as the lower carbon ascends the upper carbon descends, and in exactly the same ratio. The arc is thus fixed at a given point and remains stationary from the time the current is turned on until the carbons are consumed.

As is well known, the alternating arc forms a crater both in the upper and lower carbon, so that considerable light is emitted by the crater of the lower carbon, which is thrown upward, and thus generally wasted. To overcome this difficulty provision has been made in the Helios lamp by placing a white enameled reflector about 1½ inch above the arc, which throws down all the light emitted from the lower carbon, increasing the illuminating power 40 per cent., it is claimed.

The regulation is effected entirely by a single solenoid coil, the feed of the carbons being controlled by a lever which presses against the periphery of a friction wheel included in the releasing train. By this means a feed of $\frac{1}{1000}$ inch is made possible. The upper carbon holder is purposely made so as to slightly overbalance that of the lower carbon holder; the result is that the work of the solenoid coil and mechanism is restricted simply to the small weight representing the difference between the carbon holders. A free piston dash pot serves to steady the movement of the regulating mechanism.

The noise usually encountered in alternating current arc lamps has been entirely avoided, the lamp emitting no louder sound than the ordinary direct current arc lamp, and, we may add, burning with a steadiness which approaches closely to that of an incandescent lamp.

The design of the lamp, externally, is very artistic, the extreme length not exceeding 25½ inches.

These lamps are made of the following sizes: 300 watts, to produce 1,500 c. p.; 425 watts for 2,000 c. p They are connected in multiple arc and require only 28 volts, this having been found to be the most efficient pressure for alternating current. The Helios Company propose soon to supply a converter delivering 30 volts directly to the lamps.

ELECTRICITY AT THE DEDICATORY CEREMONIES IN CHICAGO.

A GLANCE at the electrical features displayed in Chicago during dedication week will not be without interest. Perhaps the most prominent was the great Schuckert search light built by Schuckert & Co., of Nuremberg, Germany, and which is installed upon the top of the Transportation Building at the World's Fair, and sheds its light over the city at night.

The current for running the search light was furnished by an Edison street railway generator, specially connected to furnish from 70 to 80 volts, and the current absorbed was about 150 amperes. This machine was employed for the purpose as the special one designed for use with the light was not ready.

It is to be regretted that there was not a night parade similar to the one in New York, so as to permit the liberal use of electrical floats and similar attractions. However, the electrical displays made by some of the large down-town stores and hotels were very creditable, especially so when it is considered that a large number of the electrical wiremen in the city were indulging in a strike, which was the reason that more electrical illuminations were not resorted to.

The display at the Auditorium Hotel, on Michigan avenue and Congress street was very handsome. From the tops of four tall pillars decorated with flags and buntings, strings of incandescent lamps were hung, and over the entrance were flags made of various colored lamps, to which a continual wave motion was given by a commutating arrangement, cutting the lights in and out. There was also a beautifully illuminated device comprising a cross, crown and initial letters. The current was furnished from the hotel isolated plant.

The "Leader," one of the large down-town dry-goods stores at the corner of State and Adams streets, made a pretty illumination. Incandescent lamps were freely used in the form of star-shaped shields and strings of hanging lamps.

Perhaps the most effective illumination was that made by Siegel, Cooper & Co,, the dry-goods merchants, who have one of the largest stores in the world on State street, between Van Buren and Congress streets. The arch over the entrance, surrounding the picture of the landing of Columbus, was beautifully outlined in incandescent lamps, and a large gilded eagle over the door was studded with lamps. On either sides were the dates 1492 and 1892 formed of lamps. The whole effect was strikingly beautiful. The *Inter-Ocean* had a very handsome electrical display on their building, corner Dearborn and Madison, of the stars and stripes and festoons of lamps; and the *Tribune* offices were also electrically illuminated.

A special temporary plant for lighting the Manufactures Building, in which the dedicatory ceremonies took place, was installed in the Machinery Hall. Eight arc dynamos, built by the Standard Electric Co., of Chicago, were run by Ball and Wood engines, steam being furnished from the regular battery of Babcock & Wilcox boilers, located there, and the current was furnished by these machines to arc lamps of Standard Co.'s manufacture, hung in groups of five in the Manufactures Building. In all, some five hundred additional arc lamps were used in lighting the buildings used during the ceremonies, and those in which the military were quartered and for illumination in the grounds. Those not supplied by current from the plant of Standard dynamos were operated from the regular temporary lighting installation in the grounds.

Displays of fireworks were held in Washington, Lincoln and Garfield Parks on the evening of Friday.

The whole pageant was one not to be easily forgotten by those who had the pleasure of witnessing it, and every one was surfeited with celebrations to their heart's content.

"THE ELECTRICAL ENGINEER" HOUSE WARMING.

A few months ago The Electrical Engineer moved into new quarters in the *Mail and Express* Building, Broadway and Fulton streets, New York City. These offices occupy the entire Fulton street wing and cover about 2,000 square feet. The building has been in a very backward state, and no electrical current was available until within the past week. Under these circumstances, the Engineer postponed its house warming until October 26, when in response to its invitation about 800 of its friends in this city came to pay their compliments and drink its health. Lunch was served by Cable in the reception room, from 12 to 3 p. m., and during that time all the various departments of electrical invention, commerce, manufacture, finance and study were represented by those who came to exchange greetings with the members of the editorial and business staff of the journal. The sentiments of friendship and esteem expressed towards The Electrical Engineer by so many well-wishers are the best return it could ask for its work in the past and the greatest incentive to effort in the future.

LETTERS TO THE EDITOR.

"NEITHER FISH, FLESH, FOWL, ETC."

In your review of "Recent Progress in Electric Railways," the matter for which I compiled for the publisher, your criticism is based largely on the fact that the compiled matter was limited almost entirely to that published in one journal. Permit me to say that such criticism is very unjust to the compiler in view of the fact that the preface distinctly states this limitation and makes no claims to include any but that one journal. It furthermore states that the compiler could not give the compiling the time he would have liked to give it. These statements ought to be sufficient to relieve the compiler from the blame which you direct to him in your criticism.

Owing to want of time and other circumstances beyond his control, the compiler was unfortunately not able to complete the compilation on the lines originally laid out and therefore had to limit himself to as much of the matter as was compiled at the time of publication, which part happened to be that from only one journal, the one with which the work was begun. But the fact that this fills a volume need not necessarily reflect discredit on the book, nor on the journal, nor on the compiler. Besides this, when an apology is made in the preface of a book for certain features which were unavoidable, it does not seem courteous to say the least, for a reviewer to disregard it completely.

Your unfavorable criticism to the effect that the book consists chiefly of quotations and abstracts, is on the face of it unjust, as that is the very thing that a compilation claims to be; it would have been unjust to the original authors not to have given them the credit for what was used of their matter.

The preface, moreover, is a publisher's preface and not an author's preface, which is evident from the omission of the compiler's name.

I might answer to a number of your other criticisms which I think are unjust, in which opinion I believe an unbiased mind would agree with me. Had all other journals but your own been used in the compilation you might have had reason for complaint, but the fact, as distinctly stated in the preface, that only one journal was used, an unfortunate limitation which was not premeditated, ought not to reflect on the compiler whose duties ceased with the compilation.

Carl Hering.

Philadelphia, Pa., Oct. 28, 1892.

[Mr. Hering's book says in so many words on its title page that it is a "summary of current periodical literature," and the preface uses the exact language we quoted from it. We said, and we repeat, that it is *not* a "summary of current periodical literature," but a bald "ad" for a single paper, whose name in it is thrust under one's eye at every possible and impossible opportunity. Our esteem for Mr. Hering as a clever journalistic colleague, as an able electrical engineer, as a writer of skill, and as a most amiable gentleman, makes us regret deeply that he could be seduced into such a performance as this wretched work, which is the queerest compound of fact, fiction and fol-de-rol that ever found its way into print as an electrical book. It is a great pity he did not keep his name off the title page as deliberately as he did off the preface, and so let the whole responsibility rest where it belongs.—Eds., E. E.]

THE COMPARATIVE EFFICIENCY OF THE COMMUTATED FIELD AND EXTERNAL RESISTANCE CONTROLLING RAILWAY SWITCHES.

Mr. Wellman's strictures on my articles entitled as above appear to be due to a misconception resulting from an oversight in his reading of it.

The second paragraph of my article begins thus: "For purposes of comparison we will assume that the resistance, turns in field, speed, current, etc., are the same in the two methods when all the external resistance is out of the circuit in the one and all the field coils are in parallel in the other." On this assumption all my arguments are based, and Mr. Wellman has not shown nor attempted to show that this assumption is unwarranted. Passing over the first paragraph of Mr. Wellman's article which merely contains the statement that I did not prove what I started out to prove, he passes on to give a résumé of my argument, and then says, "(The fact) that the resistance necessary to restore the speed (to a higher value) * * * * is less (in the commutated field method than with external resistance) is an argument in favor of external resistence; *i. e.*, we should use an intense field." That the field should be as intense as other considerations will allow is undoubtedly true, but Mr. Wellman has not shown, nor attempted to show, that the field will be any more intense in one method than in the other. And until he proves that the field can be made more intense with the external resistance than with the commutated field, it is not necessary to argue the point further. A little further down, the same statement is again made that the maximum field strength is obtained with external resistance.

Again, Mr. Wellman says: "This reasoning of Mr. Reid, also, only applies to decreasing the speed and how he would argue for on increasing speed, I dare not speculate on." By the assumption quoted above from my article, the two machines are exactly similar in every essential respect at their highest speed, and, therefore, since all the resistance is out of circuit in the one and all the field coils in parallel in the other, the speed cannot be increased by any change in either, and at full speed the efficiency of the two machines is the same by reason of the assumption I have made as a basis of comparison. Mr. Wellman's argument based on increase in speed would, therefore, assume the motors alike in every respect at some intermediate position of the switch, which is directly contrary to the basic assumption of my article. The last paragraph gives an indication of what Mr. Wellman took as a basis of comparison, since he says there that the current can never be the same in the two methods except at the first position of the switch, that is, when all the resistance is in circuit in the one and all the field coils in series in the other. If this statement, which is unsupported by argument, is true, then my argument falls to the ground and Mr. Wellman's arguments are good. In other words, the whole question between Mr. Wellman and myself rests on the propriety or impropriety of my fundamental assumption. Admitting that assumption, my argument, and therefore my conclusion, follows naturally. I will repeat what I said in concluding my article, that I did not attempt to decide which was the *best* method, but which was the most economical in the use of power.

Thorburn Reid.

Lynn, Mass.

THE OPERATION OF UNIPOLAR DYNAMOS.

In your issue of the 19th inst., Mr. W. E. Hyer rather severely criticises the quotations given by me from Prof. Silvanus Thompson's "Dynamo-Electric Machinery," and thinks it "unfair" to Prof. Thompson to quote his words in respect to one class of dynamos in condemning a modification of another distinct class."

The quotation to which Mr. Hyer so much objected was the following: "If the *coil* be moved by a motion of translation to another part of the uniform field, as many lines of force will be left behind as are gained in advancing from its first to its second position and there will be no current generated in the coil."

Let me say right here, that the quotation, as given, was not intended as an exhaustive explanation, but simply as a hint where such might be found. But as it seems that Mr. Hyer entirely misunderstood this quotation, it appears necessary to say what it really does mean, and at the same time place Prof. Thompson and myself in the right light in his estimation.

If a coil, with its plane normal to the lines of force, be moved across a magnetic field of uniform strength, electromotive forces will be produced in both sides of the ring, but both being of the same sign, they will evidently balance each other and no current will be generated. If the field is not uniform, then one part of the coil will cut more lines of force than the other, there will be a difference of potential between the two sides of the coil and a current will be generated.

It is not necessary to go into the different variations of this rule, and though Mr. Hyer considers it as "the A B C of the practical dynamo construction," I have found from personal experience, that most of the failures in the invention of unipolar dynamos have been caused by inattention to this rule, and in one case this happened to one of the leading electricians of this country.

There is not, as Mr. Hyer seems to think, a different law for different kinds of dynamo; the one cited holds good, no matter if the conductor is part of a unipolar, bipolar or multipolar dynamo. Neither is it the case with the ordinary bipolar and multipolar dynamo, that "the current is produced in the conductor by altering the number of lines of force that flow through it." On the contrary this non-uniformity in the number of lines of force cut, and the changing from one polarity to another is just the evils that inventors have attempted to avoid in the unipolar dynamo.

Mr. Balch in his article does not explain enough of the details of his apparatus; it is therefore difficult to point out just where the fault lies. The following lines from his article seemed to me, at the time, to indicate where the trouble might be, viz.: "If a soft iron tube is employed, a coil of wire, not shown, will have to be slipped over it to excite magnetism." If the tube is of some length, and the coil is placed near one end of it, the lines of force would not run through the air to the other end of the tube, but would return to the same close behind the coil. The conductor would therefore be cut by lines of force coming from opposite directions and there would be no current. Perhaps this might be somewhat obviated by an exterior shield for the return circuit. It is also a question if the coil would not have to revolve also, in order to make the conductor cut lines of force.

D. C. Reusch.

New York, Oct. 24, 1892.

SPARK LENGTH.

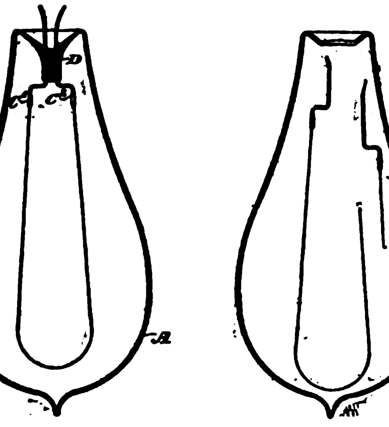
Two plane circular metallic discs are kept parallel to each other. One of the discs is fixed and absolutely insulated; the other, movable, and connected with the earth. If the movable disc is brought to within .08 of an inch of the fixed disc, a spark passes between them in air. What is the potential of the fixed disc just before the discharge?

Querist.

New York City, Oct. 27, 1892.

THE SMITH SEPARABLE INCANDESCENT LAMP.

Much attention has recently been devoted by inventors to the devising of incandescent lamps so constructed that the filament when burnt out can be renewed, thus permitting of the further utilization of the other parts of the lamp. The most recent device of this kind is that just patented by Mr. Frank S. Smith, superintendent of the lamp department in the works of the Westinghouse Company in Pittsburgh. He has found that certain compounds of the alkaline with the silicon group of elements may be used to form a portion of the lamp, more particularly the supporting stem which carries the leading-in wires. These compounds are soluble in hot water and have certain physical characteristics which permit them to unite with the wires under the influence of heat, making air-tight joints, and they also unite with the glass portion of the chamber. In this way there is formed a composite inclosing chamber, a portion of which is of glass, while the remainder is of a soluble material.



Smith Separable Incandescent Lamp.

The accompanying engraving, Fig. 1, shows the lamp complate, the leading-in wires C^1 C^2 being carried by the soluble compound *D* which is fused to the glass globe A. Mr. Smith finds that the selection of the best compound depends largely upon the composition of the glass portion of the globe. The greater the proportion of the alkali with reference to the silica the softer will be the resulting compound. The compound, $4Na_2O.5SiO_2$, makes a perfect union with platinum leading-in wires and will also unite with a glass having a sufficiently low fusing point.

SOCIETY AND CLUB NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

At the monthly meeting of council, held at 12 West 31st street, New York City, October 25th, the following associate members were elected:

Arnold, Bion J., consulting engineer, General Electric Company, 4128 Prairie avenue, Chicago, Ill.
Jeffery, D. Herbert, secretary and treasurer, Crocker-Wheeler Electric Company, 430 West 14th street, New York City.
Meyer, Julius, consulting engineer, North American Company, Mills Building, New York City.
Pearson, F. S., chief engineer, West End Street Railway Company, 439 Albany street, Boston, Mass.
Spencer, George Jarvis, electrician, the Yale & Towne Mfg. Company, Stamford, Conn.
Tapley, Walter H., electrician in Government Printing Office, care Public Printer, Washington, D. C.
Van Buren, Gurdon C., electrician, 5 Wilson street, Albany, N. Y.
Wallace, Geo. S., telegraph office manager, Chesapeake and Ohio Railway Company, Box 214, Clifton Forge, Va.
Weaver, Norman R., superintendent of repair department, General Electric Company, 173-5 Adams street, Chicago, Ill.

The following associate members were transferred to full membership:

Pike, Clayton W., Jas. W. Queen & Co., Philadelphia, Pa.
Bishop, Jas. D., electrical expert, J. A. Roeblings' Sons Co., 345 West 34th street, New York City.
Barberie, E. T., electrician, Safety Insulated Wire Co., 234 West 29th street, New York City.
Heinrich, Richard O., electrical engineer, Weston Electrical Instrument Co., Newark, N. J.
Rae, Frank B., electrical engineer, 27 Cleland Building, Detroit, Mich.

At the meeting of the institute in the evening, the three electric railway papers read at the general meeting in Chicago last June were discussed. The titles of the papers are as follows: "Series Electric Traction" by Mr. Nelson W. Perry; "A New System of Electric Propulsion" by Mr. H. Ward Leonard; "Electric Railway and Motor Tests" by Prof. Geo. D. Shepardson and Mr. E. P. Burch. The discussion was opened by Dr. Cary T. Hutchinson, and continued by Messrs. Sprague, Mailloux, Emery, Crocker and Henshaw.

The report of the Committee on Units and Standards was accepted and referred to the sub-committee on Provisional Program for the International Electrical Congress of 1893.

NORTHWESTERN ELECTRIC LIGHT ASSOCIATION.

A meeting of the Northwestern Electric Light Association was held at Oconto, Wis., last month, delegates being in attendance from Northern Wisconsin and Michigan. The object of the meeting was to exchange ideas and the advancement of the electric light business. H. C. Higgins, of Marinette, was elected president; Q. A. Pamperin, of Oconto, secretary. Carl Collins represented Green Bay; A. A. Page, Oshkosh; George A. Davis, Neenah; K. L. Lust, Antigo; C. S. Deball, Sheboygan. Many others were present. A banquet was given at the Beyer House in the evening by Q. A. Pamperin.

THE TELEPHONE WIRES IN CINCINNATI.

The telephone wires of Cincinnati, O., are to be taken from the streets, and made to radiate from poles placed in the centre of blocks connecting with the underground system at the foot of the poles. In this way no wire will cross a street. The distributing poles will be provided with a platform near the top supporting an iron ring, equipped with 104 insulators. A cable will be led from the main subway, by a smaller conduit, to the foot of the pole and then up the pole to a point opposite the distributing ring. The terminal head holding the feed wires is covered by a galvanized iron hood, raised by a pulley above it. From under this hood 100 wires will pass, gathered into five cables, to the edge of the bottom floor and then up to the distributing ring. These poles are the device of Mr. W. H. Robinson, superintendent of construction of the telephone company.

HARVARD UNIVERSITY.

The Electrical Department of the Scientific School has been fitted with a Thomson-Houston 500-volt motor and a complete set of shop machinery, including two machine lathes, two speed lathes, a drill press, and milling machinery.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED OCTOBER 18, 1892.

Alarms and Signals :—

Electric Fire Alarm, J. J. D'Almeida and J. Y. de Silva, Lisbon, Portugal, 484,886. Filed May 2, 1890.

A thermostatic fire alarm.

Fusible Fire Alarm, G. B. Smith, St. Cloud, Minn., 484,469. Filed May 10, 1892.

A thermostat employing a non-metallic fusible insulating material and two springs pressing against this insulation and normally kept out of contact thereby.

Combination Lock and Alarm, R. Baumann, St. Louis, Mo., 484,577. Filed Aug. 20, 1891.

A sliding drawer containing a battery and bell and electrical connections for automatically closing the signal when the drawer is tampered with.

Electrical Railway Signal, B. C. Seaton, Nashville, Tenn., 484,614. Filed March 1, 1892.

An electric alarm signal for steam railways.

Draught Indicator for Vessels, W. R. Patterson, Manistee, Mich., 484,642. Filed July 18, 1892.

Employs a standpipe in the hold of the vessel communicating with the water outside, a float within the pipe and an electric signal which operates when the float reaches a certain predetermined position.

Burglar Alarm, A. Stromberg, Chicago, Ill., 484,761. Filed July 19, 1892.

A flexible covering adapted to be placed at doors, windows, etc., and to sound an alarm if disturbed.

Electric Bell, J. E. Thron, Philadelphia, Pa., 484,762. Filed June 18, 1892.

The invention consists in combining the armature of the electromagnets with a secondary lever carrying the hammer upon a flexible arm, spring actuated in one direction and drawn away in the other direction by means of a trip-pawl controlled by the moving armature.

Distribution :—

System of Electrical Distribution, D. B. Brace, Lincoln, Neb., 484,549. Filed Sept. 16, 1891.

Provides means for simultaneously transmitting periodic and continuous currents.

Dynamos and Motors :—

Regulator for Dynamo Electric Machines, C. E. Scribner, Chicago, Ill., 484,611. Filed May 5, 1890.

Relates to that class of regulators in which the connecting brushes are automatically shifted to increase and decrease the electromotive force.

Electric Motor Dynamo, A. W. Smith, San Francisco, Cal., 484,724. Filed Jan. 25, 1892.

Employs a ring armature with a Gramme winding and two field magnets having their unlike poles in close proximity placed at diametrically opposite points of the armature.

Frame for Electric Dynamos, J. B. Fralley, San Francisco, Cal. Design 21,906. Filed Aug. 16, 1892.

Heating:

Electrically Heated Hand-Stamp, J. B. Venker, St. Louis, Mo., 484,574. Filed Dec. 11, 1891.

The combination with a base plate and contact plate, of electrical resistance located at the back of the contact plate and insulated from the base plate, and inwardly projecting pins between the plates to retain them in their proper relative position.

Lamps and Appurtenances :

Lantern for Electric Lighting, D. S. Page, Malden, Mass., and J. L. Bertsch, Cambridge, Mass., 484,449. Filed Dec. 12, 1891.

Electric Light Fixture, D. S. Page, Malden, Mass., 484,450. Filed Dec. 12, 1891.

The invention consists of a water-tight chamber enclosing the incandescent lamp and separated from the woodwork to which it is attached by an air space.

Electric Lighting System, B. B. Ward, New York, 484,479. Filed Mar. 1, 1892.

Claim 2 follows:

The combination with electric arc lamps run in series on constant potential mains and each having a main and a derived circuit magnet with a movable, core, of a mass of iron opposite the ends of the cores for both magnets in each lamp of the series.

Hanger-Board for Electric Arc Lamps, B. B. Ward, New York, 484,480. Filed April 30, 1892.

Electric Arc Lamp, C. Coerper, Coeln, Germany, 484,530. Filed June 18, 1892.

Has for its object to provide a simple feeding mechanism for the carbons, and a reflector which will not become blackened with use.

Electrode and Incandescent Electrical Conductors, L. L. Jones, Brooklyn, N. Y., 484,553. Filed Sept. 16, 1885.

Process consists in mixing a solution containing a non-conducting earth and a metal, then drying the mixture, converting into oxides, and forming into an electrode.

Mast-Arm for Electric Light Poles, A. B. Allison and G. B. Scott, Pittsburgh, Pa., 484.565. Filed March 21, 1892.

Lamp Socket and Circuit Closer Therefor, S. Bergmann. New York, 484,580. Filed May 18, 1892.

Employs an insulating body in the socket having at one end two springs, one connected with the central contact of the socket and the other being a switch spring.

Metal Working :—

Apparatus for Refining Metals by Electricity, C. R. Fletcher, Boston, Mass. 484,416. Filed Nov. 25, 1891.

Apparatus for Annealing Wire or Metallic Rods by Electricity, J. H. Hunter, Pittsburgh, Pa., 584,637. Filed June 2, 1891.

Apparatus for the Manufacture of Metallic Articles by Electrolysis, A. S. Elmore, Leeds, England, 484,704. Filed July 23, 1891.

Miscellaneous:—

Lightning Arrester, E. Searing, Denver, Col., 484,466. Filed Jan. 20, 1892.

Employs a pair of electrodes enclosed in a tube containing a non-striking vacuum.

Insulating Joint, C. Wirt, Chicago, Ill., 484,483. Filed Aug. 29, 1891.

Electrode for Medical Purposes, E. H. McBride. Springfield, Mo., 484,522., Filed July 21, 1692.

An electrode having a non-conducting casing for cataphoric medication.

Drawing and Stippling Pen, J Phillips, London, England, 484,523. Filed May 1, 1892.

Electrical Curling Iron, A. D. Gardner, Lynn, Mass,. 484,532. Filed Oct. 21, 1891.

Apparatus for Electroplating, F. B. Howard, Irvington, N. J., 484,535. Filed Aug. 13, 1890.

Electrical Inductorium, L. S. M. Pike and H. T. Barnett, London, Eng., 3. Filed Feb. 5, 1892.

Employs a dehydrated liquid hydrocarbon surrounding the inductorium and means for maintaining a continuous flow of liquid.

Electrical Inductorium, L. S. M. Pike and E. S. Harris, London, Eng., 484,544. Filed Feb. 5, 1892.

Employs U-shaped plates interleaved with porous insulating material and applied alternately to opposite ends of the coil and bolted together in groups.

Process of Duplicating Phonograms, T. E. Edison, Llewellyn Park, N. J., 484,582. Filed Mar. 30, 1892.

Phonograph Cutting-Tool, T. A. Edison, Llewellyn Park, N. J., 484,583. Filed Mar. 27, 1890.

Phonograph-Reproducer, T. A. Edison, Llewellyn Park, N. J., 484,584. Filed Mar. 27, 1892.

Phonograph, T. A. Edison, Llewellyn Park, N. J., 484.585. [Filed Mar. 30, 1890.

Electric Appliance for Canes, S. D. Smith, Milwaukee, Wis., 484,618. Filed Dec. 7, 1891.

A walking stick containing a source of electric energy and a switch for making and breaking the circuit.

Railways and Appliances :—

Skylight for Electric Cars, H. Cochran, Chester, Pa., 484,515. Filed Mar. 23, 1892.

Switches and Cut-Outs :—

Electric Fuse Box, W. Stanley, Jr., and J. H. Kelman, Pittsfield, Mass, 484,545. Filed Dec. 21, 1891

Telephones and Apparatus :—

Multiple Switchboard System, C. E. Scribner, Chicago, Ill., 484,612. Filed Jan. 21, 1892.

The invention consists in winding each individual annunciator differentially and connecting the branch of the line connected with the springs of the switches through one of the differential windings and the branch which connects the test pieces to the other of the differential windings.

Substation Apparatus for Telephone Systems, C. E. Scribner, Chicago, Ill., 484,613. Filed Jan. 21, 1892.

Employs a signal receiving apparatus and a telephone at the substation, both being in permanently closed and independent parallel branches between the sides of the line.

Telephone Exchange Apparatus, J. J. Carty, New York, N. Y., 484,626. Filed Nov. 29. 1889.

Claim 1 follows:

A coil of a telephone apparatus connected between the strands of a flexible cord and a branch connection to ground at the centre of said coil in combination with a metallic circuit, including the strands of said cord in different sides thereof.

REPORTS OF COMPANIES.

THE WESTERN UNION TELEGRAPH CO.

At the annual meeting of stockholders of the Western Union Telegraph Co., the two vacancies in the board of directors, caused by the death of Messrs. Cyrus W. Field and Sidney Dillon, were filled by the election of Messrs. Henry B. Hyde and G. Murray Crane. From the report of the treasurer, it appears that there has been an increase of gross revenues over those of last year of $672,078 and a reduction of gross expenses of $120,884. The average rate of tolls has been reduced .9 cent, and the average cost of service, a similar amount. During the year 1,595 miles of poles have been planted, 23,512 miles of new wire strung and 602 new offices opened. The capital of the Western Union has now been made $100,000,000

PERSONAL.

Mr. Max Luhn, engineer of the Helios Co., Cologne-Ehrenfeld (Germany), who, after a journey of information in this country, on the 26th of October, returned to Europe on the "City of Paris," was not only very much pleased with what he has seen in the electrical field in America, but also with the kind reception he has received everywhere. He begs us to thank, in his name, the different companies, and the engineers whom he has met, for their kindness, and he invites them (if they should come to Germany) to visit him and the factories of the Helios Co.

LEGAL NOTES.

EDISON ELECTRIC LIGHT COMPANY AND EDISON GENERAL ELECTRIC CO. vs. SAWYER-MAN ELECTRIC CO.

One of the consequences of the recent decision of the U. S. Appellate Court in the Edison lamp case, is the revival of the old suit of T. A. Edison and the Edison Lamp Co. *vs.* Sawyer-Man Electric Co. The old suit is discontinued and a new one instituted by the Edison Electric Light Co. and Edison General Electric Co., the latter being successor to the rights of Mr. Edison and the Edison Lamp Co. Basing their action upon the recent decision of the Appellate Court the complainants have served notice of a motion for a preliminary injunction, to be heard Friday, November 4, in the United States Circuit Court, Southern District of New York.

COSTS IN THE EDISON LAMP CASE SETTLED.

An agreement between counsel for the Edison and United States Electric Lighting Companies, relative to costs in the incandescent lamp case recently decided by the Circuit Court of Appeals has been reached, and the sum agreed upon, $781.50, has been paid into the treasury of the General Electric Company.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

The firms that advertise are the largest employers of labor.

CARHART-CLARK STANDARD CELLS.

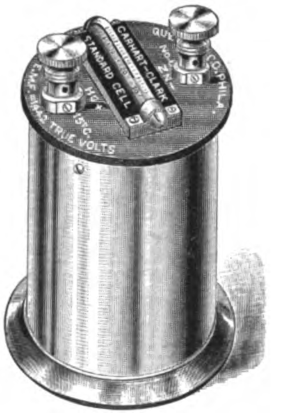
THE accompanying illustration shows a new form of the Carhart-Clark cell with thermometer permanently attached. This type is well and favorably known to scientists both here and abroad, but for the benefit of those who may not remember all of its special features we give the following brief description:

The Carhart-Clark standard cell is the result of several years' study devoted to the subject of standard cells by H. S. Carhart, professor of physics and electrical engineering, at the University of Michigan. Recognizing the fact that all known forms of standard cells had but small endurance, and could not, in the least, stand the jars and strains of transportation without permanently destroying both accuracy and constancy, Prof. Carhart about five years ago started out on a basis of Lord Rayleigh's experiments in standard cells, with a view to making a cell having no local action, perfectly sealed, giving a uniform and constant E. M. F. for all time, and which should not be injured by transportation.

After over two years' study and trial Prof. Carhart, in the early part of 1889, completely solved the problem. The Clark cell, as is well known, is composed of zinc and mercury as electrodes, and mercurous sulphate and zinc sulphate as salts. Great difficulty has always been found in securing the ingredients as a pure state, the smallest amount of foreign matter being sufficient to destroy the reliability of the cell. Another great trouble has been that in transportation, the mercury would be so shaken through the other salts as often to cause a short-circuit. The first of these difficulties Prof. Carhart has overcome by making his own chemicals, the second by the use of a special device, so that any short-circuit in transportation is practically impossible.

One of the chief points of the Carhart-Clark cell is its very low temperature coefficient. By a method discovered only after long and laborious investigation, the temperature coefficient has been reduced from 0.08 per cent. per degree C. to about .0.03, or from 0.00077 to 0.00039, thus making for all practical purposes the temperature change inappreciable. Each cell has, inside of its mounting, an extra graphite resistance of about 10,000 ohms, so that no particular injury will result, should it be accidentally short-circuited for a short time.

The cells proper are prepared by Prof. Carhart at his laboratory in the University of Michigan, and are furnished with his personal certificate of accuracy which also states the exact E. M. F., at 15 degrees C. and the temperature co-efficient of the cell. Queen & Co., Philadelphia, who prepare the mountings for the above have issued a descriptive pamphlet No. 325 which, along with other information regarding the cells contains reports of some exhaustive and very flattering tests. A copy can be obtained from them for the asking.



CARHART-CLARK STANDARD CELL.

BALL ENGINE CO. OF ERIE, PA.

THE BALL ENGINE COMPANY, of Erie, Pa., report that they are having the largest amount of business in their existence, and have enough orders to carry them well through the winter. Among some of their recent orders are the following:

Brockton Street Railway Co., Brockton, Mass., one 600 h. p. cross-compound; Calumet Street Railway Co., Chicago, Ill., four 300 h. p. cross-compound; San Leandro Street Railway Co., San Francisco, Cal., one 500 h. p. tandem compound; East Oakland Street Railway Co., San Francisco, Cal., one 400 h. p. tandem compound; Englewood Electric Light Co., Chicago, Ill., one 600 h. p. cross-compound; Binghampton Electric Light Co., Binghampton, N. Y., two 250 h. p. tandem compound; Wheeling Street Railway Co., Wheeling, W. Va., three 250 h. p. cross-compound; Pottstown Electric Light Co., Pottstown, Pa., one 250 h. p. cross-compound; Erie Electric Motor Co., Erie, Pa., three 150 tandem compound.

THE GERMANIA UNIVERSAL TIN SHADE.

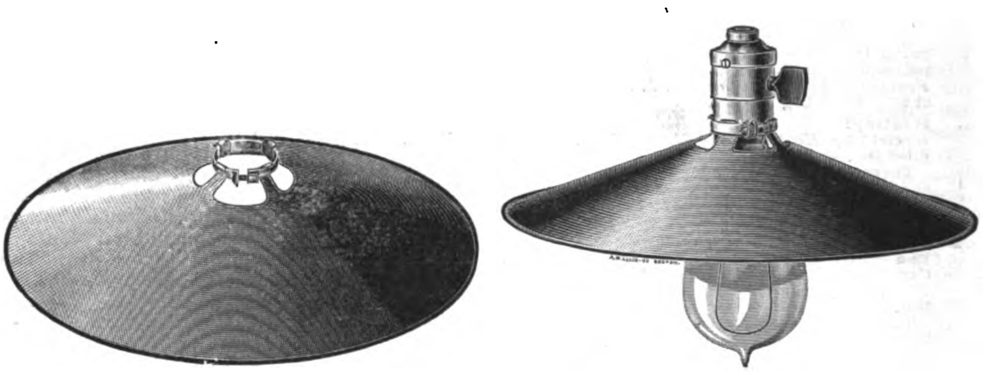
To the trade, which is already familiar with the Germania Universal shade holder, the convenience of the tin shade recently devised by the Germania Electric Co. of 620 Atlantic avenue, Boston, here described, will be at once apparent, it being essentially that shade holder stamped directly from the material of the shade itself, and applicable to any socket without any difficulty of adjustment of screws or any centering whatever.

The holder attachment consists of four little lugs or fingers stamped from the centre of the shade; the ends of these lugs are then turned upward for about a quarter of an inch, and outward again just sufficiently to form a catch for the clamping ring, which is adjustable to the size of any of the sockets on the market by means of the screw which fastens it together.

To apply this shade to any of the regular sockets, the ring is removed and the lugs sprung around the outside of the socket shell and allowed to rest upon the fillet at the edge of the shell. The ring is then placed around the outside of the lugs and the screw tightened so that the shade is clamped firmly in place. When it is desired to attach this shade to the regular Edison socket, the ring is dispensed with entirely, and after removing the rubber bushing from the socket, the lugs are pushed inside the shell where the little projections catch in the fillet of the socket shell, allowing the bushing to be screwed into position again, which in entering the shell holds the shade securely.

This construction is a great advance, as the holes around the socket allow a circulation of air tending to cool the lamp,—a material factor in lengthening the life of the filament.

It is not intended to sell these shades in any finish other than with a fine enamel which gives a smooth white surface wearing for years, and which can be readily washed and kept clean; a material much preferable to lead paint in retaining its color and not becoming yellow by age. On the outside the finish is a fine glossy green japan. The saving in expense of both the shade holder and labor in attaching the shade to the shade holder, also recommends this handsome piece of apparatus.



THE GERMANIA UNIVERSAL TIN SHADE.

PHOTOGRAPHIC PAPER FOR COPYING TRACINGS.

A PHOTOGRAPHIC paper for copying tracings, which gives black lines on a white ground, is being put on the market by Schwenke, Kirk & Co., of 26 Church street, this city. Not only has this paper the obvious advantage over ordinary blue prints of giving more suitable colors for the ground and lines, but after exposure in the printing frame the only treatment required for developing and fixing is a plain water bath. A paper of this sort has long been desired by engineers, and many inventors and chemists have searched for years for some compound which could be used in the preparation of such a paper. The compound appears to be an organic substance, which can be bleached by the sun, but is precipitated as a dark purple powder when it and its suspending medium are brought into water. This powder forms a black deposit in the paper and is quite permanent. The price of the paper is not any higher than the best blue-print paper, and it entails no expenditure for developing chemicals.

Mr. A. L. Rohrer.—A magnificent farewell dinner was given Mr. Rohrer on the occasion of his leaving the Lynn factory of the General Electric Co., for the factory at Schenectady. When he went to the Lynn factory eight years ago they employed 100 men. The number to-day is about 3,000. The dinner was given at the Hotel Thorndike, Boston, and Prof. Elihu Thomson was present.

NEW YORK NOTES.

The C. & C. Electric Motor Co. reports the following recent sales made by this company through its New York, Chicago and Boston offices: Menominee Electrical and Mechanical Co., Menominee, Mich., a 15 h. p. and a 3½ h. p. motor, and 6, 4 and 3 K. W. dynamos; Baydenoquet Co., Nahma, Mich., a 12 K. W. dynamo; Armour Packing Co., a 25 h. p. motor and two 5 h. p. motors; De La Vergne Refrigerating Machine Co., this city, a 15 h. p. motor. They have orders filled and unfilled from a single crane company for over 50 machines, consisting of one 20 h. p. motor, nineteen 16 h. p. motors, thirteen 12 h. p. motors, nine 8 h. p. motors, the balance being in sizes below 8 h. p. Laclede Power Co., St. Louis, Mo., three 25 h. p. and two 10 h. p. motors; Heidt & Son, Jersey City, N. J., a 20 h. p. motor; H. R. Worthington, Brooklyn, N. Y., 10 and 3 h. p. motor; Harvey Street Car Works, Harvey, Ill., a 30 K. W. plant, including lights and installation; Midvale Steel Co., Nicetown, Philadelphia, Pa., 80 K. W. dynamo and Ball engine, including installation; Boston and Maine Elevator (Messrs. Simpson & Robinson) Charlestown, Mass., 20 K. W. dynamo, lamps and installation; Home for Paupers, Long Island, Boston Harbor, three 13 K W. dynamos, three 5 h. p. and two 2 h. p. motors.

Ball & Wood Co.—Among the engine concerns which will be most prominently represented at the coming Exposition in Chicago, will be the Ball & Wood Company, of No. 15 Cortlandt street, New York, which has arranged with the Brush Electric Company to furnish the Exposition authorities a complete lighting plant. This will contist of five Ball & Wood engines comprising two simple engines, 150 h. p. each, two tandem compound engines, 150 h. p. each, and one cross-compound engine of 200 h. p. These engines will operate 16 Brush dynamos, and three of them have already been delivered and were in use during the recent inaugural ceremonies. These compound engines have been fitted with the new valve covered by Mr. Ball's recent patents, which makes these engines distinctive not only in appearance but in economy. The Ball & Wood Company is now executing contracts at Bethlehem, Scranton, Columbia, Pittsburgh, as well as in a number of other prominent Eastern cities.

WESTERN NOTES.

The Wirt Voltmeter.—Probaby no element of so much real importance is so little appreciated as a good pressure indicator. This will apply to isolated plants more than to central stations, but there is still ample room for improvement with the latter. It is a fact that there are many stations operating large numbers of incandescent lamps that either have no indicator or have one that is of no practical value. One would as much expect to operate a 100 h. p. boiler without a steam guage, as to run even a 50-light dynamo without a volt indicator. Many complaints of short-lived or inefficients lamps can be traced to the absence of an indicator. The Wirt volt indicator made by the Electrical Supply Company, corner of Michigan avenue and Randolph street, seems to be one of peculiarly sensitive adjustment and excellent workmanship, and the manufacturers are in daily receipt of letters expressing the greatest satisfaction with their use.

The Southwark Foundry & Machine Co., of Philadelphia, represented by Mr. Frank W. Bunn, 353 Rookery, Chicago, have just secured the contract from the Chicago Edison Co., for six of their vertical triple-expansion condensing Porter-Allen engines, aggregating 4,240 h. p. rated capacity, for their new station at Harrison street on the river front. Each engine will carry two multipolar Edison generators coupled direct, one on each end of the shaft. Work on these engines will be commenced immediately. The work on the building has been going on for some time. The Southwark Foundry & Machine Co. have almost completed two large vertical 1,200 h. p. engines, one of which we understand is for the Cincinnati Edison Co. of Cincinnati.

Taylor, Goodhue & Ames are pleased with the success which has already attended their efforts, although they have been in the field less than a month. They have secured several nice arc lamp orders, and are also pushing the well-known Burton electric car heater. The demand for specialties made by the Wagner Electric Mfg. Co. and the Columbia Incandescent Lamp Co., for which they are agents, is brisk. Orders for the Philadelphia trolley, which made so favorable an impression upon practical men at the recent Cleveland convention, are beginning to come in. Taylor, Goodhue & Ames report business in all their line of specialties as excellent.

The Mosher Electric Co., 125-127 Ontario street, Chicago, of which Mr. G. L. Reimann is president, John A. Mosher, the patentee of the lamps, vice-president, and Mr. John A. Sherriff, secretary and treasurer, report a prosperous and increasing trade in Mosher arc lamps for all direct and alternating constant potential circuits. Since Sept. 1, when the present officers took charge of the business, more than 250 of these favorite lamps have been shipped and they are unable to keep pace with their orders. They are, however, rapidly increasing their facilities to give them a capacity to turn out 500 lamps per month. They are receiving some very flattering testimonials regarding the burning of these lamps and have some specially fine ones concerning the operation of their series lamps burning ten in series on constant potential circuits.

The Siemens-Halske Electric Co. of America have now sufficient large contracts on hand to keep their factory busy for three months at least. Their apparatus is being received with general favor throughout the country, and everything points to their securing a large share of the electrical business of the country which is every day increasing. Work on their factory is being pushed along rapidly, and when completed it is expected to be one of the most complete and best equipped in the United States.

The Sunbeam Lamp.—The meritorious features of the Sunbeam lamp are beginning to be publicly appreciated everywhere, and the Sunbeam Incandescent Lamp Co., Chamber of Commerce Building, Chicago, are pushed to the utmost capacity of their factory to fill their many orders. They are now running up till ten o'clock every night and taking on new help as fast as it can be secured. This large trade they consider to be entirely due to the general satisfaction given by their lamps.

Mr. Frank McMaster, traveling representative for George Cutter, electrical specialties, 829 Rookery, is back in the city for a few days. He expects to leave shortly on an extended Western trip. He reports business as good and that the choice line of specialties which he carries, many of which are invented and manufactured solely by Mr. Geo. Cutter, are being received very favorably in all parts of the country he visits.

The Electric Appliance Co. have just patented, and are placing on the market, a new expanding wire guard to be known as the "Acme." It is a decided improvement on anything heretofore attempted in this line, both in appearance and adaptability, and promises to find a ready sale. In fact, the Electric Appliance Company have already booked large orders from a number of jobbers in different parts of the country.

Col. J. H. Shay of the Charles Munson Belting Co., Chicago, had to return from the Cleveland Street Railway Convention owing to sickness. He has been suffering for a couple of weeks from an attack of rheumatism but is now much better and able to be about. The Colonel reports the belting business as excellent and the trade with electrical companies is increasing all the time.

Mr. W. L. S. Love, vice-president of the Pond Engineering Co., has been for some time in Chicago taking charge of the company's office here, and states that it is his intention to make Chicago his permanent home and headquarters. Mr. Love reports some large contracts on hand for complete steam power plants and business as first-class generally with a very encouraging outlook.

The American Battery Co., 177 La Salle street, Chicago, manufacturers of storage and dry batteries, are in receipt of numerous orders for their Planté type of cells, for the advantages of which they make many strong claims. Among other points in which it is stated they excel, is their immense durability and the capability of withstanding the heaviest discharge without injury.

The Illinois Electric Lamp Co.—The lamps manufactured by the Illinois Electric Lamp Co. are in great demand. Mr. Bennett, manager of the company, says that they have all they can do to keep pace with their orders, but they are rapidly increasing their output, and that the quality of the same receives the due appreciation of their customers.

Mr. J. H. Cooke, manager of the Chicago office of the Buckeye Electric Co., 427 Rookery, is furnishing a great many of their lamps to users in all parts of the country. Mr. Cooke is one of the old dealers in the lamp business and knows just how to push a good article.

Clark & Marshall, the Rookery, Chicago, are doing a good business with the Boston incandescent lamp and the other line of specialties which they are handling. They expect to add several new and valuable devices to their line within the very near fature.

Mr. Alfred E. Kornfeld, New York representative of *The Electrical Age* and *Street Railway News*, was among the recent visitors to Chicago. Mr. Kornfeld is looking well and enjoying his visit to the Western metropolis.

The Post-Boynton-Strong Co. are receiving a great many orders for their crowfoot battery zincs. These goods are guaranteed to be made only from virgin spelter, assaying 99.354 per cent.

The Valentine-Clark Co., No. 540 Rookery Building, Chicago, are meeting with a large sale of their poles and ties for street railway purposes. The demand also for poles for electric lighting is very brisk. Their business during the past season has been exceptionally good, and during this fall they are expecting a largely increased demand and are busily preparing themselves to meet it. They intend carrying a greatly increased stock on hand at all times and are establishing more yards at various initial points, enabling them to handle orders from any section of the country with despatch. They are representing the Walworth Manufacturing Co. throughout the Western territory on their famous tubular steel poles and have booked a number of good orders for them already this season.

The Mosher Arc Lamp and Manufacturing Co., of 127 Ontario street, Chicago, have recently largely increased their facilities for turning out their lamps, which are becoming great favorities for incandescent and power and street railway circuits. Their orders are continually on the increase, and reports from customers indicate that they are greatly pleased with the lamps. They are placing on the market also, an entirely new form of arc lamp for alternating current circuits for which some very remarkable results are claimed.

Mr. Walter A. Crowdus has now perfected a special dental outfit operated by his well-known primary batteries which he has recently greatly simplified and increased in efficiency. He has also brought out a complete sewing machine outfit which promises to come into widespread use. For his work he has designed a special form of small motor which gives excellent results, absorbing very little energy. All these goods are manufactured by the Union Electric Works, Springer Building, Chicago.

Mr. Thos. G. Grier, Western manager of the Bryant Electric Co., who has offices at 1522 Monadnock Building, is very busy and the demand for their specialties is steady. Mr. Grier, L. K. Comstock and E. E. Shaw are delivering a series of lectures on physics and electrical engineering at the Hull House, No. 335 South Halsted on special evenings from 7.30 to 9.30. We are glad to see some of the electrical fraternity turning their attention from business to philanthropic objects such as this is.

The Q. & C. Co., 703–707 Phœnix Building, successors to Dunham Manufacturing Co. are doing an extensive business in their railway specialties. Among other goods which they control are the Dunham car door, the Q. & C. trolley, Davis spike, Consolidated brake adjuster, and Globe ventilator. They have also recently sold a great many of the Bryant metal sawing machines which they manufacture in several styles for both mechanical and hand power.

The Indiana Rubber and Insulated Wire Co., whose office is No. 242 Madison street, Chicago, are pushing the capacity of their factory at Jonesboro, Ind., with numerous, large orders they are receiving for Paranite wires and cables. The rubber used in the manufacture of these wires is of the highest grade, being pure Para, and it is reported that they are giving the very best satisfaction wherever they have been used.

The Bain Electric Manufacturing Co. have furnished a specially designed direct coupled generator to the Patton Motor Co. This machine is connected direct on the gas engine shaft and develops over 30 electrical h. p. at 250 r. p. m. It operates very well in every respect, running with no sparking and perfectly cool; Mr. Patton is delighted with it and satisfied that the efficiency is from 85 to 90 per cent.

The Patton Motor Co. have just completed one of their new cars, equipped with direct connected generator which was designed by Mr. Foree Bain. The truck is of special pattern having six wheels and runs without any noticeable oscillation over even rough track. This car makes a speed of from 25 to 30 miles an hour and gives excellent satisfaction. They are now building a number of similar cars.

Mr. Chas. G. Burton, city selling representative of the C. & C. Electric Motor Co., is kept busy making sales of these well and favorably known machines. Mr. Burton is one of the old timers in the electric light and motor business, having been connected in a selling capacity with several of the prominent companies for many years and is known all over the West as an energetic hustler.

Taylor, Goodhue & Ames, Monadnock Building, are very much pleased with their opening business, many orders coming from the country. They recently sold a large number of arc lamps to one plant. Satisfactory orders are coming in daily. Columbia lamps are selling well and giving great satisfaction to all using them.

Mr. J. K. Pumpelly, the well-known storage battery inventor, is perfecting a new form of cell, one of the features of which is a special porous partition and retainer. This battery, it is stated, is a new departure and is remarkably cheap and efficient.

The Railway Equipment Co., Pullman Building, Chicago, are doing a large volume of business. The demand for their electric railway supplies has been unprecedented recently. They have had hard work to fill all their orders with the promptness for which they are noted, but by strenuous efforts have succeeded in keeping up pretty well with their orders.

Wm. Hood & Co., managers of the Chicago office of the Electric Manufacturing Co., of Oconto, Wis., are receiving numerous orders for Brilliant incandescent lamps. It is a familiar daily sight to see Brilliants being shipped out in barrel lots to all parts of the country.

Mr. R. Fleming, electrical engineer, who is associated with the Rockford Electric Manufacturing Co., of Rockford, Ill., as superintendent of their shop, was in Chicago last week and found time to drop in at the Western office of The Electrical Engineer.

The Rockford Electric Manufacturing Co., of Rockford, are just installing a 500 incandescent lighting plant in the Chicago Oyster House. This adds another to the numerous plants they already have here for lighting and power service.

Clark & Marshall, 413 Rookery Building, Chicago, will soon have their new pamphlet of their numerous specialties ready for distribution. This is a very complete little work and shows the advantages and merits of the goods they handle.

The Central Electric Co. are meeting with great success as usual on Okonite wire, a very large amount of which is being used for the extensive new construction work and additions now going on.

Mr. Love, manager of the Chicago office of the Pond Engineering Co., reports having several important contracts on hand for complete steam plants for electric lighting and railway work.

Mr. L. K. Comstock, consulting engineer and contractor, 1419 Monadnock Building, Chicago, is busy installing motor and lighting plants and on various lines of consulting work.

Mr. S. M. Hamill, secretary and general manager of the Brush Electric Co., Cleveland, Ohio, was among the recent electrical visitors to Chicago.

PHILADELPHIA NOTES.

The New Odd Fellows' Hall Plant.—After months of great anxiety on the part of the several firms competing for the work, the contract for the steam engines and electric lighting plant of the new Odd Fellows' Hall, Philadelphia, has been awarded to M. R. Muckle, Jr., & Co. The plant will consist of three 10″ and 18″ x 10″ Westinghouse compound engines driving three 425 ampere dynamos to supply the entire lighting of the building. The dynamos will be of the slow-speed type and in all probability rope drive will be used. The special features called for in the fitting up of the lodge-rooms and degree-rooms will make this a particularly interesting installation. The building will be a very handsome one and is to be completed by the middle of 1894. It is certainly a sign of improvement in the times when contracts of this kind are let so far in advance as to enable the parties doing the work to have every opportunity, as the building progresses to make an installation which shall be well planned, thorough, and not expensive to run when completed. It is also interesting and encouraging to notice that five responsible bidders on a contract aggregating nearly thirty thousand dollars were all within a few hundred dollars of one another.

NEW YORK NOTES.

The Alexander-Chamberlain Electric Co., of 126 Liberty street, N. Y., have been appointed special agents in New York and vicinity, for the Riker Electric Motor Co., of 45 York street, Brooklyn, and though the representation is not exclusive they have already disposed of about 300 incandescent lights capacity for the Riker Co. who report a lively and increasing demand for their apparatus.

The Conduit Wiring Co., of 12 West 29th street, this city, installed the electrical part of the decorations for the Hotel de Logerot, to which a gold medal was awarded by the Committee on Art of the Columbian celebration.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.***

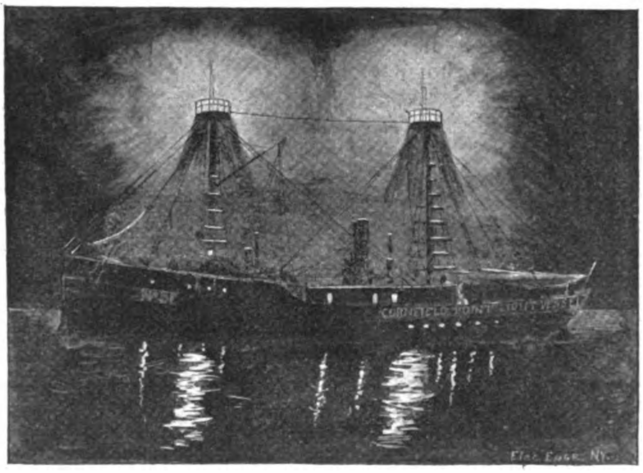
THE
Electrical Engineer.
VOL. XIV. NOVEMBER 9, 1892. No. 236.

THE FIRST ELECTRIC LIGHTSHIP—THE ELECTRICAL EQUIPMENT OF "No. 51."

BY

George Barton Muldaur

IN view of the rapid advancement of engineering science and the state of perfection to which the art of shipbuilding has been reduced, it seems rather odd that so indispensable a public servant as the lightship should have been so long left in an almost primitive stage of development. These vessels, moored at points along the coast where lighthouses cannot be built, and where, but for a permanent signal of some kind, lives and cargoes would be constantly sacrificed, are massive old tubs, staunch and reliable, it is true, while securely anchored but almost helpless when, as not infrequently occurs, some more than usually severe storm compels them to slip their cables and drift out to sea. They are built to float, not to sail, and when missed from their proper positions must be searched for and brought back by tugs or government vessels. The Cross Rip lightship in Nantucket Sound was once lost for more than a month and was finally discovered in the Gulf of Mexico with all hands safe, but subdued.



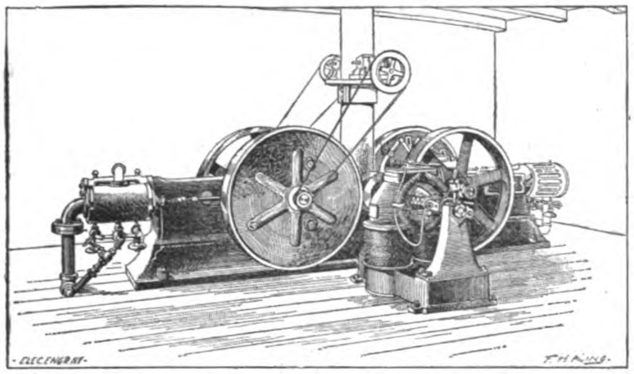
LIGHTSHIP No. 51, WITH ELECTRIC LANTERNS.

Then, too, in regard to the lighting; an immense lantern containing eight lamps with their reflectors is arranged to surround each of the two masts, and can be raised at night and lowered in the morning by the aid of a counterpoise weighing a ton. As the lantern, of course, is equally heavy, this weight is always at the top of the mast and adds greatly to the vessel's tendency to roll. At the base of each mast, and completely surrounding it, is a little house built on a raised platform and having a slanting roof that opens to receive the lantern and shelter the men while tending it. As the real masts are thus used exclusively as derricks, a supplementary mast is provided about four feet abaft each light mast, and on these are carried fore and aft sails to be used in case of emergency. The complete equipment is extremely antiquated in design and clumsy in appearance, though picturesque enough and affording, perhaps, the only remaining parallel to the good old days of the whalers.

Sentiment and poetry can readily be dispensed with, however, where safety to life may be secured by methods of practical utility, and four new vessels have accordingly been built at the yards of Messrs. F. W. Wheeler & Co., of West Bay City, Michigan, designed by Mr. Walfrid Sylven, C. E., a superintending engineer of the Lighthouse Establishment, under the personal direction of Commander Geo. W. Coffin, U. S. N., Naval Secretary of the Lighthouse Board. They are iron steamships of the most approved design, capable of sustaining a sea speed of nine knots per hour and of taking care of themselves in storms. The first of these, known as "No. 51" and to which will be entrusted the guardianship of Cornfield Point in Long Island Sound, has been fitted with a complete electric plant under the direction, and at the suggestion, of Commander Coffin, and in accordance with the specifications of Major D. P. Heap, U. S. A., engineer of the Third Lighthouse District, with headquarters at Tompkinsville, Staten Island, and is the first electric lightship in the world. Commander Coffin and Major Heap have long been firm in the belief that the incandescent electric light was perfectly adaptable to lightships, certain authorities to the contrary notwithstanding, though the white rays of the arc light are said to be more readily absorbed by fog than those of the oil lanterns in general use, the latter having a yellowish tinge that shows in a fog by contrast.

The incandescent light has, therefore, been employed on No. 51, and the utmost care has been taken to foresee and provide for all possible accidents to any part of the plant. The entire equipment is in duplicate. The dynamo-room, consisting of a deck house at the foot of the after mast, contains two Thomson-Houston dynamos wound for 110 volts and having a capacity of 100 lights each. These are driven by two Ideal engines of eight horse power each, running at 400 revolutions per minute. The dynamos are fitted with Evans friction cones, and the arrangement is such that each engine can run either generator or both, if desired, the change being made very rapidly by means of double-acting ratchets and sliding bed plates. The actual floor space occupied by the dynamos and engines does not exceed nine by eight feet. Each dynamo is amply capable of lighting the entire vessel by itself, but two are used for the sake of safety. If desired, either generator can furnish current to the mast-head lights and the other one to the lamps below decks, and in fact, the whole system is entirely interchangeable. Duplicate armatures and rheostats are kept ready for emergencies in addition to such accessories as brushes, switches, fuse blocks, etc.

The mast-head lights consist of eight 100 candle power lamps, four on each mast in multiple. Each lamp is placed in a separate lantern with the triple loop of its filament in the focus of the lens, and the four lanterns are symmetrically placed about the mast-head. Lead-covered Habirshaw cables of seven strands imbedded in the masts carry the current to these lights. If, in spite of all the precautions that have been taken, the electric plant, or a part of it, should become disabled, the lamps may be quickly removed from the lanterns, the sockets instantly moved out of the way, and oil lamps substituted while repairs are being made. The lanterns, it should be added, are swung on trunnions to keep the beam of light horizontal. In order to distinguish one from another, light vessels, as well as lighthouses, are provided with revolving lenses, making flashes of a certain duration; thus a ten second flash with a five second interval may show the pilot who has lost his bearings that he is not far from the right course, while a twenty second flash and a fifteen second interval shows him that he has been driven away up the coast and is in the neighborhood of a dangerous reef. The combinations are infinite and each has its especial significance. In this instance, however, instead of the heavy revolving lens operated by a separate engine and requiring careful attention, a very simple interrupter is employed, regulating the length of the flash to a nicety, and entirely automatic in its action. This little device consists of a ratched shaped cam revolved by means of a worm gear at a speed of one complete turn per minute, and divided into the proper number of steps to produce the particular number of flashes required. The gearing is run by a light helical wire belt from the engine shaft. The cam is made of hardwood with every alternate step covered with copper, and upon its face bear two brushes side by side, but insulated from one another, and included in the mast-head circuit. As the cam revolves, therefore, the circuit is alternately closed and opened at sharp intervals. The whole apparatus is only about ten inches in height and stands on a little bracket above the dynamos. The flashing device also throws in a resistance, equal to the resistance of the mast head lights. When the latter are extinguished, this prevents the other lights in the ship from flickering.



Dynamo Plant of Lightship No. 51.

The wiring of the entire vessel is most carefully and thoroughly done. About twenty lights are used for the necessary illumination between decks. In all cases, the wire is capable of carrying twice the current required without heating, and no effort has been spared to make this installation perfect in every respect. The success of the experiment is a subject for sincere congratulation to all who go down to the sea in ships, and to the electrical engineer, who sees in this experiment another glimpse of the vast possibilities of his profession.

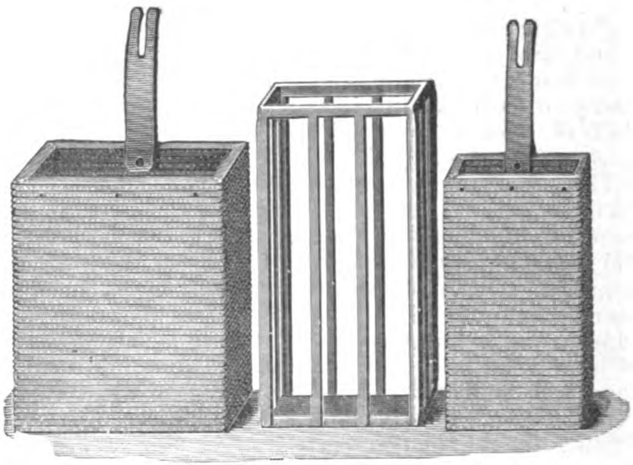
THE SCOTT FLASH SIGNALING LANTERN.

The Brazilian cruiser "Tiradentes," built and equipped at Elswick, went through her trials a few weeks back. After the trials the signaling lamp, invented by Commander Scott, of H. M. S. "Excellent," was exhibited and created great interest. The lamp in question is designed to send signals by the usual flashing method. The lamp can be placed on the top of the mast, or on a special signaling pole; an all-round sphere of action is therefore afforded to it. The operator, however, can be posted wherever convenient. He works the lamp by means of a key. Each time the key is pressed the lamp emits a flash, shutters surrounding a glow lamp being actuated by a system of electromagnets.

THE NEW ELIESON ACCUMULATOR.

In the accompanying drawing we illustrate a new form of accumulator invented by Mr. C. P. Elieson. This accumulator is built entirely on the Planté principle, and it will easily be perceived that although it is only composed of two electrodes, a large amount of surface is, nevertheless, provided for the storage of electrical energy. In the accompanying illustrations for which we are indebted to the London *Electrical Review*, there are shown the three parts composing such an element, Fig. 1 being the negative electrode, Fig. 2 the separator, and Fig. 3 the positive electrode. The positive electrode is inserted in the skeleton box, Fig. 2, the whole is then placed into the negative electrode; a hard rubber box is provided with a rim extending one inch from the bottom of the box, upon which rim the negative electrode rests so as to prevent any possible short-circuiting from the agglomeration of oxide dropping at the bottom. Fig. 4 gives a view of one electrode, where a portion is removed in order to show the internal construction; it is built up of a series of corrugated and perforated envelopes of thin lead. Each of these envelopes is built up on top of the other, and each corrugation is so arranged as to run across or at an angle with the corrugation of the next envelope; in practice, nine of such envelopes compose one electrode. The positive electrode, 5 x 3½ x 8 inches, possesses 4,000 square inches of exposed surface, the negative electrode measures 6½ x 4½ x 8 inches. The lugs which are on each electrode run right to the bottom and are burnt through and through in order to secure a perfect metallic connection with each envelope. The weight of the two electrodes is 12½ lbs., or 23 lbs. including box and electrolyte.

It is claimed that such an accumulator requires very little attention, and that the positive electrode will hardly require renewing after 12 months' hard work. The formation process is carried out in the usual way, partly chemically and finished off electrically. The storage capacity of this cell is about 100 ampere hours, but the formation can be stopped at 60 or 80 ampere hours, as it will soon increase in its capacity while in actual work.



Figs. 1, 2 and 3.—New Elieson Accumulator.

It is clear that buckling in this form of accumulator is totally obviated, at least during the first year of work, as there is ample space between the corrugations to allow for the molecular increase of oxide, but the total filling up between the several enevelopes could not, it is claimed, take place before two years of constant work. Although at that time this accumulator would have attained its highest degree of capacity, it would be advisable if used for traction to renew the positive electrode after twelve months' working during which time, it is claimed, no attention whatever would be required beyond replacing the electrolyte lost by evaporation.

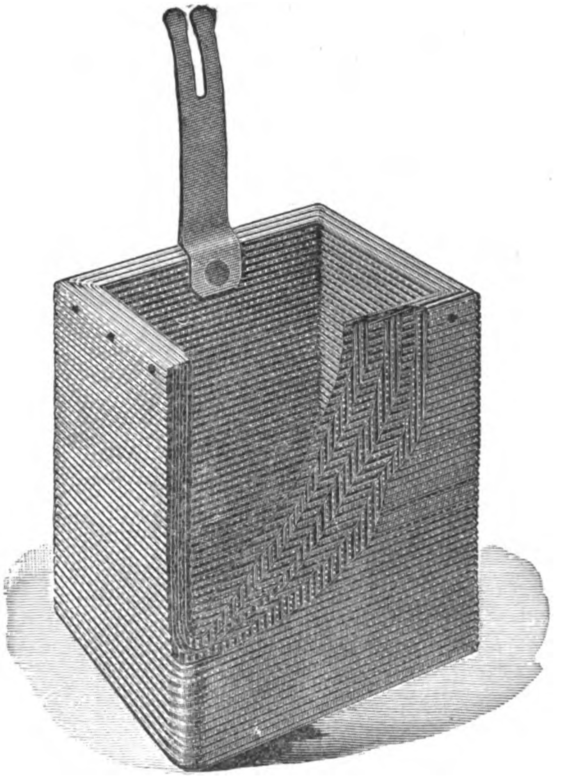


Fig. 4.—New Elieson Accumulator.

THE SOLAR CONSTANT.

BY

I. Thornton Osmond

In 1886, I devised some experimental tests of Maxwell's electromagnetic theory of light, some of which were subsequently executed, and a few notes concerning them published in The Electrical Engineer, March, 1889. The apparatus and the conditions of work, at the Pennsylvania State College, were so poor that it was impossible to be certain of the results. In September, 1889, Dr. Sheldon published, in *Silliman's Journal*, an account of similar experiments, on the same principle but with better apparatus and conditions, in which he claimed a positive result. Dr. Brackett repeated the experiments, without result, and believes Dr. Sheldon to be mistaken.

But direct experimental proof of Maxwell's theory is no longer necessary. The work of Dr. Hertz and of Mr. Tesla has established the identity of certain electromagnetic actions and light. The solar radiation is an electromagnetic action, a transmission of energy in the electromagnetic form or state.

All attempts to determine the *solar constant* have assumed that the energy is either in the form of heat or in some form *totally convertible* into heat by the apparatus used. If, then, this be not true, we have as yet no measure of the flow of energy from the sun upon the earth. It is now certain that the energy of the solar beam is not heat, that it is electromagnetic in its nature. That the apparatus used to measure the energy thus transmitted should have an efficiency of 100 per cent. as a converter of electromagnetic into heat energy appears very improbable.

I have tried to gain a little knowledge upon this subject by some experiments. The apparatus consists of an eight-pole Westinghouse alternator, running at 2,000 revolutions per minute, at 1,000 volts, a Stanley transformer (10:1), an induction coil of special construction, thermopiles and galvanometer, or delicate thermometers.

The induction coil was made especially for this work. The outer coil is 6½ inches long, wound on a spool 5½ inches in diameter, 1,456 turns. This spool has a hole 2¼ inches in diameter, for the inner coil leaving a wooden tube with walls 1¼ inch thick between the coils. In these walls, on two opposite sides, pockets of the same width and nearly the full length of the coil are formed, parallel to the axis and between the coils. In these, substances may be placed or rubber or glass tubes may be filled with substances and inserted. The relative efficiency of two substances as converters of the electromagnetic energy of a field into heat is determined by delicate thermometers or the thermopile and mirror galvanometer, together with the mass and specific heat of the substances.

Several trials of mercury and iron (fine turnings) indicate the latter to be at least as efficient as the former in converting electromagnetic energy into heat. (Aside from other difficulties, it is almost impossible to know with precision the relative amounts of energy that will pass through the same form and volume of mercury and of iron filings similarly situated in the same electromagnetic field.)

Experience with transformers in electric lighting has shown that in good iron but very few per cent. of energy is lost in heat in the iron core. Suppose that poorer iron converts even as high as 10 per cent. Then, if mercury is a less efficient converter of energy of the one form into the other, it converts less than 10 per cent. And the value of the *solar constant* determined by the heat evolved in mercury is *less than* 10 *per cent. of its true value.*

Through every square metre area perpendicular to the solar radiation, if I am not greatly in error, there flows at least 1 h. p. of energy, and that already in the most valuable form known. Its utilization, direct and unconverted, is the last great problem in rendering all the powers of nature tributary to the service and well-being of man.

ARTIFICIAL INDIA-RUBBER.

Dr. W. A. Tilden discovered some months ago that isoprene, which can be prepared from turpentine, under certain circumstances, changes into what appears to be genuine india-rubber. Bouchardat had also found that the same change could be brought about by heat. The material so produced resembles pure Para rubber in every way, and, whether it is genuine rubber or not, it may be equally good for all practical purposes. It vulcanizes, for instance. It therefore seems possible, says *Industries*, that we may soon be able to make india-rubber commercially. If this is possible, a fortune awaits the inventor who can make good rubber from turpentine at a reasonable price. It is a subject well worthy of the devotion of prolonged labor.

THE MAGNETIC CLUB.

The autumn meeting of the Magnetic Club will be held at Morello's, 4 West Thirty-ninth street, on November 16. Dinner will be served at half past six o'clock, and a full attendance of the members is requested.

THE KEYSTONE REVERSIBLE MOTOR FOR ELEVATOR SERVICE.

The growing demands of the electric elevator field continue to attract the attention of progressive inventors and manufacturers. The constant addition to the number of high office buildings and factories, and their contiguity to central stations in all large towns and cities, offer a strong inducement to study the problems involved in equipping them with electric elevators and to produce the apparatus needed.

Among the concerns that have paid special attention to this field for some time past is the Keystone Electric Company, of Erie, Pa., who have already introduced a large number of their equipments with great success; and we are now afforded the opportunity of illustrating and describing their devices and methods, the main feature being their use of the reversible motor, to which reference has been frequently made in these columns.

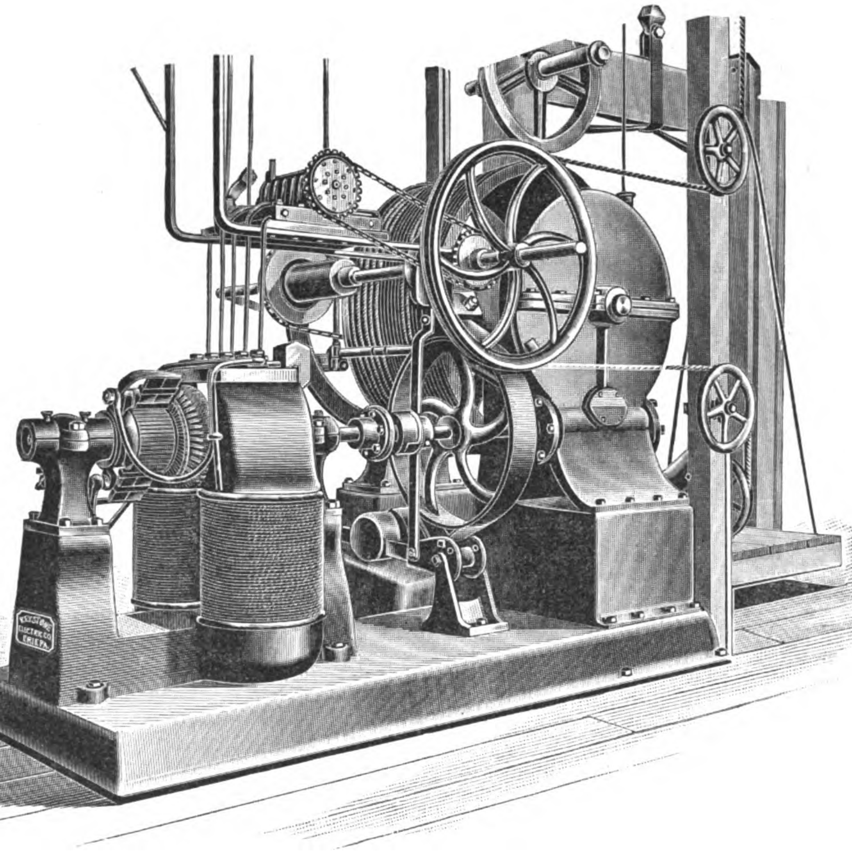

Fig. 1.—The Keystone Reversible Motor Attached to Elevator Winding Drum.

Fig. 1 shows a motor of the Standard type coupled direct to worm shaft of winding gear of an elevator made by Marshall Bros., Pittsburgh, Pa. The car speed of this machine is 200 feet per minute with a load of 1,000 pounds. In operation the machine is practically noiseless, with easy stopping and starting speeds. The reversing switch is placed directly over the motor, with feeder wires coming from above, with short wires from switch terminals to motor binding posts. In this form it is very convenient to wire and occupies but a small space. A sprocket chain connects the switch and brake shaft. This brake shaft is also connected to the shaft of the cable drum, by chain gear, to stop the motor automatically at the top and bottom of the hoist, by operating the switch and the brake at the same time. This same simultaneous operation of switch and brake is controlled by hand cable for stopping at different points, or at the several floor landings. The chain gear used prevents any possible failure of brake and switch operating in unison and in proper time to perform their proper part of the work of controlling the brake and the motor to stopping and starting. The brake is so constructed that upon closing the switch, the brake is instantly released. The car starts with an easy motion when the switch is opened, the brake closes gradually and brings the car to an easy stop.

The frame of the motor is insulated from the iron base of the winding machine. An insulated coupling is also used to provide against any grounding of the circuit through the motor frame and the iron base. The coupling is provided with a crab set apart to allow for any end thrust that might occur by neglect or wear of the worm shaft. The sprocket wheel on the switch is insulated to prevent grounding of the circuit through the hand cable, or through the iron frame of the winding machine. In fact, nothing is left out which in the least could add to the stability of the machine, and the Keystone Electric Company are proud of the fact that for the past two years that they have been installing these motors there have been no failures, while all machines are operating to the entire satisfaction of their customers.

Fig. 2 shows another type of reversible motor, with insulated crab coupling attached. This motor was designed to meet the requirements of elevator builders, for a machine with an armature shaft near the base to admit of building the elevator winding machine compactly. Fig. 3 shows this type of motor attached to the elevator made by M. J. O'Donnell & Co., Cleveland, Ohio, running at a car speed of 190 feet per minute. The frames of these motors are of soft steel castings with brass yokes, self-oiling bearings, with sight-gauges, showing the position of the oil. All terminals are concealed except those to the brushes. The commutators are of tempered copper made with large brush contacts. The bearings in this as in all machines of the Keystone make are designed for long life.

Fig. 4 shows the standard type of Keystone reversible motor for use on elevators where a belt is used to transmit power to the winding drum of the hoist. With this machine a single belt is used, the motor being reversed by means of a reversing switch operated by hand cable on the elevator car.

Fig. 5 shows a view of the reversing switch. It is constructed of heavy parts throughout to give strength and to provide ample contact points for any volume of current required on the largest motors at present used in this service. The base is made of strips of well-seasoned hardwood, glued and bolted together, forming a piece of proper size for mounting the switch. The main axis of the switch is of cast brass separated in the centre by one inch of fibre, with plates cast on the arms from this shaft. The bearings for this axis are of brass well fitted to the journals. On one outer end of this shaft is placed the sprocket wheel insulated with a fibre disc. On the other end is a snap switch constructed as shown. This snap contact closes the circuit just after all the plates have been brought in contact by the rotating switch; and opens the circuit a very little in advance of the plates leaving the contact, thereby bringing all the bad effects of breaking the circuit to that one point. By the snap action of the circuit breaker but little injury is done here. It is at this point only that any attention is required in operating the elevator. These switches have been used for the past two years and seem to be in perfect order. It has not yet been necessary to renew any part of those now in use. In view of the fact that elevator machinery is usually placed in the hands of employees who know and care little about the mechanism, the success of this motor is somewhat phenomenal.

LUNCHING WITH A CONTEMPORARY.

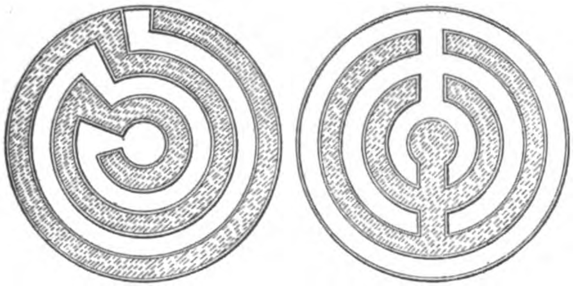
OUR esteemed contemporary, THE ELECTRICAL ENGINEER, celebrated the fitting up of its new offices in the *Mail and Express* Building with a delightful luncheon from twelve to three o'clock on Wednesday, Oct. 26. Messrs. Phelps, Colvin, Martin, Wetzler, Muldaur, Collins and Boughton received the 250 guests of the afternoon, who all complimented the paper on its handsome quarters.—*New York Electrical Review.*

A BIOGRAPHICAL SKETCH OF THE KHOTINSKY ACCUMULATOR.—V.

BY

Capt. A. de Khotinsky

The current density per square centimetre in charging and discharging distributes itself over the whole surface in inverse proportion to the resistance of the electrolyte, which touches said surface. From this it results that at the lower part of the electrode the action is more energetic than at the upper part, and therefore must result in an earlier destruction of the lower part.



Figs. 14 and 15.

To avoid short-circuit by ramifications I enveloped the positive and negative plates with parchment paper and filled the space with sifted river quartz sand. This improved accumulator worked more satisfactorily a longer time and no inner short-circuit existed. After some weeks, however, I observed that the potential commenced to fall. Measuring the potential of several of the cells, I found that some of the cells, at the beginning of the discharge, instead of giving the usual potential difference of 1.95 volts, gave only from 1.8 to 1.85 volts. To my surprise, the dropping off of the potential existed only in such cells in which the spaces between the electrodes had been filled with quartz sand. Closer examination of these cells showed that at the time of the highest charge, in the upper part of the positive plates, the liquid displayed a bright purplish red color which occurred at the time the highest development of gas by the positive plates took place. On ceasing to charge, these colors turned pale and became yellow in the beginning of discharging, and during the continued discharging there were formed, at the upper part of the positive plates, bright yellow crystals which by and by, on contact with air, changed into a brown powder.

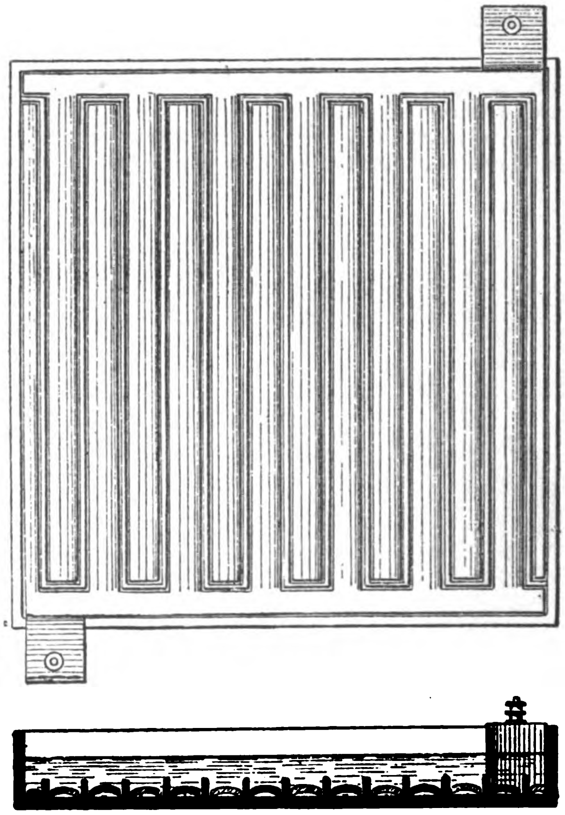
The chemical analysis of the purple red liquid and the crystals proved the existence of iron and showed that they must have originated from combination of iron and acid. The opposing E. M. F. of the iron must also have caused the fall of potential in the cells. The iron must have been reduced from the quartz sand, which always holds traces of iron ore. I learned from this occurrence how exceedingly important it is in making accumulators to use only chemically pure materials.

At that time, it was customary to make the connections between the cells of copper, and the binding screws of brass. In charging the elements these parts were oxidized and converted into lumps much like mushrooms by the acid, and the contact, therefore, became so defective that heating took place. Owing to the heating, the oxide dried and the contact ceased entirely. This led me to make all connections in a battery, of lead only, and to make all contacts exclusively by melting together.

Previous experiments in England with secondary batteries had already caused the thought to arise in my mind to arrange the electrodes in a horizontal position. During my work in Rotterdam this thought was not mature enough to put it into practical use. I was therefore compelled, in the case of the battery first built, to still make use of electrodes in a vertical position. All unsuccessful experiences I had had with vertical plates confirmed me in the adoption of the horizontal arrangement of electrodes to avoid these failures, and for the following reasons:

1. The falling off of active matter from the electrodes can not exist in the horizontal position, because the electrode is put on the bottom of the vessel at the start. 2. Internal short-circuit by the touching of electrodes was impossible, when a partition wall, higher than the electrode itself, separated the positive and negative from each other. 3. Local action cannot exist, because the horizontally formed surface of the electrode is perfectly parallel with the layers, which form the specific weight of the acid. 4. Rapid destruction of the electrodes at only one place, in the vertical position at the lower part, by the flowing in of the stronger acid is unavoidable. In the horizontal position of the electrode this is avoided, because the electrode has its whole surface surrounded with acid of exactly uniform specific gravity.

Figs. 14 and 15 show the different arrangements for horizontal position of the electrodes. The first experiments with cells in a horizontal position I made in hard rubber trays of 25 x 25 x 5 cms. The bottom of these trays I covered with lead 0.6 mm. thick, and this lead I overlaid with spongy lead 4 mms. thick, as shown in Fig. 16 and 16 A. Other trays of the same kind I covered with different kinds of lead oxide instead of spongy lead. These experiments gave the expected good result of laboratory work for primary and secondary batteries.



Figs. 16 and 16A.

When, however, I turned to practical experiments with these cells, many deficiences showed themselves. Thus, when I had to make one of a capacity of only 40 ampere hours per cell it proved necessary to construct a vessel of 80 x 80 x 5 cms. The inconvenience caused by the great size of the vessel led me to form the oxide in thicker layers. The result of this was greater external resistance, while the weight of the active matter was too great in comparison with the surface of contact. I could not discharge this thick layer of oxide in 8 to 10 hours, as was desirable, with a discharge diagram sufficiently horizontal, but it required 18 to 20 hours to discharge the whole capacity.

To remedy this defect I sought to materially increase the contact surface for the same weight of oxide in the given space, and to begin with in the following way: I prepared a frame work for the positive electrodes of perforated lead strips 10 mm. wide, 1 mm. thick and 42 cms. in length, which I soldered together at distances of 3 mm. by means of vertical connecting strips (Fig. 17). I filled the framework with chemically pure crystallized red lead, so that the filling through the holes could unite into one solid mass with the framework.

The negative electrode skeletons were made in a similar way but with this difference, that the lead strips were not punched through and were only ½ mm. thick, and the distance, therefore, amounted to 5 mm. For filling the negative a mixture of litharge and red lead was used.

This accumulator, the dimensions of which were 45 x 45 x 7 cms., contained 10 kilograms of lead and oxide, 4½ kilograms of 10 per cent. acid The weight of the containing cell amounted to 5½ kilograms; consequently the total weight was 20 kilograms. With an 8-hour discharge its capacity was 100 ampere hours, with 10 per cent. drop in potential.

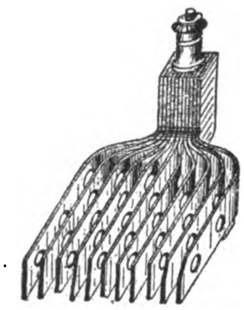


Fig. 17.

While I was occupied with this accumulator, in the beginning of my experiments, for which I made four cells, my company had negotiated with the Frankfort Co. in connection with the Electro-Technical Manufactory, of Cannstadt. A commission from this company, under direction of Prof. Dr. Dietrich, of Stuttgart, came to Rotterdam in November, 1884, for the purpose of examining my new accumulator. Prof. Dietrich was well satisfied with the tests already made, but expressed a desire to make more complete tests with the accumulator.

In the meantime I was more and more convinced of the good quality of my accumulator with horizontal electrodes. I proposed to my company to discontinue the experimental lighting with vertical accumulators, the batteries of which were set up in two boats, and proposed to light one block of houses by means of a combined system. accumulator and dynamo on the same circuit, and to use in that the new horizontal accumulators. This proposition was accepted after Prof. Hospitalier, of Paris, had given his approval and commended it. I put up the block station at Boomjes, in Rotterdam. It was designed for 300 glow lamps, and in March, 1885, it was put in operation.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

At the Institute headquarters, 12 West 31st street, this city, on November 15 at 8 p. m., Dr. J. B. Williams will present a most interesting paper on "Oil versus Air as an Insulating Medium," and make a number of remarkable tests and experiments, not only with oil and air but with samples of insulated wire.

THE USE OF STORAGE BATTERIES IN CENTRAL STATIONS ABROAD.

BY

RECrompton

I have read with interest the leading article on storage batteries in The Electrical Engineer of August 31. As I personally have been responsible for putting in a very large proportion of the storage batteries used in our English central stations I am in a position to correct and to supplement the information furnished to you by your informant. It is evident from his statement that if he did not discover any instances in Europe in which the battery came into use at times when the load became abnormally heavy, it was because he had not pursued his inquiries very far. I could name at least a dozen large central stations where the battery does come into use at the time that the load is heavy. For instance the central station at the Schenkenstrasse at Vienna, which supplies the large theatres, has not sufficient dynamo plant to supply more than one third of the maximum load at times when some of the great scenic changes take place in the Grand Opera. During these short periods of maximum demand frequently three-fourths of the total load is supplied by the accumulators. This station has been at work for nearly eight years and from its commencement has always worked well. The running expenses both in fuel and in maintenance even now contrast very favorably with any other stations on the continent of Europe. Turning to our English stations, if your informant had made careful inquiries at the one which has worked longest, namely that belonging to the Kensington & Knightsbridge Co., at Kensington Court, from which station an absolutely uninterrupted supply of electricity has been furnished since the year 1886, he would have been shown that a considerable slice of the peak of the load diagram during the winter months has been supplied by the batteries. During the summer months we found the most economical mode of working is to furnish the entire load from the accumulators for as many hours as possible and as we frequently can do this from 11 p. m. to 3 o'clock in the following afternoon, we have every object to gain in leaving our accumulators fully charged at the time we stop the running machinery at 11 p., m. so that we arrange not to take any charge from the accumulators during these running hours, But in winter the case is widely different; the hours during which the load is sufficiently light to be furnished from the accumulators by themselves only extend between 1 a. m. and 5 a. m., and for such a short run it is not necessary to start with the accumulator quite full, so that the engineer in charge may, if he finds it convenient to do so, supplement his dynamo plant by drawing from the accumulators during the hours of maximum load. Of course the mode of procedure varies very considerably according to the amount of generating plant in the station, as on this side of the water our central stations are nearly all of them only partially filled with generating machinery to which additions are made from time to time. It follows that as the increase in load gains on the generating plant installed we have to supply more and more of the maximum load from the accumulators; but on the other hand immediately after an additional instalment of generating plant has been put down it may for some months be sufficient to meet the entire load without any aid from the accumulators.

Your informant is quite correct in pointing out that one of the great differences between your American practice and our English practice is that in the latter case our periods of maxim load extend over very short times even in winter. This is due to the fact that such a large number of Londoners dine in their own houses at the same hour, 7.30 to 8 o'clock. Just at this time the whole world dresses for dinner and a large number of bedroom lights are turned on. By 8 o'clock, however, every one has left his bedroom and at the same time the early closing shops switch off their lights so that the maximum load falls by 8 o'clock to a point not two-thirds of its previous value between the hours of 7 and 8. I think this extremely high peak on our load diagrams is principally due to the very large number of private dwelling houses attached to our London central stations. I am informed that you have very similar peaks to load diagrams of various American supply stations, so I think it is extremely probable that these same stations would benefit economically from the use of accumulators as much as we do on this side.

I cannot follow your informant's remarks about the batteries themselves requiring a wonderful amount of care and attention; it is true that in the care of accumulators as in the care of any class of machinery we find it more economical to make a small repair immediately the defect is observed instead of waiting for the defect to develop itself and consequently necessitating a much more costly repair; but it is now proved beyond doubt that the cost of upkeep of accumulators can be quite as small as that on any of the central station machinery. What he characterizes as the care of sick cells has now resolved itself into a very simple matter. It took years of observation and experience to determine the cause of certain cells occasionally losing their capacity and consequently being liable to be reversed and sulphated each time that the battery discharged at its normal rate. Recent research however has shown that this mysterious defect is entirely due to the use of impure sulphuric acid. It is very easily cured as the sulphuric acid can be freed from the impurities which cause the mischief at a very trifling expense; but before this matter was thoroughly understood such cells as contained impure acid did undoubtedly require extra care and attention to keep them in order.

There is one point on which your informant did not dwell so much as he might have done, and that is, that the engineers in charge of central stations containing storage plant are relieved of an immense amount of mental anxiety and worry. None of the accidents to the running machinery which are liable to occur in the very best designed central stations can affect the steadiness of the light. Even the burning out of the armature of a 200 h. p. dynamo when it is supplying one-third of the total load of the station hardly produces a perceptible flicker of the lights if accumulators of sufficient size are used in parallel, whereas without their aid such an accident would make the whole of the lights served from that station jump and oscillate to such an extent as might easily cause a panic and hence an accident in a theatre or place of crowded assembly. There are many other minor accidents that can and do occur in the best central stations and which must always cause flickers in the light unless accumulators are used. We have instances in London of a boiler safety valve being displaced and hence the whole of the steam supply of a central station failing for a period of 10 minutes or so, the whole load being thrown on the accumulators. The lights were maintained with only a slight drop in the volts and this without the accumulators themselves being damaged by the extra demand made on them.

SIGN PAINTING THE CLOUDS.

Mr. Sydney Hodges, of Ealing, England, has succeeded in projecting a large and highly luminous letter on the clouds by means of an invention of his own. This latest application of the electric light was witnessed by himself, his friend Col. Marsh, of the Royal Engineers, and by an assistant engineer of the electrical works at the Horticultural Exhibition.

AUTOMATIC REGULATION OF WATER WHEELS FOR ELECTRICAL WORK.

BY

J. E. Pritchard

In dealing with this question, the most important matter is very often overlooked, viz., the gate rigging of the wheel to be regulated. We very often hear the remark made, that there is no governor sufficiently sensitive to regulate a wheel for electric work. This is a mistake. It is very easy to procure a device that will move the gates rapidly enough, but the difficulty exists in the fact that water, being practically incompressible, it is an impossibility to regulate the flow with any degree of sensitiveness. This point is very nicely covered and made plain in an article in The Electrical Engineer of Sept. 14, 1892, headed, "Governing Water Wheels, a Suggestion and an Inquiry."

In the selection of a wheel for work requiring close regulation, one should be chosen having a gate that tends to close when the water is flowing through it. By having this feature, it will readily be seen that the movement of the gate will be prompt, as there is time lost in taking up back-lash, torsion in gate shafts, etc. It is very important that the gate respond to the slightest movement of the governor within the least possible time. By the adoption of a wheel that possesses this feature, it is a comparatively easy matter to regulate sufficiently close for lighting or textile fabric work.

With electric railway work, I have found it an impossibility to do the work of regulating the wheel with any degree of satisfaction. The difficulty encountered is fully described in the above-mentioned article, and is a very serious one. In dealing with this question at Oswego, N. Y., I overcame the difficulty in a very satisfactory manner, by the introduction of an automatically varied load, which, practically, held the load on the generator constant. It consisted of a rheostat of iron wire of a capacity nearly equal to the gross output of the generators. This rheostat was composed of No. 17 B. & S. (common stove pipe) wire in sections. The resistance of each section was sufficient to allow a leakage of eight amperes at a pressure of five hundred volts.

By the use of an automatic device, these sections were cut in and out of action in proportion to the speed of the generators. With a normal speed, none were in action; as the speed increased, the devices cut in one after the other and at the time the speed was in excess of normal from five to seven per cent., there was the same load (electrically) on generators as when running at normal speed. By the use of this device, which is still in use, the regulation was accomplished in a very satisfactory manner.

The principal objection to using this scheme is, that the same amount of water is used with light load as with heavy load; but as a rule, where water power is cheap enough to make it preferable to steam, there is a surplus of water, and this objection is reduced to a minimum.

I have experimented with a water wheel governor in connection with this device, but as a whole, it has not been satisfactory. With the above described device, I found that all that was necessary was to open the gates to a point sufficient to carry the greatest number of cars to be used for the day. That point once reached, nothing more was required. It was connected in such a manner as not to interfere with the automatic circuit breakers, and in case of a short-circuit, the device came into action and prevented any undue speed.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 203 *Broadway, New York City.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can 'entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinsons only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XIV. NEW YORK, NOVEMBER 9, 1892. No. 286.

In seeking out principles, the simplest instruments and experiments teach more than elaborate ones.—John T. Sprague.

STORAGE BATTERIES IN CENTRAL STATIONS.

PERHAPS in no branch of electric light and power work does American practice so differ from,—or as some contend, lag behind—that in vogue abroad as in the application of storage batteries as auxiliaries to the regular dynamo equipment of central stations. Whether the limited use of batteries in the United States is due to the prolonged litigation, now, happily, ended, or to a distrust of their reliability and endurance, the fact remains that we have been accused by European electrical engineers of neglecting what to them appears as a valuable adjunct conducing to economy in central station work. Our columns have lately contained a number of articles advocating the introduction of such auxiliary batteries, and giving apparently ample reasons in support of the European practice in this respect. It was with some degree of surprise, not to say disappointment, that we learned from a well-known electrical engineer, whose opinion we quoted in our issue of August 31, that while the central station battery plants abroad did good work in carrying the station over the period of very light load, no instance had come under his notice in which the batteries assisted the dynamos during the heavy load period. These batteries, also, it was claimed, required considerable care and delicate handling, and occupied a disproportionally large space, as compared with the dynamo plant. We might also, in this connection, recall the sentiment expressed by Prof. F. B. Crocker, in his recent lecture delivered before the New York Electrical Society, that a small auxiliary engine and dynamo could, in his opinion, be operated more economically, everything considered, than a battery plant.

Our editorial comments made in the issue above referred to, have served to call forth a communication from Mr. R. E. Crompton, of London, who has probably had as long and varied an experience in central station battery work as any electrical engineer in the field. According to Mr. Crompton, it would appear that our informant had based his opinion on too limited an observation, as Mr. Crompton cites several cases in which the batteries do assist the dynamos at the heavy load period. As to the care required by storage batteries, Mr. Crompton's experience leads him to the opinion that if pure acid is used, this item of expense need not exceed that of any other station charge. If then, as would appear from Mr. Crompton's communication, storage batteries are and can be utilized to assist the dynamos over the heavy load, there ought to be a place for them in central station work, wherever the load diagram will sanction their use.

IS THIS THE FIRST GUN?

THE following appeared as an advertisement in the *Boston Herald* of November 1:

THE EDISON ELECTRIC ILLUMINATING CO. OF BOSTON.

NOTICE TO THE PUBLIC.

The United States Court of Appeals for the Second Circuit, a court of last resort, having rendered a decision fully sustaining the claims of Thomas A. Edison as the original inventor of the incandescent lamp, now in common use, the public in general and all present users of such incandescent lamps in particular, whether burning on isolated plants or on the circuits of any other company, are hereby notified that the above company is the sole owner of all such inventions for the city of Boston, and that the sale or use of the same, without the express consent of said company, is hereby prohibited in said city; and further that any such sale or use, without such consent, will render the person or corporation using the same, liable to actions for damages on behalf of this company.

THE EDISON ELECTRIC ILLUMINATING
COMPANY OF BOSTON,
By JACOB C. ROGERS, President.

Nov. 1, 1892, 3 Head Place, Boston, Mass.

It seems not unlikely that a similar "notice to the public" will shortly appear on the part of Edison licensee companies in other towns at an early date, either as public advertisements or as circular notices to consumers. The Edison Electric Illuminating Company of New York, however, disclaims any immediate intention of serving a notice like that of the Boston company.

The General Electric Company disavows responsibility for the Boston advertisement or for any like announcements by other Edison lighting companies; a trustworthy authority in its behalf stating that each local company does as it likes in that regard, and that the above advertisement should not be taken as implying the adoption of a policy by the General Electric Company. The Boston case is an instance of numerous others, where Edison licensee companies are in competition with other local companies having licenses or contracts with the Thomson-Houston Company. In the present case, however, we do not imagine that the officers of the competing company—the Boston Electric Light Company—are filled with any dismal forebodings of a cessation of its business.

SIEMENS' EXPERIMENTS WITH HIGH-TENSION ALTERNATING CURRENTS.

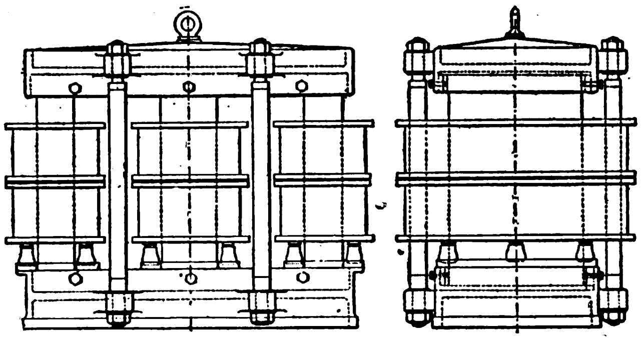
BY

Wm. J. Hammer

Visitors to the Frankfort Electrical Exhibition of 1891 will remember the very interesting experiments shown by Messrs. Siemens & Halske, of Berlin, Germany, with alternating currents of high potential. Two hundred incandescent lamps were seen burning in series; thick sheets of glass were pierced and an arc representing a difference of potential of 20,000 volts was shown. The current employed was produced by a large Siemens alternator, giving an E. M. F. of 2,000 volts which was then transformed up to 20,000 volts.

Messrs. Siemens Bros. & Co., of London, England, in the same year constructed a large transformer capable of giving a pressure of at least 50,000 volts, and during the Naval Exhibition of 1891 repeated many of the experiments made by their confreres in Germany, together with others of a novel and highly interesting character, and subsequently these experiments were shown twice daily at the Crystal Palace Electrical Exhibition of 1892. In the interval Mr. Nikola Tesla had repeated his wonderful experiments with alternating currents of high potential and high frequency before the scientific men of England, at the Royal Institution, and Messrs. Siemens & Co. found it was possible to reproduce some of these phenomena with their apparatus.

The plant used by them at the Crystal Palace consisted of a Siemens W 20 alternator coupled direct to a Willans central valve engine and with the exciter also coupled to the shaft of the alternator; the dynamo had 20 fields and at its normal speed of 400 revolutions per minute gave a frequency of 66.6 complete periods per second. The normal current was 500 amperes, though in the experiments with the "arc" the amperemeter indicated over 600 amperes; the E. M. F. with the full exciting current was 80 volts. A variable resistance in the exciting circuit by means of which the strength of field of the alternator and its E. M. F. could be varied was placed upon the lecture table together with a switch for throwing on or off the exciting circuit which was thus under the control of the experimenter. As an additional precaution switches were inserted in both the primary circuit of the "cable transformer" and the primary of the large transformer.



Figs. 1 and 2.—Siemens High Tension Transformer.

From the alternator the current passed to the primary of a Siemens cable transformer, consisting of a long, flexible, soft iron rope, over which was wound the primary circuit of insulated copper wire; over this was wound the secondary circuit of insulated copper wire and the serving of jute. The windings were put on spirally by means of a cabling machine in the same manner as an ordinary cable is made. The ratio of transformation in the cable transformer was 1 to 30, so that from the secondary of the cable transformer a current of 16 amperes and 2,500 volts was produced. The alternator and cable transformer were placed in the machinery gallery, the latter being suspended in the air and having the appearance of a large steam pipe.

Some 80 yards away, in the Pompeiian Court, the lectures and experiments took place, being in charge of Mr. G. P. Simpson, representing Siemens Bros. & Co. The secondary of the cable transformer was connected to the primary of the large one in the lecture-room by a twin cable insulated with india-rubber. The ratio of transformation in the large transformer was 1 to 20, so that with 2,500 volts in the primary, it was possible to obtain 50,000 volts at the terminals of the secondary. On several occasions the pressure was raised to quite 60,000 volts.

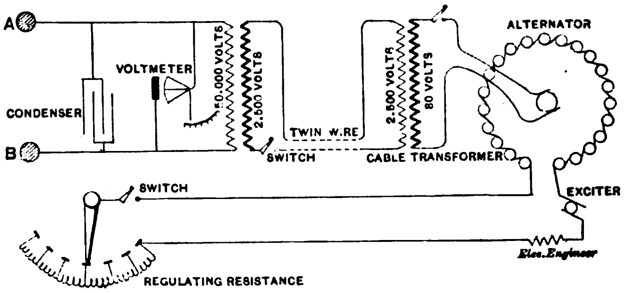


Fig. 3.

The Siemens 130 h. p. transformer is shown in front and end elevation in the accompanying engravings, Figs. 1 and 2.

The magnetic part of the transformer is made throughout of laminated soft iron and comprises three vertical cores, united by horizontal yoke-pieces set into two castings which form the base and cap of the transformer. Each of the castings is furnished with lugs and the whole is firmly held together by bolts passing through them; these bolts are covered with ebonite throughout almost their entire length to prevent any leakage from the windings to earth. In this construction there are two complete magnetic circuits, and as the central core is common to both it has twice the sectional area of either of the others. Each core is surrounded with a primary coil wound directly upon it with a conductor capable of carrying safely 50 amperes, special precautions being taken with respect to insulation.

The secondary winding is wound upon frames which are supported upon porcelain insulators; an air space is left between each primary and the inside of the corresponding secondary giving the latter an air insulation. The ends of the secondary windings on each frame come to terminal blocks mounted on ebonite, so that it is possible to vary the connections of the frames. In the actual experiments all six were connected in series; the extreme terminals were connected to two small brass knobs on ebonite rods standing on the lecture table and to these were joined up the several apparatus used in the experiments. The general arrangement is shown in the accompanying diagram, Fig. 3, where A and B are the two final brass knobs between which the potential difference was produced. Across these knobs there was connected a condenser, which was, however, only used in certain of the experiments, and one of Lord Kelvin's electrostatic voltmeters calibrated for the high potentials used.

In all the experiments, the circuit of the exciter was first closed with all the resistance in; this gave, with the alternator running at full speed, a mean potential difference of 20,000 volts. The resistance was then cut out gradually until the pressure desired for an experiment was secured. For the purpose of exhibiting the arc two carbon rods fitted into brass sockets on top of ebonite rods were placed upon the table, the rods being opposite one another and about 3½ to 4 inches apart; at a pressure of 30,000 volts an arc was formed which could be considerably lengthened. Though carbons were used generally, metal points were found to answer as well.

The arcs shown in the accompanying illustrations, Figs. 4 and 5, were about 3 feet long, each side being 18 inches long. The cuts shown are made from instantaneous photographs taken by the light of the arcs themselves, and I wish to call especial attention to the striations in the flame and to the spiral character of the arc which should throw some light upon the recent discussions[1] in The Electrical Engineer. The spiraling is very clearly shown in these beautiful photographs, and it is exceedingly interesting to note, particularly in Fig. 3, that the flame from the right-hand electrode is a right-hand spiral, while that of the left-hand electrode has a left-hand spiral. The halo shown about the right-hand electrode in Fig. 4 is due merely to a higher temperature of the carbon at that pole; in Fig. 10 they will be seen to be alike.

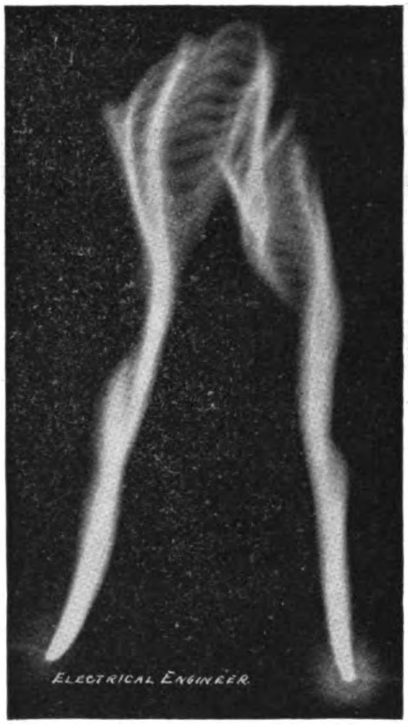

Fig. 4.

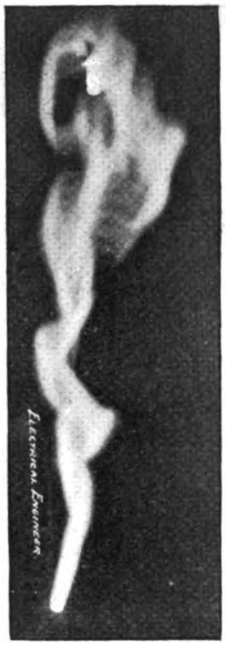

Fig. 7.

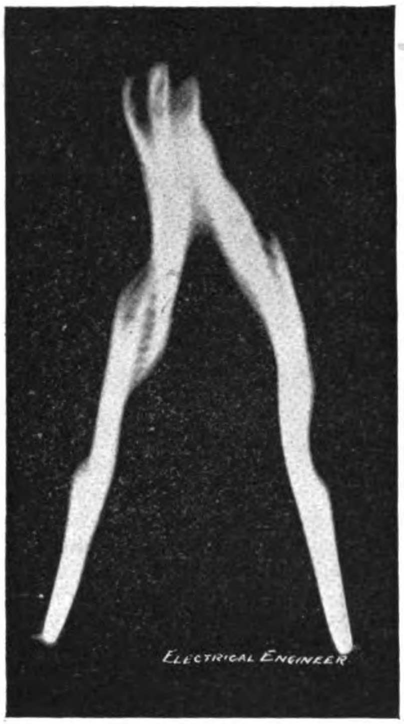

Fig. 5.

In some of the experiments I saw in both Siemens' and Swinburne's experiments at the Crystal Palace the arcs from the two electrodes were of markedly different color, and I heard a number of people explaining that this was due to phenomena of the high-tension currents, which give the arc at each pole a distinctive color. The cause, however, was due solely to the employment of different kinds of carbons as the electrodes. Accompanying the arc one hears a loud humming sound, which, it is interesting to note, is the same in pitch as that given out by the alternator, and probably the striations bear a close relation to the periodicity of the current. The wave-like character of the striations is particularly noticeable in Fig. 4; they were always present. In Figs. 6 and 7 the electrodes are shown placed one above the other, when the arc can be made somewhat longer and the striations sometimes seen more clearly.

When the terminals were connected by some badly conducting substance, such as a long strip of wood, it was easily traversed and soon set on fire. Substances which we have been accustomed to consider good insulators became excellent conductors with a current of such high potential. A plate of slate an inch thick, with an electrode on either side acted like a miniature volcano, some of the silicates being fused and thrown out like lava.

In another interesting experiment a small tank containing water was connected to one terminal, and a metal pan below connected to the other; on opening the top bright flashes of lightning darted through the falling drops, accompanied by snapping sounds and formation of steam, and at times the arc would leap across directly instead of passing through the water. Perhaps the most beautiful effect was produced by interposing a sheet of glass 2 to 4 millimetres thick between the electrodes. The glass was placed upon an insulated support, and at its centre on the back side was placed one terminal ending in a flat brass disc, the other terminal from the transformer which carried a metal rod being placed opposite on the front side of the glass. The rod was arranged to carry a conical point, a sphere, or disc, as desired. The nature of the discharge did not vary very greatly with changes in the form of the upper electrode; the most striking effects were, however, produced by a disc back and front. These are shown in

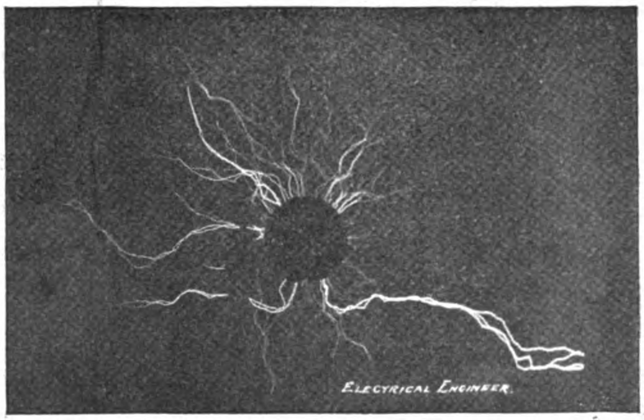

Fig. 8.

---

[1] See The Electrical Engineer, July 20 and Sept. 14, 1892.

Figs. 8 and 9, also reproduced from instantaneous photographs. In the former an E. M. F. of 35,000 volts was used; both surfaces of the glass were covered with innumerable purplish blue lines.

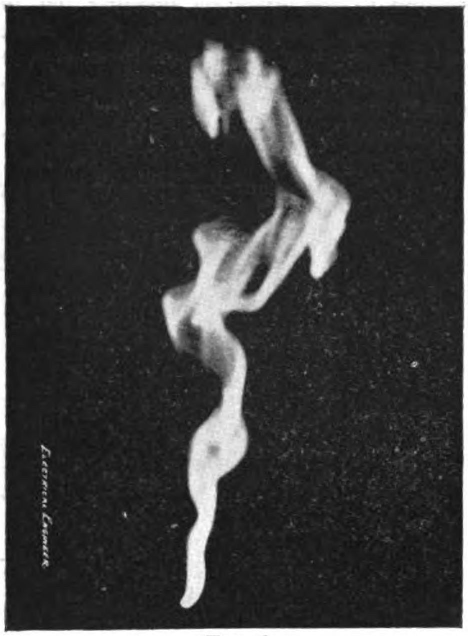

FIG. 6.

It is interesting to note, that while in the photograph these appear as single threads radiating from the electrode, when viewed by the eye, owing to the persistence of vision, these threads seem mixed up in a most intricate network, changing with marvelous rapidity. Upon raising the pressure still higher, white flashes begin to pass completely around the glass from one electrode to the other accompanied by a loud report. In Fig. 8 one such flash is shown. In Fig. 9 the flashes in great number are shown passing around the glass; they are blinding, and so loud as to be unpleasant to the ear. This photograph was taken when the E. M. F. had reached 45,000 volts; the shadow just below that of the brass disc is caused by the ebonite rod. As the plate is of glass the flashes on both sides are visible, and at the lower edge is shown one loop or flash dying out.

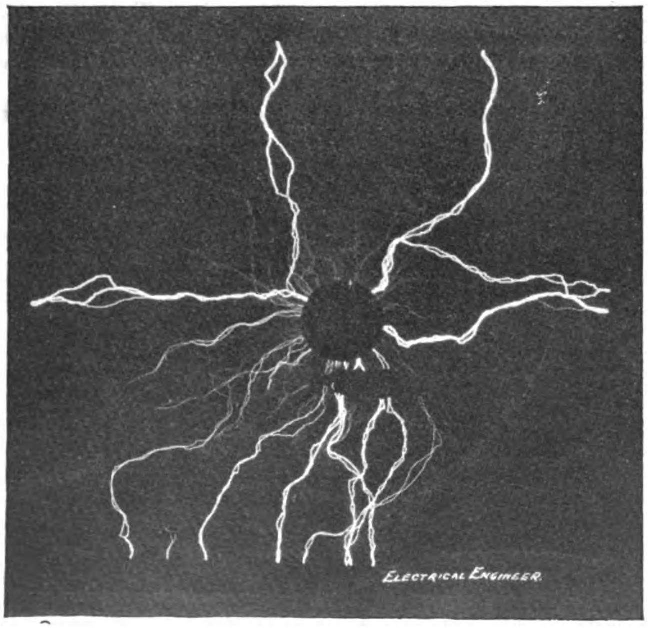

FIG. 9.

After 45,000 to 50,000 volts have been on for periods depending upon the thickness of the glass, the insulation gives way, and the glass, which has been growing constantly hotter and hotter, shows a small hole opposite the periphery of the disc electrode; but upon shutting off the current it was always found that the molten glass had closed the hole up again. Sometimes a circular crack would start from the hole and small cracks would radiate therefrom, breaking the glass into a thousand pieces. Sheets of ebonite, slabs of paraffine wax and marble behaved in a manner similar to the glass.

A most practical demonstration of the high E. M. F. atattained was shown by sending the current from the secondary directly through a bank of 500 16 c. p. incandescent lamps joined in one series; each lamp required 105 volts and at full candle power, as shown, the E. M. F. must have been 52,500 volts. The current required for the lamps used was 0.58 ampere, so the total electrical energy represented in the bank was 40 h. p. The transformer had, however, a capacity for four times this load, viz., two amperes at 50,000 volts. The breaking of one or even a dozen lamps did not affect the rest, as the current arced across the terminals. Comment was caused by the constant vibration of some of the filaments but whether due to the current or to a mechanical cause was not demonstrated. In the above-mentioned experiments considerable power was employed and the circuit was in all cases completed.

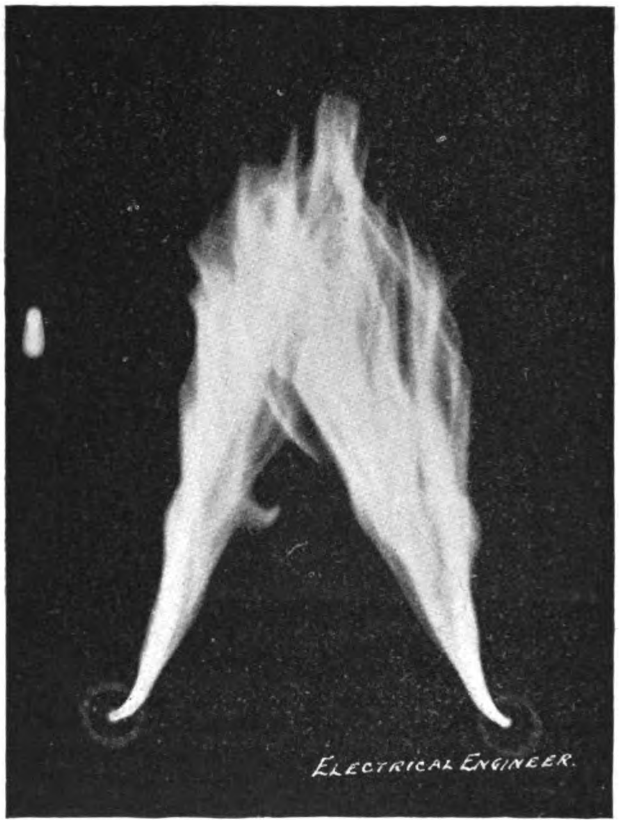

FIG. 10.

Further experiments were conducted by Messrs. Siemens' representative, Mr. Simpson seeking to reproduce some of the results Mr. Tesla obtained, when there was no complete circuit. In these experiments only 66 complete periods per second were employed and a potential difference of 50,000 volts. Two copper wires, either bare or insulated with cotton, were stretched parallel to each other in one horizontal plane about eight inches apart between four ebonite rods, the wires being 10 to 12 feet long. The wires were connected direct to the terminals of the secondary, no means being used to increase the electrical oscillations. When the circuit was closed the wires became luminous in the dark, not throughout their length, as Tesla showed, but as if beads were strung on the wires; these were probably the nodal points referred to by Tesla. Frequently the two wires would vibrate bodily, like a harp string, such vibration being set up by the electrical oscillations and not by mechanical means; perhaps the lamp filaments, if the degree of vacuum and delicacy of the filament are suitable, vibrate from the same cause.

Two large rings of wire three feet in diameter showed similar phenomena of nodal points. These electrical oscillations passed through the air a considerable distance, as shown by the illumination of a "Tesla tube" that is, a vacuum tube without electrodes 3 feet long and exhausted to about one millionth of an atmosphere. The tube, when placed near the wires became filled with a bluish glow and when a sheet of tin was attached to one terminal, the other being insulated, the Tesla tube glowed anywhere in the neighborhood of the metal sheet. In dry weather the glow would continue at a distance of 5 or 6 feet; in a moist atmosphere the distance was from 2 to 3 feet and during the prolonged and severe thunderstorm of June 28, 1892, the tube would not glow in any position.

One other Tesla effect shown at a frequency of only 66 was holding a tube in the left hand at such a distance from the terminals that no glow was visible and on touching one terminal with the right hand the tube became filled with the usual glow, the electrical oscillations being transmitted through the experimenter's body; the only effects appreciable were a slight shock in the right arm and a distinct rise in the temperature of the whole body.

In conclusion I wish to call attention to the photograph shown in Fig. 10. This was taken by Messrs. Swinburne & Co., of London, who have been conducting experiments recently in currents of high potential and high frequency. They also gave exhibitions at the Crystal Palace Electrical Exhibition of 1892, following the same general lines as those of Messrs. Siemens & Co., but employing transformers immersed in oil and producing, so they claimed, an E. M. F. of 150,000 volts, the photograph shown represents an arc produced (?) at that potential. In the absence of any testing instruments capable of indicating over 75,000 volts or even a bank of lamps which would perhaps be even more reliable evidence, the potential attained can only be surmised. Their experiments were however most interesting.

INSULATED ELECTRIC CONDUCTORS.[1]—XIII

BY

James Bowstead Williams M.E.

In the last article a brief description only of braiders and the manufacture of painted wires was given, but as this class of wires forms a considerable proportion of the insulated conductors now in use, and their manufacture deserves more care and attention than it usually receives—for if weatherproof wires were better insulated there would not be *quite* so many accidents of one kind or another when the ordinary weatherpoof wires carrying high tension currents come in contact with grounded bodies—the writer proposes to enter into the details of the production of such wires. In addition to the painted wires, there will be added some examples of wires having dielectrics formed of other materials besides fibre and paint, and which may also be properly classed among weatherproof wires.

Before entering into the details of manufacture it will be well to consider the substances which constitute the dielectrics of the wires, fibre and paints.

The fibrous material may, for convenience of description, be considered as forming the framework of the dielectric. It also acts as an absorbent of the insulating compositions, and retains them in contact with, and in position upon, the wire. Paint, as well as other material which can readily be applied while in a liquid state, without some means for securing it to the wire would soon become detached and useless, even though many layers or coats had been applied one upon the other, and each allowed to harden before the next was applied. The fibre should be strong, soft, and flexible, and the yarn or thread formed of it be of uniform thickness. It should be free from all gummy and other foreign matters, and absorb liquids readily, so that all of the interstices of the fibrous covering may be completely filled; and the less fuzz projecting from the separate layers of braid, the better for the insulation. Good, fresh, clean cotton combines these qualities to a high degree, and is probably the best and cheapest fibre now at hand. Silk would be a most excellent fibre for the layer next the wire, but its high cost prohibits its use. Jute fibre is too coarse and brittle for braided layers, and will not lie close. Cotton, silk and jute are very hygroscopic, and great care is required to keep them dry during the manufacture of dielectrics. Insulating paints differ from common paints in many respects, both in their application and composition. In the following tabular statement will be shown the chief points of similiarity and difference; and these will be followed by explanatory remarks.

Insulating Paints.	*Common Paints.*
1. Must be flexible.	1. Need not be flexible.
2. Should harden quickly.	2. Should harden quickly.
3. Must contain little or no lead or other conducting material.	3. May contain a large amount of such material without injury.
4. Should contain little or no volatile solvents.	4. Usually contain such solvents.
5. Are applied upon rough or uneven surfaces.	5. Are applied upon smooth and prepared surfaces.
6. Do not need a gloss or finish.	6. A gloss is nearly always required to improve their appearance.
7. But one application should be required for each layer.	7. Two or more coats are usually required to form a covering.
8. May contain dryers.	8. Usually do contain them.
9. A soft and tough finish desirable.	9. A hard finish desirable.
10 Must be a *chemical* compound, and contain no precipitates.	10. Often a mechanical mixture only.
11. Must contain no water in the solvent.	11. Water often forms a portion of the solvent.

It is to be understood that the statements just made refer to the best kinds of insulating paints and not to *protecting* paints.

The explanatory remarks will be numbered to correspond with the statements in the table.

Remark 1.—No paint should be used for insulating wires which will not form a layer more or less flexible, when dry. In practice we often find paints which are hard and brittle. Such paints, while they may possess good insulating properties at first, soon got full of cracks if the wires are bent, or if they are subjected to changes of temperature. Far better have an insulating covering into which a tie or binding wire may sink a little than a rigid one which will get full of cracks and *therefore* full of moisture.

Remark 2.—While it is not absolutely necessary that paints should dry rapidly, it is desirable that they should do so; and, in all cases, painted wires should be kept in a warm dry place until the coverings are dry. No painted covering should be allowed to dry after the wires are strung on poles. The writer spent considerable time in the manufacture of painted wires, and found that, in every case, when paints not thoroughly dry are exposed to the atmosphere *moisture goes in as solvent goes out.* The reason for this is that as the solvent evaporates, minute air spaces are formed in the covering; and as there is no way by which these spaces can be filled with insulating material after the wires are suspended, moisture necessarily enters them by capillary attraction. Unfortunately, for electricians, the most rapidly drying paints are not the best insulating paints.

ELECTRIC RAILWAY DEPARTMENT.

THE RESISTANCE OF RETURN CIRCUITS IN ELECTRIC STREET RAILWAY PRACTICE.

BY

R. C. Warner

In general electric street railway practice, and more especially where cars are operated at considerable distances from the power station, the securing of a circuit of the lowest possible resistance consistent with economical construction becomes a matter of particular importance. For the overhead or positive side of the circuit the problem is a comparatively simple one, it being merely a question to what extent increased outlay for feeders is compensated for by increased efficiency of transmission. The return circuit through the rails and earth presents, however, an entirely different set of conditions, varying with the location and the seasons and dependent upon the character of the soil, nature of the construction, cleanliness of tracks, etc. So far as the constructing engineer is concerned, the problem is mainly one of efficient bonding. The question, then, is, What *is* "efficient bonding," and how may it be most economically secured?

This question has received a variety of answers from engineers, but accurate data as to the relative value of the various methods employed is extremely scarce. It was with a view of securing, if possible, some definite information on this subject that the writer jointly with Mr. G. L. Thayer, undertook, at the instance of a well-known firm of engineers, a series of tests, the results of which are here given.

Portions of the tracks in use in Utica, Rochester and Buffalo were included in the tests, the object being to determine the resistance in ohms of known lengths of track representing different methods of construction as regards bonding, etc. The method first tried for determining this resistance was that of the Wheatstone bridge. A portable bridge and battery were taken to Utica, and during the night, after the machines had shut down, the feeders were cut out, the trolley wire and tracks connected at one point and the bridge put in at a known distance, the length of track and trolley wire forming one arm. The idea was to determine the resistance of this circuit in the ordinary manner and then deduct the known resistance of the length of trolley wire to find that of the tracks. Owing, however, to a counter E. M. F., due to connections and grounds, it was found impossible to balance the bridge, and this plan had to be abandoned.

A fall of potential method was next tried with better success and was used in the subsequent tests. The Utica power station is located at some distance from the lines operated near the tracks of the R. & W. R. R. Advantage is taken of the proximity of these tracks to secure a return circuit from one portion of the road down town, the machines being connected direct to the tracks by No. 0 copper wire. The top wire of a barb wire fence running parallel with the railroad was connected to the rails as a potential wire at a known distance from the station, and a Weston voltmeter was used to determine the drop through this length of track, the current being read from a Weston ammeter placed between the machines and the track.

The use of a cut-out feeder as a potential wire, which had been intended at Rochester and Buffalo, was prevented by the fact that these roads operate all night with but a short stop, and it became necessary to run a special line of iron wire for each piece of track tested. The extreme end of a line was tested in each case, where the cars run at long enough intervals to leave the track clear for some minutes at a time. The iron potential wire was connected to the track by filing out a rail joint and wedging the wire against the end of the rail. A No. 5 copper wire bound to a fishing pole was used to take current from the trolley wire, and a convenient adjustable resistance was made by fastening one copper terminal plate on the inside of a wooden bucket filled with water, and suspending another from a slide on the top of the bucket. The capacity of the resistance was increased as desired by the use of salt. A Weston voltmeter of high resistance was used in every case, except the first day on Park avenue, Rochester, when a Weston instrument of but 597 ohms resistance was used. A correction must, therefore, be made in this case, for the resistance of the potential wire, as follows:

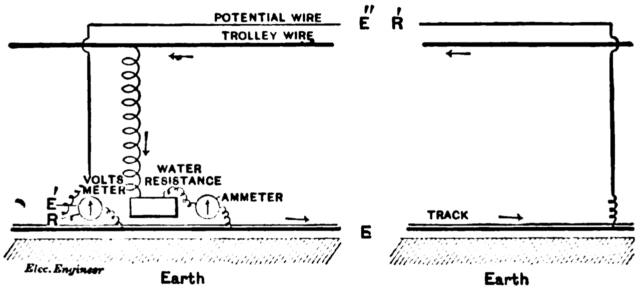

Diagram of Testing Method.

Let E = drop through the 3,000 feet of track tested;
" E' = " " " voltmeter;
" E'' = " " iron potential wire;
" R = resistance of voltmeter = 597 ohms;
" R' = " potential wire = 110 ohms;
" C = current flowing through voltmeter.

$$E = E' + E''; \; C = \frac{E'}{R}; \; E'' = CR' = E'\left(\frac{110}{597}\right)$$

$$E = E' + E'\left(\frac{110}{597}\right) = E'\left(1 + \frac{110}{597}\right) = E' \times 1.1845.$$

The observed drop then, multiplied by this constant gives the actual drop in the track.

In the case of the Lake Avenue Line, Rochester, a nearly constant counter E. M. F. was found. The main circuit was, therefore, broken, and readings of the counter E. M. F. taken before and after each regular reading, and the amount of this counter E. M. F., added to the observed E. M. F., gave the actual drop in the rails due to current flowing.

The tracks tested were as follows:

A.

Location: Utica, near power station. 690 feet single track built of 60 lb. T rails, joined by angle bars and laid on sawed ties. No bonding. Condition of tracks, June 8, dry and hot at rail joints. Time, 10 a. m.

B.

Location: Park Avenue Line, Rochester, from car barns West. 3,000 feet double track, built of flat rails, 60 lbs. per yard, set on chairs. Bonded with one No. 3 galvanized iron wire, or two No. 6 galvanized iron wires "and other wire on hand at the time." Wire soldered and riveted to rails. No continuous wire. Rails cross-bonded with iron wire every 200 feet. Tracks cross-bonded only by the switches at and near barns, which, apparently, answered the purpose of cross-bonds very well, as the fall of potential was the same through both tracks. Length of time in use, two months. Condition of tracks, June 28, dry; June 30, very wet, the test being made during a heavy rain. Time, 11 a. m.

C.

Location: Lake avenue, Rochester, from city limits south. 3,270 feet single track, built of 40 pound T-rails, laid on sawed ties, no chairs. Bonded with one No. 3 copper wire riveted to rails. Continuous wire No. 3 copper is run inside each rail and a soldered strap connection made with each bond wire; rails cross-bonded every 200 feet. The tracks are on opposite sides of the street inside the curb, some 60 feet apart, and are not connected in any manner near this point. The track tested on one side of street may, therefore, be safely called single track. Length of time in use, two years. Condition of track June 30, wet. Time, 4 a. m.

D.

Location: End of Tonawanda street, Buffalo. 4,110 feet double track, built of 60 pound groove rails set on chairs. Bonded with one No. 3 copper wire, soldered and riveted to rails. Continuous wire No. 3 copper is run inside each rail, and a soldered strap connection made with each bond wire. Rails are cross-bonded every 60 feet; tracks cross-bonded every 90 feet. Length of time in operation, about one year. Condition of tracks July 2, dry. Time, 1 p. m.

E.

Location: Line running from Buffalo to Tonawanda. Connects with Tonawanda street line at city limits. 3,810 feet single track, built of 45 pound T-rails laid on sawed ties. Bonded with two No. 4 galvanized iron wires, soldered and riveted to rails; no continuous wire. Rails are cross-bonded every 60 feet. Length of time in operation, about one year. Condition of tracks July 2, dry. Time 3 p. m. No very heavy currents could be used with this track owing to the limited capacity of the station, the cars being operated by one 120 K. W. machine.

The accompanying tables give the results of the observations.

28	44	1.0	.0228
29	47	1.0	.0213
30	53	1.05	.0198

Mean = .01982 ohm

Resistance = .004815 ohm per 1,000 feet.
" = .0254 " " mile double track.

The resistance has in each case been reduced to ohms per mile double track, the assumption being made that the resistance of two tracks in parallel will be half that of either one, which is very well borne out by a comparison of the results obtained. A consideration of the conditions of the different pieces of track tested affords an explanation of the slight differences of resistance for tracks of similar construction. Track "B" shows a resistance of .0797 ohm when dry, as compared with .0577 ohm for track "E," the method of construction being similar with the exception that "B" was bonded with one No. 3 wire, two No. 6 wires and "other wire on hand at the time," while the Tonawanda line, "E," was bonded throughout with two No. 4 wires, the wire used in both cases being galvanized iron. The difference in favor of the more thorough bonding is over 27 per cent. It will be noticed that the more lightly bonded track has a 60 lb. rail, as compared with a 45 lb. rail for the track of lower resistance. The construction of tracks "C" and "D" in Rochester and Buffalo respectively, is very similar and the resistance proves to be less in the case of the former, which was very wet when tested. It happens in this case again that the lighter rail is in the track of lower resistance. Comparison of the results for the two days on Park avenue track "B," shows that the resistance is some 10 per cent. less when the tracks and earth are wet.

TRACK E.

3810 Feet. Single Track. Bonded. *No Continuous Wire.*

No.	*C.*	*E.*	*R.*	No.	*C.*	*E.*	*R.*
1	15	1.1	.0735	13	25	1.9	.0760
2	15	1.0	.0669	14	25	2.1	.0840
3	15	1.1	.0735	15	26	2.1	.0809
4	17	1.6	.0942	16	29	2.0	.0609
5	19	1.9	.1000	17	32	3.0	.0940
6	18.5	1.7	.0920	18	35	2.8	.0890
7	20	2.0	.1000	19	31	2.7	.0940
8	21	1.9	.0950	20	33	2.8	.0850
9	20	1.6	.0800	21	34	2.6	.0765
10	21	1.7	.0810	22	34	2.6	.0765
11	24	2.1	.0875	23	33	2.7	.0817
12	25	1.9	.0160	24	34	2.7	.0795
						Mean =	.0832 Ohms.

Resistance = .0218 ohms pr. 1000
" " .1154 " " miles single track.
" " .0577 " " " double "

Taking results representative of the three general cases for comparison we have:

"A." Resistance of unbonded track (double) per mile = ...	.7675 ohm.
"E." Resistance of double track bonded and cross-connected with *iron* wire *non-continous* = ...	.0577 ohm.
Resistance being only 7.5 per cent. of A.	
"D." Resistance double track bonded and cross-connected with *copper* wire, *continuous wire*, = ...	.0254 ohm.
Being a reduction of 56 per cent. from "E," due to *copper* and continuous wire.	

That weight of rail does not enter appreciably as a factor in the resistance of the return circuit is shown conclusively by a computation of the resistance due to bonds alone. In case "D," taking the average length of a bond as three feet, 176 bonds per mile, there is, roughly, 530 feet of bond wire per mile for each rail: In one mile of double track then, there are eight No. 3 wires in parallel, four of them 5,280 feet in length, and four 530 feet, the resistance of which proves to be .0236 ohm.

Case "D."—Total resistance of tracks, *tested*	.0254	ohm.
Resistance of bonds and continuous wire *alone, computed*.....	.0236	"
Difference....................	.0018	"

Similarly for case "E."

Total resistance of tracks, *tested*...........	.0577	ohm.
Resistance of bonds *alone, computed*......	.0556	"
Difference.....................	.0021	"

From this it will be seen that it is possible to compute within a few per cent. the actual resistance of the return circuit with *any* proposed method of bonding, etc., as readily as may be done for the overhead construction.

That the use of a continuous wire with each rail in addition to bonds, commonly recommended as "best construction," is not only much more expensive but also considerably less efficient than thorough bonding alone, may be readily proven. Taking for instance case "D" above, suppose that instead of *one* bond of No. 3 copper at each rail joint with continuous wire inside rail, there be used *two* bonds of No. 3 copper *without* continuous wire. Assuming as before an average length of 3 feet per bond, there would be for double track construction per mile eight No. 3 wires 530 feet long in parallel, with a resistance of .013 ohm. Allowing for resistance of rails and connections .002 ohm, the total resistance of one mile double track = .015 ohm. The resistance with continuous wire instead of additional bond (see "D") was .0254 ohm, or .0104 ohm *more* than in the case assumed. The length of No. 3 wire required per mile double track for construction "D" would be

Continuous wire............................	21,120	feet.
Bonds..	2,120	"
Cross-bonds.....	1,240	"
Total........................	24,480	"

or 3,898 pounds of copper, at 14¼ cents per pound, costing $555.47; while for the assumed construction it would be

Bonds..	4,240	feet.
Cross-bonds..........	1,240	"
Total.............	5,480	"

or 872 pounds, costing $124.26.

The change amounts in substance to cutting out four pieces of wire 4,750 feet in length and substituting for them rail of practically unlimited carrying capacity effecting a reduction in resistance of 41 per cent. and a saving in cost of copper for the return circuit of over 75 per cent. The possible saving would of course be considerably greater in the case of roads using No. 1 or No. 0 continuous wires, and would seem to be well worthy the consideration of street railway managers and constructing engineers.

ELECTRIC RAILWAY WORK AT TROY, N. Y.

THE consolidation of the Troy & Lansingburgh and Troy City railways, can only be effected by a lease, as the purchase of the *entire* stock of the Troy & Lansingburgh Railroad is barred, except under a tedious and expensive legal proceeding. Some 140 shares of the stock are still held by estates and persons absent from the country, who cannot be reached at present. In the case of the estates in progress of settlement and held by administrators in trust for minor heirs, nothing in the matter of purchase can be effected, as it would require months to pass the judicial procedures necessary to obtain the stock in question. Hence the shortest way out of the difficulty is said to be a lease of one road to the other, guaranteeing a certain dividend to the stockholders, and as the new corporation holds nearly all the stock of both companies it will be readily seen that any dividends derived from the leasing of the various roads, under the present control of the Troy & Lansingburgh directorate, will be divided among the stockholders in the new corporation, less the amount due the heirs and holders of old stock on the earnings of the particular branch of road so leased.

The Troy City Road is progressing slowly with the River street power house, having at present but one boiler set in position, while the heavy stones for the engine and dynamo foundations are on the ground. The house is at present used only as a car storehouse, power being amply supplied from the Division street power house of the Troy and Lansingburgh road.

A POSTAL STREET CAR SERVICE FOR ST. LOUIS.

FOR two years, Postmaster Harlow has been endeavoring to utilize the street cars in the delivery of mails, and his efforts have at length proved successful. The St. Louis and Suburban Line will run a regular mail car from its eastern terminus to Cabanne. The car is fitted up with mail racks and is constructed especially for the service required. It will deliver mail at the substations on its line. The system will be extended to other street railway lines.

RAILWAY FENDERS ON THE WEST END RAILWAY, BOSTON.

Acting at the request of the Massachusetts Railroad Commission, President Henry M. Whitney, of the West End Street Railway, appointed a commission to recommend a form of fender for use on the cars of his company. The commission consisted of Messrs. Thos. C. Clarke, C. E. A. Bartlett and Geo. F. Swain.

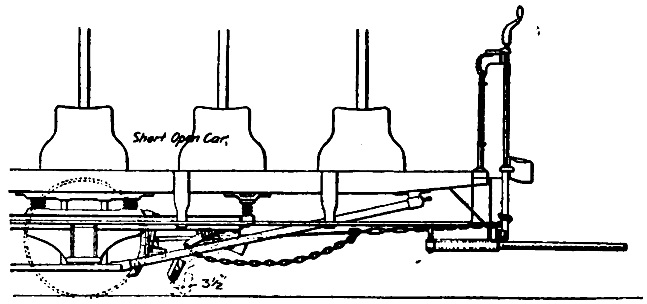
The commission in their report just published state that no less than 211 fenders were presented for examination by plan, model or description. It was found upon examination that all the fenders which were brought to the attention of their company could be divided into three classes, viz.:

A. Buffers which soften the blow given by the car to the person, and pick him up in a net. B Platforms which project beyond the dashboard of the car, and upon which a person could leap, or, standing up, could be caught and carried along. C. Fenders which are placed below the car platform, and whose object is to push along a body lying down upon the tracks, and prevent it from getting under the wheels.

After careful examination of all the devices, it was decided to make experiment with certain ones upon dolls or dummies made, as nearly as possible, of the size, shape and weight of a man, a woman and a child; 43 fenders were, therefore, constructed of full size, and attached to the cars of the West End Company, and experimented with.

Several different kinds of fenders were also attached to cars in regular service; and the commission examined written evidence upon the use of fenders in Kansas City, Cleveland, Rochester and other places.

After more than a year's experimenting with the various devices submitted the commission recommends the adoption of the "Cleveland" platform and buffer, the invention of Mr. Thos. L. Johnson, president of the Cleveland City Railway Company, in combination with a movable fender invented by Mr. L. J. Hirt, master mechanic of the West End Street Railway. Both arrangements are shown in the accompanying engraving.



Car with Cleveland Platform and Buffer and Hirt Fender.

The Cleveland platform and buffer has been modified by the officers of the West End Company, to enable it to be slid under the cars, or under the rear of any car, when it is not in use.

In the type of fender submitted by Mr. Hirt the turning of the brake handle first applies the brake, and then lowers the fender down to the track. The action may be made so quick, however, that the two movements appear nearly simultaneous. This device has no parts that would seem liable to get out of order. It has shown itself, under test, at least as efficient as any other fender. Its operation insures the maximum safety to a body lying on the track, and it imposes no additional duty or responsibility on the motorman in addition to those he now has.

Preparations are being made for equipping all the West End cars with the above described fenders.

STREET RAILWAY BLOCK SIGNAL SYSTEM AT ROCHESTER, PA.

An electric block system is in use on the Rochester, Pa., Electric Railway, a single track line about four miles in length. At each passing siding is located a single box containing two groups of lamps, each group consisting of three lamps of 16 c. p. each. These lamps are wired in series of six, the three lamps in the upper half of one box being connected directly with the three lamps in the lower half of the next box about 4,000 feet away. They are supplied with current from the trolley wire, by a No. 21 galvanized iron wire, in order to get the resistance necessary. Each box is equipped with two three-way switches for turning off the lights, or turning them on as the car enters the section. The cars going in one direction are blocked by lamps burning in the upper half of the boxes, and in the other direction by lamps burning in the lower half of the boxes.

ELECTRIC RAILWAY LITIGATION.

A circular issued by the General Electric Co. gives a list of electric railway suits in which it is interested and which are likely to be pushed. The suits enumerated are as follows:

1.

Thomson-Houston Electric Co.
vs.
Elmira and Horseheads Railway Co.
Circuit Court of the United States for the Northern District of New York.

Subject: *Under Running Trolley.*

Patents.

No 403,801—C. J. Van Depoele, May 20, 1889, for *Cross-Suspension for Trolley Wire.*
No. 424,880—C. J. Van Depoele, March 25, 1890, for *Cross-Suspension for Trolley Wire with Cross-Wires Under Tension.*
No. 424,695—C. J. Van Depoele, April 1, 1890, for *Trailing Switch, Switch Plate with Ribs, Trolley Wheel Fender.*
No. 467,448—C. J. Van Depoele, January 19, 1892, for *Broad Patent for Under Running Upward Pressing Contact Trolley.*

2.

Sprague Electric Railway and Motor Co.
vs.
Fitchburg and Leominster St. Ry. Co.
Circuit Court of the United States for the District of Massachusetts.

Subject: *Electric Motor Trucks.*

Patents.

No. 324,892—F. J. Sprague, August 25, 1885, for *Motor Sleeved on Axle at one end and Spring Supported at the other end.*
No. 406,600—F. J. Sprague, July 9, 1889, for *Motor Sleeved on Axle at two points.*
No. 424,436—F. J. Sprague, March 25, 1890, for *Individual Motors for Separate Axles.*

3.

Sprague Electric Railway and Motor Co.
vs.
Fitchburg and Leominster St. Ry. Co.
Circuit Court of the United States for the District of Massachusetts.

Subject: *Duplicate Controller Switches at opposite ends of Car, Reversing Motor and Regulating Resistance of Motor Circuit.*

Patent.

No. 481,739—F. J. Sprague, August 30, 1892.

4.

Thomson-Houston Electric Co.
vs.
Wakefield and Stoneham Railway Co., Chas. Woodward and M. E. Clemens.
Circuit Court of the United States for the District of Massachusetts.

Subject: *Trolley having Constant Pressure with Pole at Varying Angles.*

Patent.

No. 394,087—C. J. Van Depoele, December 4, 1888.

5.

The Thomson-Houston Electric Co.
vs.
Pittsfield Elec. St. Ry. Co., *et al.*
Circuit Court of the United States for the District of Massachusetts.

Subject: *Arched Suspenders for Electric Railway Trolley Wires.*

Patents.

No. 393,317—C. J. Van Depoele, Nov. 20, 1888.
No. 396,311—C. J. Van Depoele, Jan. 15, 1889.
No. 396,312—C. J. Van Depoele, Jan. 15, 1889.

6.

The Thomson-Houston Electric Co.
vs.
Pittsfield Electric Street Ry. Co., *et al.*
Circuit Court of the United States for the District of Massachusetts.

Subject: *Lightning Arrester.*

Patent.

No. 321,464—Elihu Thomson, July 7, 1885.

7.

Edison Electric Light Co.
vs.
Glens Falls, Sandy Hill and Fort Edward Street Ry. Co., *et al.*
Circuit Court of the United States for the Northern District of New York.

Subject: *Constant Potential Regulation by a Compound Dynamo.*

Patent.

No. 264,668—T. A. Edison, Sept. 19, 1882.

8.

Thomson-Houston Electric Co.
vs.
Elec. Merchandise Co., W. R. Mason and A. H. Englund.
Circuit Court of the United States for the Northern District of Illinois.

Subject: *Overhead Switches.*

Patents.

No. 393,278—C. J. Van Depoele, Nov. 20, 1888, for *Switch and Crossing.*
No. 396,313—C. J. Van Depoele, January 15, 1889, for *Adjustable Switch and Crossing.*

9.

Thomson-Houston Electric Co.
vs.
Elec. Merchandise Co., W. R. Mason and A. H. Englund.
Circuit Court of the Unites States for the Northern District of Illinois.

Subject: *Arched Suspender and Pull-off for Trolley Wires.*

Patents.

No. 393,317—C. J. Van Depoele, Nov. 20, 1888, for *Arched Insulator Holder.*
No. 396,311—C. J. Van Depoele, Jan. 15, 1889, for *Single Arched Insulator Holder.*
No. 396,312—C. J. Van Depoele, Jan. 15, 1889, for *Arched Insulator Holder with Adjustable Ear.*

PROTESTS IN BUFFALO AGAINST LIMITED SPEED.

The Buffalo, N. Y., Street Railway Co., was lately restricted by the board of councilmen to four miles an hour in the city and six miles in the suburbs. Since the reduction of speed was made, there have been many complaints, and the Real Estate Exchange has now unanimously adopted resolutions asking that a faster schedule be permitted. It pays the company a compliment in the preamble to its resolutions, saying that: "The Buffalo Street Railway Co. have with commendable enterprise and at great expense equipped many miles of their system in Buffalo with the trolley," which "has worked to great advantage in bringing the outlying districts of the city in close connection with the business centre."

ANOTHER ELECTRIC STREET CAR FENDER.

A successful test of an electric street car fender was recently made, it is reported, on the East Middlesex Street Railroad, Woburn, Mass. The fender is made of sheet iron and is attached directly to the framework of the truck. The lower plates come within about one inch of the rails, and are attached to springs of such stiffness that a fixed obstruction will pass under them while a movable object will be thrown aside. The fender will also serve as a snow plough.

MISCELLANEOUS.

ELECTRICAL TRANSMISSION OF POWER FOR COTTON MILLS.[1]

After a brief synopsis of the evolution of the electric motor, the various uses to which it is applicable and its advantages in cases where variable and intermittent service is required, the author confined himself to the consideration of electric work in cotton milling. The first motor used to operate an elevator in a cotton mill storehouse was installed in 1882 and is still in successful operation. The Salmon Falls Manufacturing Co. has 2,100 feet of track in the mill yard operated by the trolley system, the car running at an average speed of 600 feet per minute, moving all the cotton, supplies, cloth and coal handled on the premises, and taking the place of a team and three or four men. For inside service, the double overhead construction is necessary, as the occasional sparking at the rails, in the case of the single trolley system, is apt to ignite combustible material on the floors. The overhead wires should be thoroughly protected by guard wires, wherever a possibility of contact with other wires exists.

Electric cranes have great advantages in mills where constant service is required. The absence of heat, economy of space and ease of regulation possessed by motors fit them especially, also, for calico printing work.

Electrical distribution of power as a substitute for belt transmission has not yet been tried in cotton mills, but is, in the opinion of the author mechanically feasible. There is, of course, no doubt of its practicability in machine shops, but the amount of power required in cotton mills is very great, and the subdivision should be less than one unit to a room, so that when motors and generators, including wire and foundations, cost nearly or quite $100 per h. p., there seems to be some doubt as to the economy of the system.

At the Cumberland Mills, in Maine, 260 h. p. is transmitted over a mile by the Mather electric system, and motors are used to drive paper machinery, giving from poorly governed water wheels a sufficiently steady motion for calenders, but the compensation by the compound wound generators is not sufficient to remove the effect of all the variations of speed in the water wheels from appearing in the motors, and these motors cannot run Fourdrinier paper machines, although motors in these mills, deriving their power originally from a steam engine, perform satisfactory work in driving paper machines. At these same mills, an installation of motors is under way for the transmission of 1,200 to 2,000 h. p. for a distance of seven miles. As water wheels give sufficiently uniform speed for looms, and as motors do give a more uniform speed, there is but little question as to their mechanical suitability for such work.

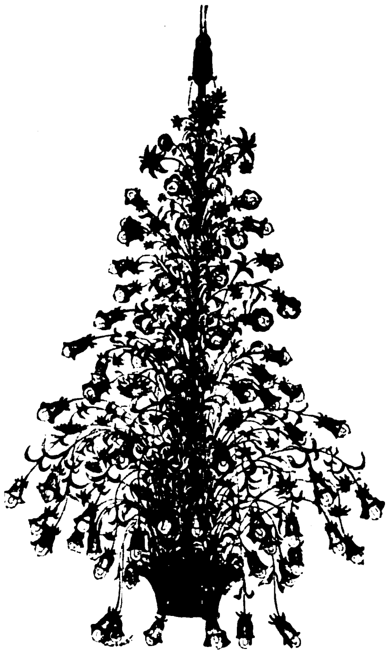
The Nonotuck Silk Company utilizes a waterfall of about 30 feet to run generators, whence power is transmitted to their mills at Leeds and Haydenville, the distance being ⅓ mile in one case and 1¾ in the other. There are two water wheels in use, one of 90 h. p., driving dynamos which furnish 950 incandescent lamps on an alternating system at the mills. The other 130 h. p. water wheel drives one Thomson-Houston generator of 85 h. p. and another of 30 h. p., the pressure of the current being the same as that used on trolley street cars. At the mills ⅓ of a mile distant is one motor of 45 h. p., two of 20 h. p., and one of 10 h. p., all supplied by electricity from the 85 h. p. generator. The 45 h. p. motor belts upon the main shaft, which is driven by two water wheels having a capacity of 100 h. p. under a 12½ foot fall. The water wheels are run at full gate without any regulator, but the motor serves as a regulator running at uniform speed and furnishing the remainder of the power, which has a variable range of 25 h. p. When the water falls too low for the water wheels and motor to run the mill, a steam engine is belted to the main shaft, the motor and water wheels furnishing their full capacity, and under these conditions the engine regulates the speed of the whole. Arrangements are being made to increase this plant.

The author then made some general statements in regard to long-distance electrical transmission of power, and referred to the natural advantages possessed by New England, where water power is being extensively utilized for this purpose. The present daily manufacture of incandescent lamps in this country is, he said, three times as great as the whole number in use here ten years ago, and there is no reason to doubt that the next decade will witness a comparable increase in the application of electricity to the transmission of power.

LETTERS TO THE EDITOR.

THE FIRST FIXTURE CALLED "ELECTROLIER."

In view of the forthcoming exhibition at Chicago, may we ask your permission to state that the celebrated electrolier originally manufactured by us for Mr. Edison's well-known exhibit at the Crystal Palace, 1882, has recently again come into our hands for sale?



The First Verity Electrolier.

It may be interesting to your readers to know that this is the *first* fixture to which the word "Electrolier" was applied, and it is in this and other respects a noteworthy curiosity, as it is one of the largest pieces of hand wrought floral work that has ever been manufactured. It stands about 16 feet high and is 10 feet broad, has 99 lights in three circuits, and originally cost over £350. It is now to be sold for £75; the metal alone in it is of considerable value.

Perhaps some of the prominent companies who propose making brilliant shows at Chicago, might feel disposed to utilize it "as the first electrolier that ever was constructed."

Verity & Sons.

London, Oct. 21, 1892.

[We are under the impression that the first "Electrolier" in the world is in the possession of Luther Stieringer, Esq , of this city, to whom it was given by F. R. Upton, Esq. It was put up at Menlo Park in 1880, and was fully described and illustrated in The Electrical Engineer, Aug. 12, 1891.—Eds., E. E.]

---

[1] Abstract of a paper read by C. J. H. Woodbury before the New England Cotton Manufacturers' Association, Boston, Oct. 26, 1892.

MR. BALCH AND HIS UNIPOLAR CRITICS.

MY article on "Twisting Magnetism," in your issue of September 14, has attracted considerable comment, and I trust that a discussion has been opened that is not without profit to your readers.

My first critic in your issue of September 21 quotes S. P. Thompson as saying that the moving conductor should cut the magnetic lines so as to alter the number that passed through the circuit. This statement, apart from the context, is certainly in error, for, if it were true, no unipolar machine would yield a current; but unipolar machines do work, and for equal lengths of conductor across the lines of force they do generate as much E. M. F. as other machines. Professor Thompson's error is one which has been committed so frequently by writers before him, that it is not surprising that he also should have made it.

My second critic in your issue of October 5 assumes that my magnets were solid instead of tubular. This mistake, however, does not alter what he has to say, which is, that my two operative unipolar machines will work if connected up in series. Mr. Tesla's invention of corrugated pole-pieces, as suggested by another correspondent, is not the solution at which I was aiming, for he produces an alternating and not a continuous current.

Mr. Hyer's reply, among those you have published, alone appears to show a careful reading of my article, and I take pleasure in thanking him for his pains in answering several of the criticisms which have appeared.

The explanation that will show at the same time why some of my experiments were successful and others were not, will have to recognize the fact that magnetic lines form permanent closed loops, and this is a fact that is not deducible from mathematical laws. A comparison of electrostatic and magnetic phenomena shows that Coulomb's and Ohm's laws are equally true of each. The attraction between electrostatic bodies, as well as between magnets, is inversely as the square of the distance, and the effects of electro or magneto-motive force are with each equally in keeping with Ohm's law. When two magnets are brought near each other so that lines of force lie between their adjoining poles, other lines of force will connect their separated poles, thus closing the magnetic circuit; but, if we approach two electrostatic bodies so as to set up an entirely analogous phenomenon between their adjoining surfaces or poles, there need be no corresponding phenomena connecting their separated surfaces or poles. In other words, these two phenomena, identical in their mathematics, differ in the fact that magnetic attraction can exist only in permanently closed loops, while electrostatic attraction does not require to be closed. The departure of the analogy here has not been explained.

S. W. BALCH.

NEW YORK, October 28, 1892.

APPARENT MAGNETIC RESISTANCE.

I HAVE read with some interest Mr. Steinmetz's article in THE ELECTRICAL ENGINEER on "Apparent Magnetic Resistance," because the ratio which he there defines and describes is one which I have often used without giving it any other name than the mathematical one, $\frac{d M}{d F}$. But I would like to add one qualification to his use of it, which he appears to have overlooked in the example he gives of its application to alternators.

Those of your readers who are familiar with Ewing's researches in magnetism will remember the very interesting and peculiar "loops" which he traced out at different points on his hysteresis curves by reversing the order of change in the magnetizing force at some point of the ascending or descending curve, and, after going back on his tracks a short distance, again reversing and going on with the main curve.

A glance at these loops shows that they only coincide with the main curve at two points, where they begin and where they end. The apparent magnetic resistance at any point then will depend on whether that point is on the ascending or descending leg of the curve and whether the added ampere turns are positive or negative. Thus, in the example given by Mr. Steinmetz in the second paragraph of the second column of page 241, since the curve is evidently an ascending one starting from zero, the value 13.08 would apparently be attained if the superinduced magneto-motive force is positive. If, however, it is negative, the induction, instead of coming down the way it went up, would start off on one of Ewing's loops, and the value to which it would be reduced would be greater than the 12.82 which Mr. Steinmetz gives, and if the magneto-motive force is alternated between these values, the induction would keep on following around this loop and would not simply go up and down on the curve of induction given.

This fact is of great importance in the effect mentioned by Mr. Steinmetz as occurring in the field of an alternator, on account of the varying magneto-motive force of the armature, since it makes the change in the induction through the field much less than it would be if Mr. Steinmetz's assumption were strictly true. As an additional proof of the truth of this assertion it may be said that if the magnetism went up and down on the curve of induction given by Mr. Steinmetz, there would be no hysteresis in the field cores due to change of magnetism, and that there is hysteresis, as well as eddy currents, in the field cores under these circumstances, I have learned only too well by sad experience.

Whether this peculiarity is apparent in compound-wound dynamos or in other direct current machines I do not know. I have never heard of any one's having discovered it, and I have had neither the time nor the opportunity to investigate it experimentally myself, but I should say that it was at least an open question, since the changes are so slow that the mechanical vibration would furnish another factor to the problem and one whose effect appears to be little known. I have sometimes thought, however, that the difficulty experienced in running compound-wound dynamos and series-wound street car motors in parallel might have some light thrown on it by taking this peculiarity into consideration.

THORBURN REID.

SETTLING A POLE LINE DISPUTE AT PEORIA, ILL.

THERE has been considerable friction between the local Telephone Co. and the commissioner of public works.

Some time since, the city council presented the Telephone Co. with a new franchise for which they had long been asking One of the conditions of the ordinance was that the Telephone Co. should present a map of the city on which were to be shown the routes of the wires. This was not done till the time they commenced work on the new lines.

The commissioner of public works, under whose superintendence the work was to be done, found that they were erecting their poles on the same side of the street as the wires of Jenney Electric Light Co. are. He ordered work stoped, but they did not stop, so the whole gang of linemen was arrested but later discharged upon condition not to work on that street till matters were fixed.

The commissioner of public works, Supt. Matlock of the Telephone Co., Supt. Findley of the Central R. R. Co., the mayor and Manager Reyburn of the Telephone Co. held a meeting, the result of which was that the Telephone Co. is to pay the cost of removing the electric light poles and wires to the other side of the street. The Telephone Co. and the Central Railroad Co. and the Central Electric Light Co. are going to use the same line of poles on certain streets, the Telephone Co. to remove the other companies' poles.

This is something which was badly needed, as there are three different sets of poles on the street now.

NO TELEGRAPH COMBINATION.

DR. NORVIN GREEN, president of the Western Union Telegraph Company, says the reports concerning a proposed union between the Western Union and Postal Telegraph had not the slightest elements of truth in them. Mr. Mackay has also denied the reports.

PERSONAL.

MR. F. R. COLVIN, an old Rochesterian, who has made both fame and fortune as the treasurer and business manager of THE ELECTRICAL ENGINEER, of New York, has just paid a flying visit to this city, with the special object of making a thorough personal inspection of the Denio auxiliary fire-alarm system, owned and installed by the Standard Electric Signal Company, which was clearly illustrated and described in a recent number of THE ELECTRICAL ENGINEER. Mr. Colvin has expressed himself as much gratified with the workings of the system, and does not hesitate to predict its speedy adoption, far and wide.—*Rochester, N. Y., Democrat and Chronicle.*

OBITUARY.

M. F. HATCH.

MOSES F. HATCH, of New Bedford, Mass., general manager of the Southern Massachusetts Telephone Company, dropped dead in the Park Square Station of the Old Colony Railroad in Boston, last week.

E. M. HOLBROOK.

MR. E. M. HOLBROOK, C. E., who was injured by the bursting of a fly wheel in the Brush Eiectric Light Works, at Niagara Falls, N. Y., October 16, has died from the effects of his injuries.

LITERATURE.

Handbook of Tables for Electrical Engineers. The John A. Roebling's Sons Co. Trenton, N. J., 1892. Pages, 119. 4½ x 7 inches. Price, $1.50.

WITH the great increase in the field of electrical industries in the past few years, there is a demand for special information which is not to be found in the older handbooks. This handbook is designed to give to the electrical engineer, in the form of tables, information which he could hardly obtain from any other source, or which would require long and tedious calculation. The book contains about 100 tables; these are divided into general tables, general tables of the line, calculations of the line, the overhead line, and the underground line.

Under the head of General Tables, only one can be noticed. It includes the metric system and all the English measures for length, area and volume. It gives at once the multiplier and its logarithm for changing from one unit to any other. In the table of lengths there is given the multiplier for changing inches into feet, yards, metres, chains, kilometres, miles and knots, and the same information is given for each unit of length. In a second table on the same page the logarithms of the multipliers are given.

Under "General Tables of the Line" there is a table giving the resistance of one mil foot of copper wire at various temperatures, calculated from Matthiessen's figures as given in the report of the Standard Wiring Table Committee of the American Institute of Electrical Engineers, September 16, 1890. This table will be appreciated by those who have to determine the percentage conductivity of copper wire. Following this are two tables, one giving the diameter and area in both square and circular mils, the other giving the resistance of wires per 1,000 feet in legal ohms and B. A. units at temperatures of 55° and 70°, according to all the wire gauges in use.

Under calculations of the "line", there are tables for wiring. From ½ to 9½ volts loss, inclusive, the resistance of the circuit is worked out for 100 amperes. From 10 volts loss to 20, the resistance is worked out for 200 amperes. To be used in connection with this table, is a table giving the resistance of copper wires from No. 0000 to No. 20 B. & S. The lengths for which resistance is given vary from 2,000 feet for the No. 0000 to 200 feet for the No. 20.

Following this are tables giving the formation of copper strands, the safe carrying capacity of wires, and complete tables of strains, lengths and deflections in the wire of spans. These tables were calculated so as to apply to the lengths of spans used in telegraph and electric railroad work. On page 115 there is a table giving the weight of wire from No. 12 B. & S. to 500,000 c.m. per 1,000 feet and per mile, bare, double braid and triple braid insulation. The last tables of the book are devoted to size and weights of all kinds of lead-encased cables, telegraph, telephone and electric light.

The book also contains a handy wiring chart, which, in connection with the tables mentioned, will greatly aid the laying out of electric light and power circuits.

Telegraphic Connections: Embracing Recent Methods in Quadruplex Telegraphy. By Charles Thom and Willis H. Jones. New York: *D. Van Nostrand Company.* 1892. Long 8°; pp. 59; 20 plates in colors. Price, $1.50.

WITHIN three or four years after the establishment of the first commercial telegraph line in the United States, the rapid growth and extension of the new system of intercommunication rendered necessary the invention of appliances for coupling different circuits together at junction points, in order to facilitate the interchange of business, and thus switches and repeaters first came into being. A quarter of a century later, the introduction of duplex, followed after a brief interval by the quadruplex method of working, brought many additional complexities and refinements into the organization of terminal stations. Then came the era of special and leased wires, and finally the whole terminal system had to be remodeled and reconstructed in order to adapt it to the changed conditions brought about by the substitution of dynamo-electric machines for the time-honored voltaic battery in the larger telegraphic centres of the country.

It has resulted from these conditions, that while the apparatus of the great majority of telegraphic stations has undergone but little change in form, and none at all in principle, for the last quarter of a century, a great number of special forms of apparatus and methods of working have been evolved by the incessant increase in the volume of service in the larger stations, the knowledge and understanding of which is practically limited to a comparatively small number of experts of long experience and of self-acquired skill.

While the work of Messrs. Thom and Jones is not the first attempt to produce a treatise dealing with the practical aspects of the service in the larger telegraphic stations of the present day, it is the only one of which we have any knowledge, which has been carried out in a way calculated to commend itself to the approval of the particular class of telegraphic employees for whose benefit it has apparently been prepared. It would be easy to criticise the work as a literary performance, but it would be most ungracious to do so, for it cannot be denied that the authors at least are familiar with their subject, and that they have sought to the best of their ability to impart their knowledge to others. Moreover there is no reason whatever to suppose that the average telegraphic operator will experience any serious difficulty in understanding the explanations.

The work, as a whole, has several very conspicuous merits. In the first place, it is neither too large nor too costly. It covers but a limited field it is true, but it is one that is only partially embraced in the scope of any prior work, and it must be admitted that it covers it thoroughly. The book is convenient in size and form, so that it may lie in a drawer of the instrument table, always at hand for reference when needed, without being in the way when not needed. As to the chief feature of the work, the illustrative diagrams of apparatus and connections, it would be difficult to speak in too high terms of praise. They are not only admirably designed, but are engraved in the finest manner, and printed, whenever necessary, in three colors, so that the most intricate arrangement of circuit-connections may be comprehended at a glance. They are beyond comparison superior to anything of the kind of which we have any knowledge. With such diagrams as these, labored and minute descriptions are tiresome and superfluous, and have been for the most part wisely omitted.

Many new devices are described and figured, which have only come into use during the present year, as a result of the complete reorganization and reconstruction of the New York station of the Western Union Telegraph Company, rendered necessary by the destructive fire of two years ago.

It goes almost without saying, that every telegraphic operator who cherishes an ambition to rise above the endless and toilsome grind of the key and sounder, will find ready to his hand in this book, a store of knowledge not easily attainable elsewhere, which cannot but prove of the utmost service to him in his efforts to render himself worthy of promotion. As a convenient work of reference, it possesses moreover, even to the expert, a distinct and positive value.

The publishers have done their work well. The engraving, printing, paper and binding are all of the best quality, and literally leave nothing in these respects to be desired. It is but fair to say that the plates are as nearly as possible fac-similes of drawings executed by one of the authors, and they certainly are of a quality and style which reflect the highest credit upon his taste and skill.

Electric Traction on Railways and Tramways. By Anthony Reckenzaun, C. E. London: *Biggs & Co.* New York: *D. Van Nostrand Co.* Cloth, 422 pages and index. Price, $4.00

THOSE of us who had the pleasure of making the acquaintance of Mr. Anthony Reckenzaun in this country a few years ago, when he came here to take a hand in the development of storage traction, will be prepared for something worth reading in this book, and they will not be disappointed. On the contrary they will be confirmed in the belief, that had he remained here, not only would storage traction have been much further advanced, but he would not have been reduced to the necessity of recording so much of other men's work in this, his chosen field of electrical application.

It is needless to say that Mr. Reckenzaun could only write a helpful and instructive book, no matter what his disadvantages in the way of observation of actual work, and the treatise before us can be heartily recommended as a study of something more than familiar facts and surface indications. There are only half a dozen chapters in the book, but each is well planned and well weighed. Perhaps that on storage work is the most valuable to the American electrical engineer, as it embodies results of personal practice and experience and the suggestions of a shrewd observer. It is moreover, of a cheerful and sanguine cast. We object, all the same, to the placing of Figs. 48 and 49, referred to in this chapter, just 100 pages ahead of the reference. This is like the annoying habit of American magazines, which put all their beautiful cuts in a bunch on the fine coated paper, and then let the text they relate to straggle along a score of pages later, on "ornery" 10 per cent. rag.

The main point is, however, that Mr. Reckenzaun adheres to his liking for storage traction; and we can see no reason why, in the long run, he will not be found right and justified. So, too, we note that his convictions as to the suitability of the worm gear remain unchanged. He argued for worm gear when among us in America and he is not slow to point out its merits to-day.

Of minor defects the book exhibits but few. It complains that total efficiency tests of electric railway systems are few and not often accurate. Our opinion, on the contrary, is that we are getting too many of these tests and that they do but confirm each other, evincing a fair average of accuracy. If one could only persuade our graduating electricians to do aught else than make an efficiency test of an electric road for their theses, life would be far more worth living. We note, too, that Mr. Frank J. Sprague is referred to on page 121 and elsewhere, as though he were still pegging away at street car motor regulation. As a matter of fact, Mr. Sprague long since tackled heavier problems than this in electric locomotion, and we doubt very much whether he has deigned to dally with the old Sprague car motors since their change of financial control relieved him of worry as to the electrical. So, too, we observe the Bentley & Knight conduit system spoken of on pages 165 and 166, in respectful terms of the present tense. That system, excellent as it was in many respects, had its day and ceased to be several years ago, after absorption in the usual Nirvana fashion by the Thomson-Houston Company; but perhaps we shall see it again some day in a further stage of metamorphosis.

The book is got up in good shape, and is well printed, though some of the engravings have that tired feeling and look which would indicate frequent service. There should be a law, we think, to exempt cuts from duty after a given term of work. The printing press is a Sullivan that will "knock the stuffing" out of even the hardiest electro. But in the main, the illustrations are clear and useful, and Mr. Reckenzaun is as moderate in employing them as he is in resorting to adjectives when describing the machines and plants they relate to. It is sincerely to be hoped that Mr. Reckenzaun will come over and see us next year. This country will then furnish him with all the new data, fine cuts, and superlative adjectives that he can possibly squeeze into his second edition. Meantime, we hail his admirable book as the only European production on this subject worth reading on both sides of the Atlantic.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED OCTOBER 25, 1892.

Accumulators :—

Secondary Battery, W. Main, Brooklyn, N. Y., 485,018. Filed Feb. 15, 1892.

Comprises a number of improvements upon the former Main batteries, one of which is a vertical copper plate supporting electro-deposited zinc.

Finishing Grids for Secondary Batteries, A. F. Madden, Newark, N. J., 485,128. Filed June 17, 1891.

Conductors, Conduits and Insulators :—

Wire Coupling, W. E. Banta, Springfield, Ohio, 484,842. Filed, Sept. 12, 1890.

The coupling is composed of coiled wires joined together and adapted to bite into the line wires under the coupling strain.

Closed Conduit for Electric Railways. B. F. Sutton, Brooklyn, N. Y., 484,924. Filed July 7, 1891.

Employs a tube of insulated material free to collapse and expand, and enclosing a conductor; a number of separate conducting services on the interior of the tube, and a conducting surface on the exterior of the tube, communicating electrically with the separate conducting surfaces when the tube is compressed.

Insulator for Electric Railway Conductors, C. T. Lee, Boston, Mass., 485,105. Filed March 17, 1892.

An insulated wire handle, in which the insulated part and the case containing them may be rotated within the collar.

Insulator, C. T. Lee, Boston, Mass,, 485,106. Filed March 17, 1892.

Consists of a block composed of mica sheets secured together and a spindle passing partly through the block.

Dynamos and Motors :—

Magneto-Electric Generator, S. Evershed, London, England, 484,785. Filed Jan. 8, 1892.

A dynamo-electric generator which, when used with an ohmmeter, will give a constant electromotive force.

Regulation of Alternating Current Generators, G. Pfannkuche, Cleveland, Ohio, 485,054. Filed Nov. 30, 1887.

Relates to system of regulating of alternating current generators whereby the latter become adapted for use in general systems of distribution in which the number of translating devices is variable.

Galvanic and Thermo-Electric Batteries:—

Standard Cell for Electric Batteries, H. S. Carhart, Ann Arbor, Mich., 485,089. Filed July 11, 1892.

Employs a mercury salt connected with one terminal of the cell, a zinc element connecting with the other terminal, an electrolytic fluid in contact with the zinc and mercury salt, and a porous partition between the latter.

Lamps and Appurtenances :—

Incandescent Lamp, F. S. Smith, Pittsburgh, Pa., 484,825. Filed Feb. 29, 1862.

Invention consists in making the enclosing chamber in two parts, the larger part being of glass and the remainder of a soluble material which will make an air-tight joint with the glass part and may be separated therefrom by immersion in a proper solvent. (See THE ELECTRICAL ENGINEER Nov. 2, 1892.)

Electric Search Lights, L. Hills, New York, N. Y., 484,964. Filed Sept. 24, 1891.

Relates to methods of mounting and moving the frame of the projector.

Miscellaneous :

System for Adjusting to Temperature Watch Balances and Hair Springs, G. E. Hunter, Elgin, Ill., 484,796. Filed Jan. 26, 1892.

Employs an electric device for registering a number of vibrations of a standard balance or spring for purposes of comparison.

Mechanisms for Timing and Adjusting Watch Balances and Hair Springs, G. E. Hunter, Elgin, Ill., 484,797. Filed Jan. 26, 1892.

Similar to 484,796.

Process of Separating Gold and Other Metals from Their Ores, G. T. Atkins, London, England, 484,869. Filed April 28, 1891.

An electrolytic method of separation.

Process of Separating Iron from Ore, M. F. Eaton, Chicago, Ill., 484,877. Filed April 6, 1889.

A system of magnetic separation.

Electric Converter, L. Gutmann, Fort Wayne, Ind., 484,959. Filed Feb. 5, 1889.

Claim 1 follows:

The combination with energizing coils of a core composed of superposed insulating plates and a conductor connecting electrically plates separated from one another by others.

Trolley-Pole Catcher, M. M. Wood, Chicago, Ill., 484,986. Filed June 4, 1891.

Employs a motor to which is attached the rope leading to the trolley pole and which is actuated by the tension of said rope caused by the trolley leaving the wire.

Electrolytic Process and Apparatus, H. Blackman, New York, N. Y., 484,990. Filed Jan. 15. 1892.

Claim 1 follows:

The improved electrolytic process consisting in subjecting an electrolyte to centrifugal action during the electrolysis, whereby the resulting products of different specified gravities are separated.

Electric Soldering, E. E. Ries, Baltimore, Md., 485,017. Filed July 17, 1891.

Railways and Appliances :—

Electric Railway System, J. H. Pendleton, Brooklyn, N. Y., 484,919. Filed Aug. 1, 1891.

Combines in its structure a supply conductor, a sectional working conductor, interposed energizing sections, a primary branch wire for each section of the working conductor, leading from the supply conductor and including an electromagnet, and a second branch wire for each energizing section leading from the main branch wire to the energizing section; the one coil of the electromagnet being included in both branch sections.

Switches and Cut-Outs :—

Thermal Circuit Changer and Protective Appliance, H. A. Rodes, Denver, Col., 484,822. Filed March 11, 1892.

Employs a substance having a high coefficient of expansion enclosed in a vessel having an elastic wall, for the purpose of making and breaking contacts under the influence of greater or less degrees of heat.

Automatic Cut-Out, C. E. Sanford, Brooklyn, N. Y., 484,865. Filed May 17, 1890.

Consists of a series of electromagnets whose resistances diminish in a prescribed ratio, and which are each provided with an armature acting as a circuit cut-out for a branch circuit.

Ceiling Block, J. J. Green, Boonton, N. J., 484,911. Filed May 17, 1892.

Employs an annular packing between the block and the cover for the purpose of excluding moisture.

Electrical Switch, G. Binswanger, London, Eng., 485,028. Filed May 6, 1892.

Employs a contact bar, a rocking handle, a cam thereon bearing upon the bar, a spring to lift the bar, and a link loosely connecting the bar and handle.

Telephones and Apparatus :—

Telephonic Transmitter, A. T. Collier, St. Albans, Eng., 484,778. Filed Dec. 8, 1891.

Employs a diaphragm secured upon an annular frame suspended upon a rod depending from a support pivoted to the frame of the transmitter, and means for adjusting the diaphragm and its electro with respect to the back electro.

Test Circuit for Multiple Switchboard Systems, C. E. Scribner, Chicago, Ill., 484,867. Filed Mar. 1, 1890.

Employs an electromagnet introduced between the last switch of the multiple switchboard system and the test rings of the switches; the armature controlling contact points which are included in a branch circuit to ground.

Telephone Support, G. V. Benjamin, Ithaca, N. Y., 485,027. Filed Mar. 19, 1892.

LEGAL NOTES.

EDISON ELECTRIC LIGHT COMPANY AND EDISON GENERAL ELECTRIC CO. vs. SAWYER-MAN ELECTRIC CO.

THE hearing in the Edison suit against the Sawyer-Man Co., on the new motion for preliminary injunction, appointed for Friday, November 4, and noted in our columns last week, was on that day postponed for one week—till Friday, November 11.

CHANGES IN WESTERN UNION RATES.

SEVERAL changes in the rates for telegraphic messages made by the Western Union Company, which went into effect on Oct. 1, have escaped notice, except among those who have considerable telegraphing to do, and to whom the slightest reduction in rates means great saving of expense.

The most important change which has been made is in the manner of charging for numbers. Formerly, in a number, every figure was counted as one word, but under the new system figures, letters, commas, points, and bars of division, or any combination thereof, (as in cipher messages), are counted three figures, letters, or signs to the word, and any group thereof of less than three figures, letters, or signs is also counted as one word. To prevent liability to error, numbers and amounts should be written in words, and this makes no difference in the charge.

Other changes which have been made are in reference to the body of a message where dictionary words, initial letters, surnames of persons, names of cities, towns, villages, States or Territories, or names of the Canadian Provinces are counted and charged for as only one word, while in the names of counties and countries all the words are counted.

Thus the names of cities and towns, as New York, St. Louis, White Plains, count only as one word each, while New York County is charged for as three words.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

The mint is the only place where money is made without advertising.

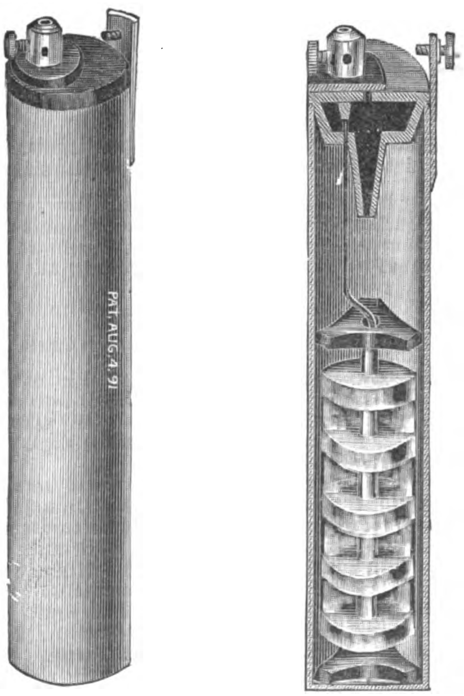
THE NEW "HARD" DRY BATTERY AND BELL.

There are many situations where a handy portable cell can be applied with advantage, not only in electrical testing work, but also in the more general electric bell and annunciator work, where heretofore the ordinary open circuit galvanic cell has been employed.

In seeking to devise a practical commercial cell of small size and of durable quality for these purposes, Mr. J. Randolph Hard has recently succeeded in developing a new type of the chloride of silver cell, which possesses a number of valuable features. Our engraving, Fig. 1, shows the cell complete, in full size, and its internal construction will be readily understood from an inspection of Fig. 2. Here it will be seen, that the silver wire passing down from the outer terminal has cast around it a number of discs of chloride of silver, between which an exciting paste is inserted, which acts as the electrolyte. This silver wire is maintained in a central position by a triangular washer above and below the chloride discs.

One of the greatest difficulties heretofore encountered with the chloride of silver cells is their bursting, owing to the pressure of the gas generated by the action of the cell. To avoid this, Mr. Hard has inserted at the top of the cell a funnel-shaped hard rubber stopper, having a small perforation at its centre. This perforation is covered by a soft-rubber flap placed under the terminal post, which acts as a valve. Normally the rubber flap seals the top of the funnel, closes the central orifice, and thus prevents the evaporation of the electrolyte. But it is evident that any gas generated when slightly exceeding normal pressure, readily escapes by the valve, which immediately closes the orifice again. The funnel shaped stopper also prevents the liquid, which is generated by the action of the cell, from slopping over when the cell is placed in an inverted position, as it may be placed occasionally. The liquid it will be evident flows around the funnel, and the nozzle prevents it from overflowing; the liquid generated being of such small volume as not to exceed the height of the funnel.

The action of the cell is very constant. It has been used with success in ringing door bells, operating burglar alarms, electro-medical apparatus, testing work, etc. Two such cells are able to ring a bell vigorously, and as they can be placed in a small case, the time and expense are greatly obviated, it being unnecessary to run the circuit to batteries kept in cellars or closets, as is now generally done.



Figs. 1 and 2.—New "Hard" Dry Battery.

The vibrating bell recently brought out by Mr. Hard, which is illustrated in Fig. 3, also embodies several novel features. In the first place the use of all pivots has been avoided by suspending the armature in front of the electromagnet upon a spring, its centre of vibration coinciding with the hole in the box through which the hammer rod passes. The brass spring to which the armature is attached also carries near its central portion, the contact which makes and breaks the current.

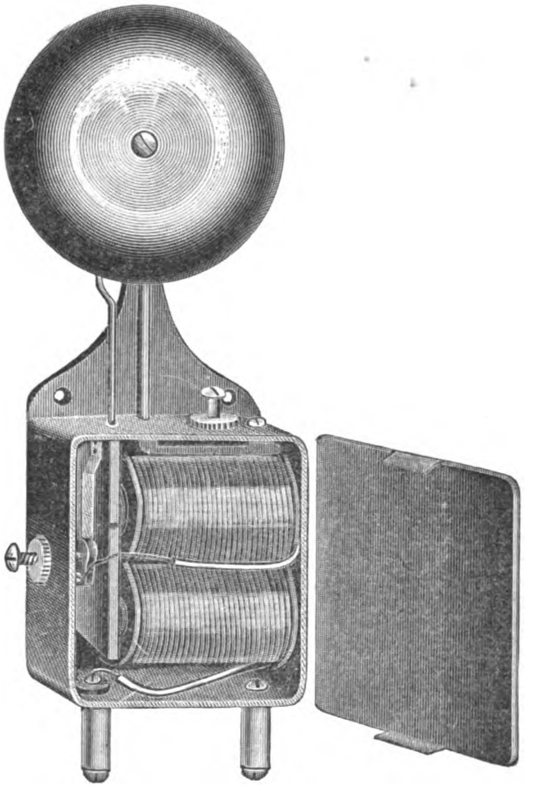


Fig. 3.—New "Hard" Vibrating Bell.

By the arrangement here adopted a very small amount of current is required to operate the bell, and there are no false vibrations produced. It will also be noted that the hammer strikes the inside of the bell instead of the outside as is usually the case. By this arrangement the danger of getting the bell out of adjustment when cleaning or dusting is entirely avoided.

As is stated above, the armature is so hung that the centre of vibration coincides with the hole through which the hammer arm passes. The result of this is that this hole requires to be only sufficiently large to allow the hammer arm to pass through comfortably, and still without interfering with the free vibration of the rod. This close fit between the hammer rod and the hole, makes the bell perfectly dust and insect proof. The front of the bell box is closed by a lid, which is held in position by tongues above and below, that lock the lid firmly in position.

These devices are now being regularly manufactured by Mr. J. Randolph Hard, 2 and 4 Howard street, New York.

THE DIXON POWER AND LIGHTING CO.

The new station of the Dixon Power and Lighting Company, of Dixon, Ill., is rapidly approaching completion. The building is six stories high, 80 x 50 feet, and has an addition for a boiler house, and the dynamo shaft is so arranged that the generators may be run all by steam, all by water power, or part of the number by each. The Thomson-Houston system will be used, and the steam plant will consist of two 125 h. p. Armington & Sims high speed engines, with a 400 h. p. Babcock & Wilcox boiler.

There will also be three 90 h. p. New American and one 90 h. p. Leffel water wheels, each provided with a Woodward governor. It is the intention of the company to make the plant a model one in every respect. The dynamo shaft is equipped with 10 Eclipse friction clutch pulleys. Rope drive transmission is used on the water wheel shaft and the countershafts, and belts on the dynamos.

The company is capitalized at $75,000, and will furnish light and power over circuits aggregating 28 miles in length. The officers are: F. A. Watson, president; George Steel, vice-president; G. C. Loveland, secretary and treasurer; E. P. Maxwell, superintendent, and P. E. Cowles, electrician.

IMPORTANT NEW MEASURING APPARATUS.

The study of applied electricity is now so universal that high schools as well as colleges devote considerable time to the subject. Apparatus adapted for research work is quite too costly for elementary instruction, and in consequence until recently many schools have not been able to treat this important branch as fully as was desirable. Instrument makers are appreciating the need for first-class elementary instruments, and in this issue we give a brief description of a few important pieces which are being placed on the market by Messrs. Queen & Co., of Philadelphia. The different pieces have been designed in their laboratory, and are constructed substantially, but without the same degree of finish which is placed on the finer apparatus that this firm makes.

Fig. 1 shows a D'Arsonval galvanometer intended to be placed against the wall of a laboratory. It has a graduated scale with pointer and also a mirror, so that readings may be taken directly or by means of a telescope or lamp and scale. This instrument is extremely dead beat, and is adapted for general work where quick measurements are desired.

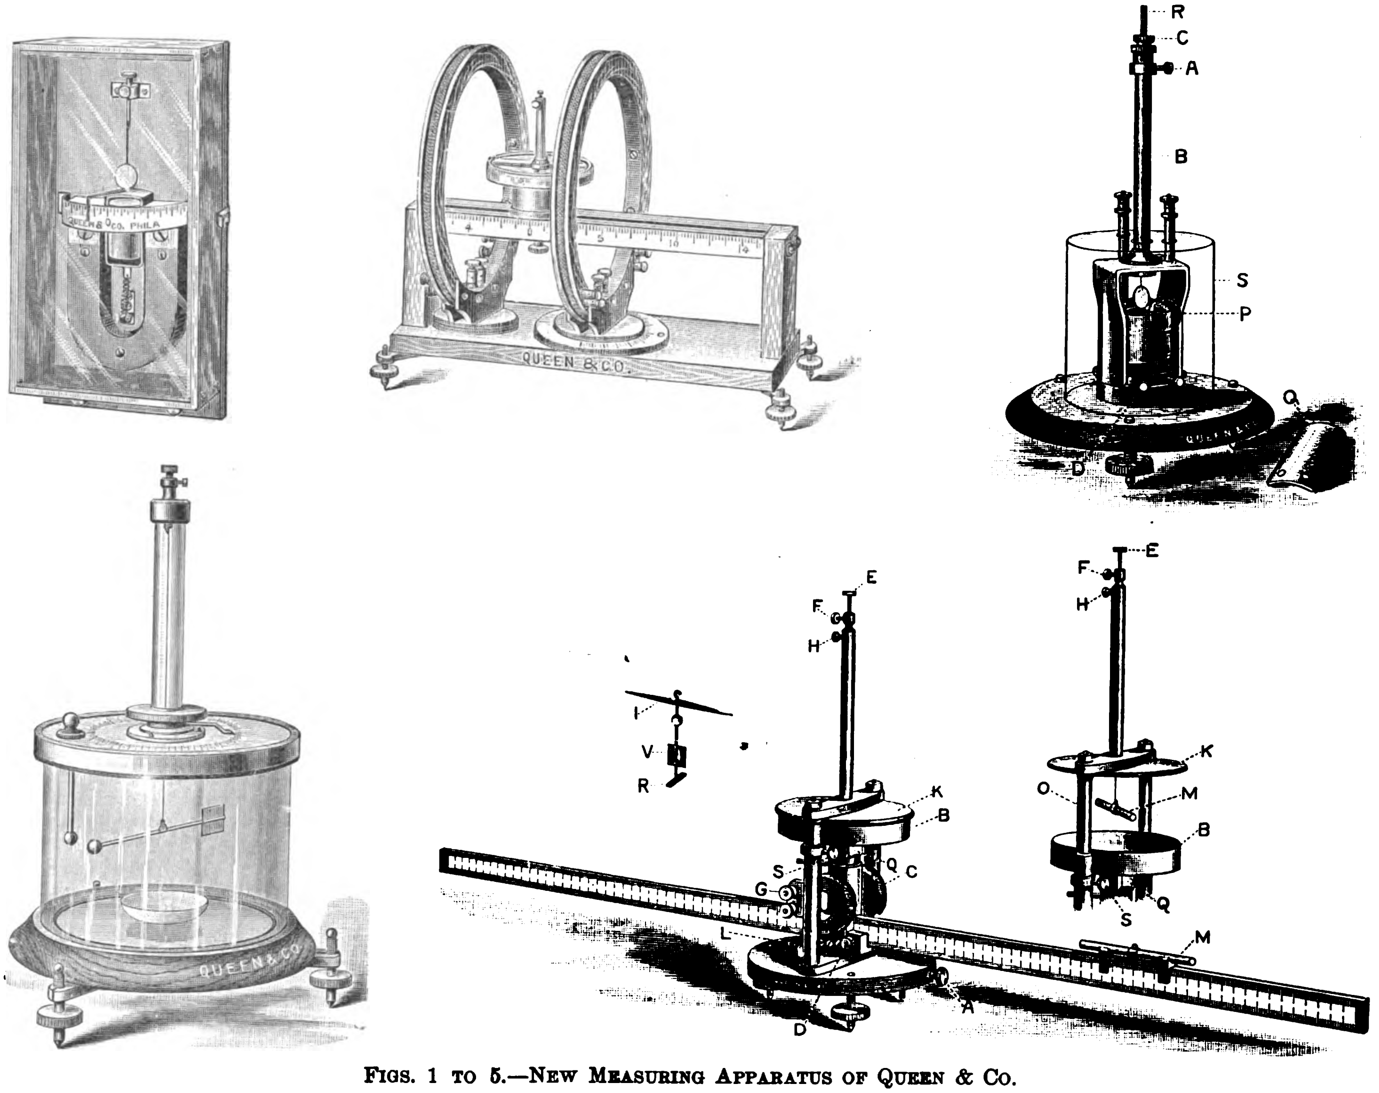
Fig. 2 represents a universal tangent galvanometer which is especially designed for determining current in absolute measure and for showing the effects of variation in the different quantities contained in the tangent galvanometer equation. It has two mahogany rings, built up of a number of pieces to prevent warping. One ring is wound so as to rotate freely on a vertical axis, with a pointer and scale graduated to degrees for use in sine measurements. The compass box slides along the horizontal graduated bar so that the needle may be placed in the plane of either coil, as a tangent galvanometer; midway between them as in a Helmholtz Gaugain galvanometer, or at any point upon the axis outside the places of both coils as in the Weidemann type. The instrument can thus be used for a great variety of purposes.

The quadrant electrometer, Fig. 3 is intended for use by the beginner, and is of simple construction while capable of a high degree of accuracy. The quadrants are fastened to a circular block of hard rubber, two of them being made of one piece of metal bent so as to have a level surface on top, to which the brass suspension tube and one binding post are attached. The aluminum needle, provided with mirror for reading deflections and vanes for damping the system, is suspended from an adjustable torsion head, thus connecting it with one pair of quadrants. In this way the Leyden jar arrangement, otherwise necessary for maintaining the needle at a high potential is avoided. A metal case encloses the apparatus, leaving room inside for a small dish of sulphuric acid and pumice stone for drying purposes.

Fig. 4 represents a coulomb electrometer which differs from other types in that the suspension tube is free to rotate, and at the bottom carries a pointer which moves over a scale graduated on top of the glass case. A mirror is placed in the bottom of the case to avoid parallax.

Fig. 5 represents a very convenient form of magnetometer which will prove invaluable for laboratory work. The illustration is very clear, so that it is not necessary to give details of construction. Observations may be taken either directly by aid of pointer deflections or by the telescope and scale method, a mirror being attached to the magnet system. Results almost as accurate can be obtained with this apparatus as with the well-known "Kew" pattern which is very much more expensive.

Messrs. Queen & Co. are issuing a special circular containing prices and full particulars in reference to these instruments.

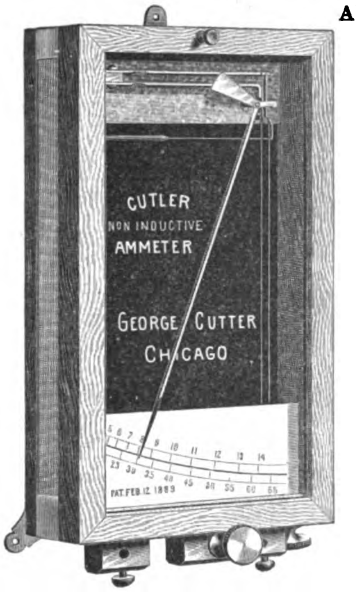


Figs. 1 to 5.—New Measuring Apparatus of Queen & Co.

ELECTRIC ENGINEERING AND SUPPLY COMPANY.

The above concern of Syracuse, N. Y., report themselves extremely and even "uncomfortably" busy. Their big World's Fair order is progressing nicely, but they are compelled to run night and day to meet the requirements thereof and to keep up stock for regular customers at the same time. They are putting in additional machinery, and expect to catch up with and supply the demands no matter what the increase in their future trade.

THE CUTLER NON-INDUCTIVE AMMETER.



Cutler Non-Inductive Ammeter.

ALL of the ammeters on the market with perhaps a single exception, depend on magnets for their action, so that their readings are largely influenced by the presence of iron masses near by, In a station where there has to be so much heavy machinery, this factor oftens spoils all dependence on the readings. And even if the instruments are placed at a distance from the dynamo and engine-room, two of them placed side by side will affect each other's readings. These are a few of the reasons why an ammeter having no magnets ought to be more reliable and better adapted to central station work than any magnetic instruments.

The non-inductive ammeters devised by Mr. H. H. Cutler depend on the difference in expansion of two fine wires, one of which is traversed by the current to be measured while the other compensated for changes in temperature of the room. The two wires are fixed at one end and are kept taught by flat springs carrying two knife-edges. A yoke resting on these bearings carries a light pointer, the leverage being such that quite a small expansion of the measuring wire will move the needle across the scale. The instrument is practically dead beat, and could be set on the pole-piece of a dynamo without affecting its readings.

The cut illustates an ammeter made with a double scale to read up to 65 amperes, the scale being much longer than in most instruments of this kind. This ammeter is equally accurate on direct or alternating circuits and steady use for the past six months has shown it to meet the needs of central station practice. It is built in sizes ranging up to 160 amperes, to meet the varied requirements of different stations, and the maker, George Cutter, of Chicago, is finding quite a demand for it.

SUBDIVISION OF POWER.

THE most persistent advocates of subdivided power, as engineers, have probably been Messrs. Westinghouse, Church, Kerr & Co., and many important plants have been designed by them on this basis. The results are beginning to speak for themselves and are of interest.

In the great Spreckels sugar refinery the subdivision of power involved over 60 high-speed engines distributed on every floor of the enormous building; most of them set without foundations. Non-compound engines were employed, from the fact that the various processes utilized all the exhaust steam which could be made. An order has just been placed with M. R. Muckle, Jr., & Co., of Philadelphia, for five more Westinghouse "Standard" engines, four of 100 h.p. and one of 75 h.p., making 68 engines now operating in this refinery.

The master mechanic keeps on hand a set of duplicate parts for each size of engine, and when a part is worn out, or an accident occurs, it is at once replaced; the old part being returned to the shop and overhauled at leisure.

A similar subdivided plant, involving 42 engines, was installed at the print works of the Dunnell Manufacturing Company, Pawtucket, R. I., and its chief engineer reports that the total repair bill for the first year of continuous operation was less than three dollars.

RECENT SALES OF ERIE BALL ENGINES.

THE BALL ENGINE Co., of Erie, Pa., report the following recent shipments:

General Electric Co., Atlanta, Ga., one 150 h. p. engine; Lake Shore Iron Works, Marquette, Mich., one 60 h. p. engine; Risdon Iron Works, San Francisco, Cal., one 25 h. p. engine; Badenoch Bros., Englewood, Ill., one 600 h. p. engine; Calvert Building and Construction Co., Baltimore, Md., one 80 h. p. engine; Calvert Building and Construction Co., Baltimore, Md., one 130 h. p. engine; Calvert Building and Construction Co., Baltimore, Md., one 35 h. p. engine; Excelsior Electric Co., Port Huron, Mich., one 400 h. p. engine; F. R. Dravo & Co., Pittsburgh, Pa., two 80 h. p. engines; F. R. Dravo & Co., Pittsburgh, Pa., one 100 h. p. engine; F. R. Dravo & Co., Pittsburgh, Pa., two 25 h. p. engines; Crook, Horner & Co., Baltimore, Md., two 80 h. p. engines; Crook, Horner & Co., Baltimore, Md., one 60 h. p. engine; J. H. Kuehling, Washington, D. C., one 60 h. p. engine; Risdon Iron Works, San Francisco, Cal., one 150 h. p. engine; General Electric Co., New York City, one 100 h. p. engine; General Electric Co., New York City, one 100 h. p. engine.

THE WESTINGHOUSE RAILWAY SYSTEM IN NEW ENGLAND.

MR. R. S. BROWN, the active and debonnaire agent of the Westinghouse Company in New England, reports a number of new orders for street railway apparatus. The Holyoke Street Railway Company has ordered four car equipments of two 20 h. p. motors to each car; the Hartford and Wethersfield Company one 250 h. p. generator and three car equipments of 60 h. p.; the Worcester Consolidated Company two car equipments of two 20 h. p. to each car; and last, but not least, 12 car equipments of two 20 h. p. motors to each car for the Springfield, Mass., Street Railway Company. Mr. Brown regards this last order as the best possible refutation that could be given of certain figures published recently with the object of showing that the Springfield Company did not think much of the efficiency of the Westinghouse apparatus.

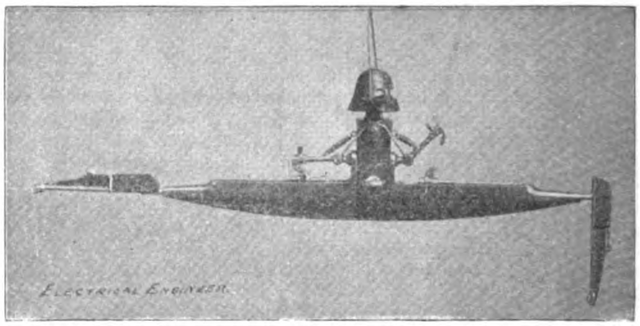
THE COMMERCIAL ELECTRIC COMPANY.

THE above company has been organized in Indianapolis to manufacture dynamos and motors under Mr. A. D. Adams' patents and they are about to place on the market a complete line of machines embodying novel features of construction. Mr. Jos. R. Evans is president; Mr. S. L. Hadley, secretary; Mr. W. A. Evans, treasurer, and Mr. A. D. Adams, manager of the new company. Their office and factory is situated at No. 113 South Tennessee street, and their machines will include power generators, lighting and plating dynamos and motors of all sizes. Mr. Adams has had considerable experience in the manufacture of electrical machinery and the new company ought to experience no trouble in securing a large and profitable business.

THE JOHNSTON DISCONNECTOR.

THE accompanying illustration shows the latest improvement in the Johnston safe automatic disconnector, with the original form of which our readers are already familiar.

This device, when applied to any wire bearing a dangerous current will, in the event of the rupture of the wire from any cause instantly break the circuit, and the wire will fall to the ground uncharged and can be handled with impunity. It offers special advantage and facility for repairs to any portion of the line without interference with the service of any section except that where repairs are to be made, and without in any manner affecting the machinery at the power house.



NEW JOHNSTON DISCONNECTOR.

In addition to the springs and clips, the new form of this device has a fuse wire as shown, which will blow in the improbable event of the springs' failure to act. As will be seen also, each end is hinged to the main portion and will fall by gravity the moment the wire breaks.

The device is manufactured by the Johnston Safe Automatic Electric Co., Richmond, Va., of which Mr. A. Langstaff Johnston is president and Mr. F. B. Jacobs is secretary and treasurer.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.

THE
Electrical Engineer.
VOL. XIV. NOVEMBER 16, 1892. No. 237.

THE TUDOR ACCUMULATOR IN CENTRAL STATIONS.

BY

Dr Paul Schoop

IT seems that a "well known" American engineer is in doubt as to the early introduction of accumulators in American central stations, judging from an editorial on "Storage Batteries in Central Stations" appearing in THE ELECTRICAL ENGINEER, of August 31. The statements there made are so entirely misleading that one would be at a loss, in my opinion, to go further in the wrong direction. I beg therefore to be allowed to clear up one mistake after another. The editorial stated, "Our informant tells us that he was struck with the smallness of the plants." I give below a list showing the sizes of half a dozen plants in Germany (see page 468).

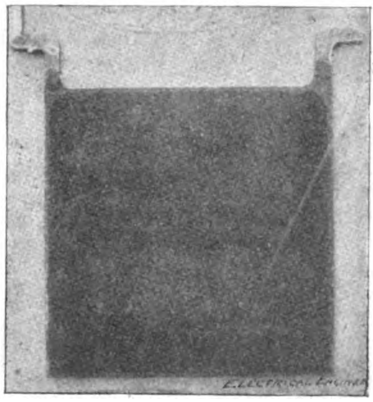


FIG. 1.—TUDOR ACCUMULATOR, POSITIVE PLATE.

To be struck by the smallness of a plant whose capacity is nearly 3,000 h. p. hours, and whose normal discharge is 625 h. p. (in case of emergency for short intervals even double that number, or 1,250 h. p.)—and this for the accumulator battery alone, is certainly worthy of note. "The load diagrams" says your informant, "are Alpine in the sharpness of their peaks and the sheer depth of their valleys," but he gives no reasons for, nor does he prove, this very doubtful assertion. Are the days in Europe constructed differently from those in America? Or do Americans work during the night and sleep in the day time? It might be well to compare the load diagrams of the stations mentioned in the above table with those of the Edison stations in New York and Chicago. The writer, however, does not believe that there should be such a difference between American and European load diagrams as a rule.

Your informant finds further an "undue proportion of the batteries to the generating plant in space occupied." Here again we have proof that your informant did not have complete data on the subject. As a rule the battery does not occupy more space than a dynamo plant, including the necessary steam engines and boilers. Only in such cases where gas engines are used would the proportion appear to be unduly great. I believe that the space required by a battery is, up to the present, one of the least obstacles to its introduction. But if fault must be found at all hazards it must be confessed that the much-sought-for battery in a cigar box would constitute actual progress.

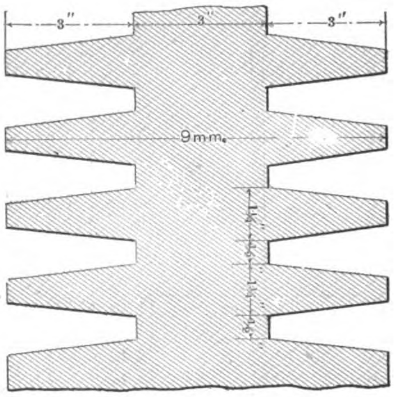

FIG. 2.—SECTION OF TUDOR POSITIVE PLATE.

I hardly agree with the remarks of THE ELECTRICAL ENGINEER, that "as for care bestowed upon the apparatus that is a lesson we still have to learn from the Europeans and the Japanese." Because an apparatus requires supervision, and a treatment different from that of a dynamo, the trained observer heaves it into the scrap heap—and makes an assignment (of his perfect inability to take care of electrical apparatus). If the amount of care required were such an important item as would appear from the remarks of your informant, it would make the central stations in Germany less profitable than they are. It seems more probable that the American engineer whom you quote

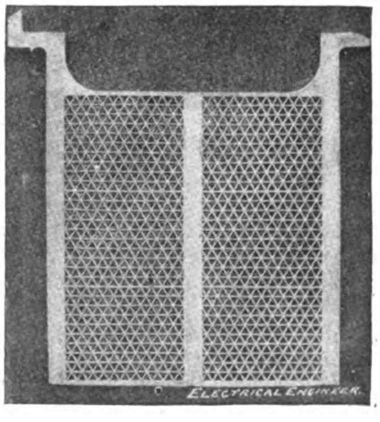

FIG. 3.—TUDOR NEGATIVE PLATE.

had formed his opinion before he went abroad, and has succeeded in sticking to it in spite of the impressive stations he saw. I admit that it is not unnatural that sore feelings should exist in some quarters on the subject of accumulators, considering the many unfortunate experiences with them, especially in America.

The Electrical Engineer has pointed out one of the main reasons why, in America, batteries have not made good records up to date. It is less a want of time than a want of devotion to this kind of apparatus on the part of the workmen that has caused a good deal of disappointment. Another reason is the method of employing the batteries. With their well-known energy American engineers have put themselves to the hardest task in order to make battery stations successful, and that they will finally succeed is not doubted by those who are following their work.

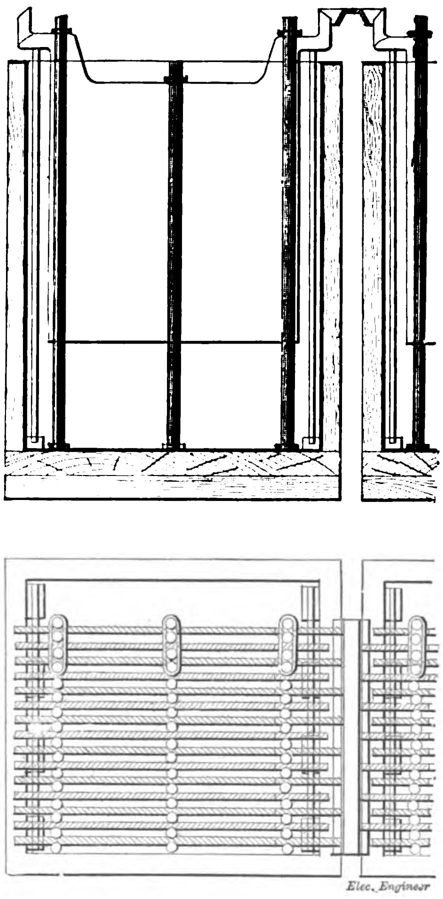

Fig. 5.—The Tudor Cell, Section and Plan.

"Gautherot" has made friends here, too, by his perfectly impartial and able article in The Electrical Engineer. Too much history has been repeated in America regarding storage batteries.

While struggling with this task, in Germany, and on the Continent in general, fruits have been gathered by those interested in storage battery work. It might be gratifying to those who are still in the battle to know that one factory at least, the Accumulator Works in Hagen, Germany, have in the last two years sold batteries amounting in value to $2,250,000, and have for the past three years paid 10 per cent. dividends. More than 2,000 batteries of various sizes have been sold during that time exclusively for lighting purposes. The success here accomplished may make it interesting to investigate closer the basis of this first financial success in this field.

The system adopted by the Works above mentioned is that of Henry Tudor, and is materially different from that of any other system in use to-day, not only in respect to construction of plates, but also in the method of operating, managing, and employing the batteries. The latter is not the least important point, and needs more elucidation.

The Tudor-plate.—As is well known, the positive plates are generally those whose short life has given such frequent trouble. The Planté plate with its electrolytically formed layer of active material has not yet been introduced in practice (as far as the writer is informed) and all the grids provided with active material according to Faure's process, have had but a short life in many cases. Mr. Tudor has, for the first time, adopted the golden mean; the positive plate shown in Fig. 1, is cast and represents a surface with small parallel grooves, while Fig. 2 gives its exact cross-section. A peculiar forming process first provides the cast plate with an active layer, and after this layer has been established, red lead is applied as a paste according to Faure's method. But this paste is not intended to provide for the capacity of the plate, except during its early life (between 6 and 10 months). It falls out of the grooves after that time and is just so calculated that the *Planté layer* which has been formed on the surface during that time *provides for the entire capacity* after the first year of use.

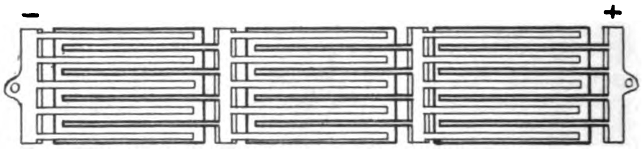

Fig. 4.—Method of Connecting Plates in Series.

The surface of the conductor or plate is larger than in other known plates, and owing to this circumstance, affords not only a considerable Planté layer, but also makes possible very large rates of charge and discharge. These plates are easily charged within 4 hours and discharged within 3½ hours; these are the *normal* rates which may be doubled for short intervals. This fact is both electrically and commercially valuable. The cost of the cells for discharge-current of 1,000 amp-hours is about 1,000 frs. ($200), while for especially heavy discharges it amounts to 500 frs. ($100). The great merit of this plate is that it has stood the service for lighting exceptionally well, and some millions of plates are in practical use.

The negative plate is constructed exactly like the positive, but in the future it is intended to use as negative plates, grids filled up entirely as in the Faure method, the grid being shown in Fig. 3. Special care is taken by the Tudor

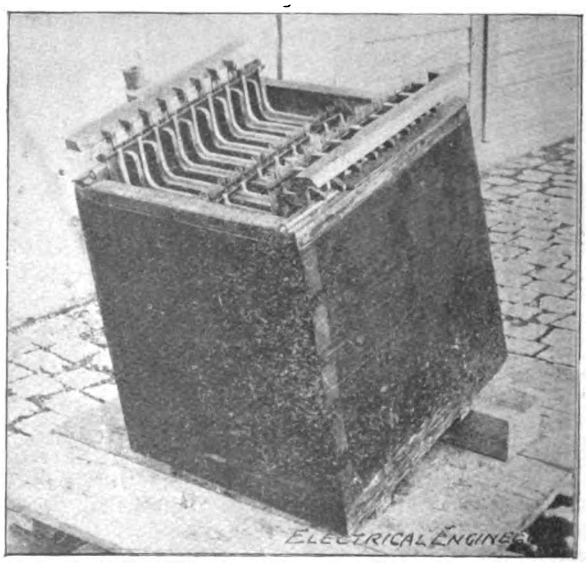

Fig. 6.—The Tudor Cell.

Co. in the building up of cells ; for larger cells, as used in central stations, the plates are shipped and the cells built up at the place of use. The usual way of putting up the electrodes in sections is not employed, but the plates are connected together in series as shown in Fig. 4. The distribution of the current to each plate is more equalized by this means, than by the usual method of connecting the plates in series. When such a series consists of a large number of plates it is found that the middle plates do not work so much as the outer plates. Fig. 5 gives a more accurate idea of how plates for large cells are connected.

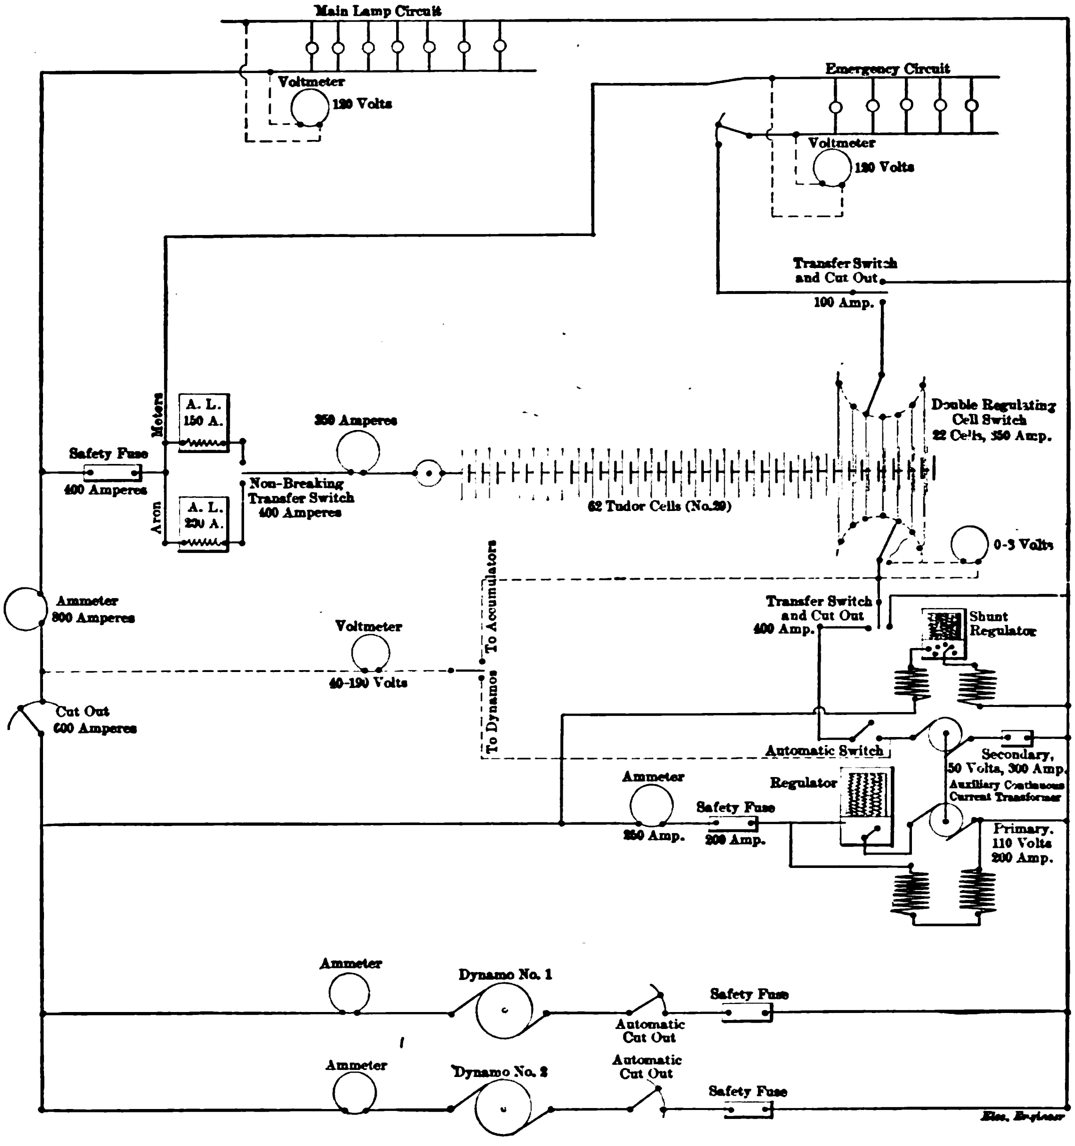

Fig. 8.—Diagram of Circuits of Tudor Accumulator Plant, Zürich, Switzerland.

Fig. 6 shows the present style and workmanship of the Tudor cells; it represents a cell of 500 ampere hours' capacity with 92 amperes charging and 110 amperes discharging current. Its weight, without acid, is 142 kilograms, and it contains 60 litres of dilute sulphuric acid (1.150 sp. gr.) Its cost is about 150 francs (about $30).

Fig. 7 shows a battery, placed in the theatre of the city of Zürich, Switzerland. This battery has a capacity of 1,650 ampere hours, taking a 287-ampere charging current and giving 350 to 400 amperes on discharging, at a potential of 115 volts. Its weight is 430 kilos, and it takes 175 litres of acid per cell. The cost of the whole battery was 25,916 francs (about $5,000).

The connecting of the battery with the dynamos (two dynamos each of 500 amperes and 120 volts) and with the circuits (including about 2,000 lamps) is shown in Fig. 8. The Tudor Company has made a special study of the art of connecting batteries. The principle here employed is to join the battery in such a manner that its valuable power of regulating comes into full play. In the present instance the difference of potential at the lamps during a performance with the sudden changes of light, is not more than 2 volts. During the performance, the battery delivers current, or takes up current, from the dynamos working with a constant power. The charging of the battery is performed by the use of an additional current transformer, which raises the potential of 120 volts up to 155–160 volts at the end of the operation. Automatic regulating devices and a self-regulating amperemeter and voltmeter are added, allowing a perfect and unfailing control of the charging and discharging work of the battery. The efficiency is guaranteed to exceed 75 per cent. (90 per cent. in ampere hours), and the working of the battery is guaranteed for ten years, a yearly payment of $400 being allowed by the theatre company to provide for subsequent renewal of the positive plates.

In case of emergency, this battery is able to provide the whole current for some minutes, and to provide half the number of lamps during the whole performance. A certain number of lamps is constantly used, run by a separate circuit connected to the battery, they being provided in case of a main safety fuse burning out.

It would require too much space to give details about the switchboard, this very important factor in the life of batteries, Fig. 8 merely showing a diagrammatic sketch of connections.

Very interesting and important are the rules which the Tudor Company lay down for the management of their batteries. *Charging* must be carried on even beyond the time when violent development of gases occur, and until *large* bubbles appear at the surface of the cell and at the same time all positive plates appear dark-brown or nearly black. *Overcharging does NOT hurt the cells* and at the end of each charging operation some minutes of overcharging takes place. The complete charging with a little overcharging at the end must be done, whether the discharge has been complete or only partial. The "wonderful amount of care and attention" by which the ENGINEER's informant was so much touched, consists in the following: At the end of each charge the attendant in charge has to go through the battery-room and see whether all cells boil regularly. That is done in a few minutes, even with very large batteries. Should there be a cell not boiling with the others, this cell is examined by means of a glow-lamp with a suitable reflector and the reason is soon found and the cause remedied. "Sitting up all night with it" would prove that the man in charge had not lived up to his instructions but left a cell short-circuited for weeks. In this case the nursing would not help much either, but new positives would have to be provided for that cell.

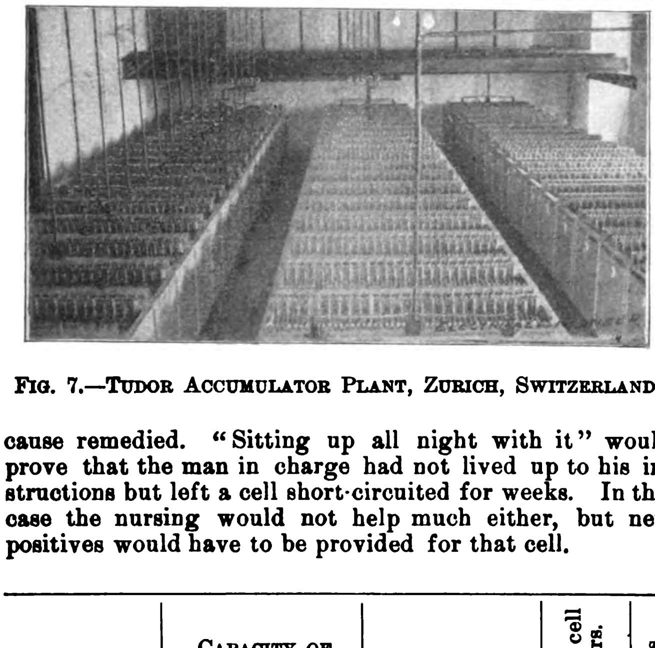

FIG. 7.—TUDOR ACCUMULATOR PLANT, ZURICH, SWITZERLAND.

Name of city.	Capacity of Batteries.		Discharge.		Capacity of one cell in ampere hours.	Number of cells.
	Ampere hours.	Watt hours.	Amperes.	Watts.

LIST OF SOME STORAGE BATTERY CENTRAL STATIONS IN GERMANY.

The Tudor accumulator is manufactured by separate companies in Germany, Belgium, Switzerland, Austria, Italy and France. All these companies guarantee their products in the following manner: The company takes care of the batteries for from one to ten years and guarantees their good working by contract; the customer has to live up to the directions given for each battery and to pay between 5 and 10 per cent. of the value of the battery each year during the term of the contract. The yearly amount of payment depends on the size of the batteries, the kind of work performed by the battery, the distance from the factory, etc. Every three months, an engineer visits all the batteries to see how they are handled and how they are working, and makes his reports accordingly. Automatic devices are, if possible, made use of to control the management of large batteries. After 10 years of service, the company claims that the battery will still have the same capacity as it had at the beginning of its work. Experience with three batteries now seven years in operation seem to justify this claim. The reputation, and practical value of the Tudor accumulator for lighting purposes, has been established wherever it is known. Since some time also portable accumulators are manufactured by the Tudor Companies.

THE SUPPLY OF PLATINUM.

ACCORDING to the London *Journal of the Society of Arts*, there are strata of platinum at Bisserski, in the Ural Mountains, which can alone supply the total quantity of platinum required for the consumption of the world for many years to come. Platinum is found in Brazil and in the Cordilleras, where it occurs in hard serpentine rocks; it is only in the deposits of the Ural Mountains that the metal is found in grains. The richness of the sand in which these grains occur is represented by the figures 17 to 21 grammes of platinum to every 1,640 kilogrammes of sand. Stories are told in the Urals that, when the demand for platinum was insignificant and the price very low, the gold miners who found this metal in grains whilst gold seeking used to use the grains for shot instead of lead for firing at wild birds. All the platinum extracted from the Ural Mountains, after having paid a tax of three per cent. in kind, is sent to St. Petersburgh for treatment and shipment to foreign markets. Throughout the whole world only about 3,000—4,000 kilogrammes of platinum are annually used, but the consumption steadily increases.

AN ELECTRIC CRANE FOR THE BILBAO BREAKWATER.

AN enormous electric crane is to be used in connection with the work on the new $4,000,000 breakwater for Bilbao, Spain. It is constructed especially to manipulate the 100-ton blocks of artificial stone, which are made on the spot. It is built of stout braced steel framework resting on two four-wheeled trucks, the rails upon which it runs being about 18 feet apart. The car is operated by an electric motor taking its current from a trolley wire, the generator being a short distance away. The blocks are lifted by jointed hooks attached to the pistons of hydraulic lifting devices, the hooks clutching a block by means of two bands of iron put into position when the block is in process of manufacture. The blocks are then carried by the crane to the end of the wharf, where they are deposited in a boat and towed out to the breakwater.

ATMOSPHERIC ELECTRICITY.

For some months past M. Mascart has had, says *La Lumière Electrique*, some of his registering electrometers installed on the Eiffel Tower. He does not propose to obtain precise measurements at present, but is only endeavoring to find exactly what use can be made of the Tower for investigations in atmospheric electricity. Under present conditions the instruments are by no means favorably situated for observing the potential of the air; nevertheless, the values obtained are about ten times higher than those obtained at the Parc Saint Maur Observatory, a striking proof of the rapid growth of electric potential with elevation.

INCREASED COMMERCIAL EFFICIENCY AND HIGHER ECONOMY IN CENTRAL STATIONS.—I.

BY

J. H. Vail

Central stations for generating electricity for lighting or power purposes in connection with their systems for distributing and utilizing the same, must be regarded in the light of investments for capital, and their relative values gauged on the basis of dividends returned to stockholders. We may say that electric light and power, as a business enterprise, has passed the infantile stage, and is now regarded as a substantial money-making, dividend-paying investment ready for strong growth, and worthy of confidence backed by substantial financial support, when wisely located, properly equipped, and having the elements of commercial efficiency, permanency, and honest construction beyond question. It cannot be without regret that as a sincere and earnest advocate of the progress of central station business in its best form, I am forced to admit that the majority of such stations in the United States have not creditably withstood the analysis of time, and that a large number of them have been, are being or must be, reconstructed, largely improved, or totally abandoned for new stations in the near future.

It is true that, in many instances, these stations may be called "trial stations," and under this title have served to promote the electric lighting industry and create locally a strong craving for a better operating system, but we will never know how many of them have paid sufficient dividends to warrant their depreciation being rated at 10 per cent., 20 per cent. or 30 per cent., and this large depreciation means that in such instances sham work was originally done and now requires early reconstruction, to enable these stations to continue to perform their daily service with reasonably good economy.

The diversity of opinions heretofore, and even now, existing should be harmonized as to the usefulness and economy of high or slow speed engines, high or low steam pressures, substantial or sham construction, permanency of the business, earning capacity, etc. These have all been sufficiently tested to warrant judicious selections being made for new construction, and these ancestral stations have served a very useful purpose in demonstrating the values of certain types of boilers, engines, dynamos, systems and many other appurtenances, as well as features of mechanical and electrical engineering.

The present dilapidated condition of many stations cannot always be justly charged against the constructing engineer, as it is a well-known fact that in the face of advice to the contrary, the directors of numerous companies have advocated and insisted upon "Cheap John" construction; or in other instances, taken it out of the hands of a competent engineer, placing cheap and inexperienced men in charge, and are now only in justice reaping the bitter reward of such false economy. At other times, unprincipled competition has frequently demoralized the judgment of company officials inexperienced in electrical and mechanical engineering matters, thus resulting in an overwhelming amount of defective construction; the same even occasionally has been performed under the name of concerns having a reputation for good work.

The central station that from an investment standpoint, can at this time afford to continue to spend good money for poor construction because it is cheap, with the inevitable result of having a large percentage of its earnings devoted to constant repairs and maintenance, must be located in a territory exceptionally rich for revenue. It is easy to perceive that if most of the electric construction was of a more permanent character and had cost more money, the stations would have proven to be better investments because of reduced depreciation. Under ordinary circumstances, investors in electrical enterprises cannot be expected to view with equanimity frequent passing of dividends, or a large percentage of earnings annually expended on maintenance and repairs. Let us hope that where extensions or reconstruction are now contemplated, that in the interest of the investor it will always be decided that the work shall be performed honestly and in the best manner to secure permanency and durability, economy and high commercial efficiency.

Recognition must also be given to the fact that of many electric light companies now inaugurated throughout the country, the business of each was originally prospected and determined for a station of moderate size, delivering current within a limited area. The promoters did not realize the possibilities of the business. The present supply of current from these stations, will at once be regarded as very small when compared with the gas output in similar territory. How to promote further growth of the business of each local company, how to reach greater areas for supply and long-distance customers, how to produce the current for less initial cost, and how otherwise to increase the profits of electric lighting and power companies, are to my mind questions of large importance.

We must therefore prepare to do business on an increased scale, supplying from larger power stations electric current for all purposes to all classes of consumers over a practically unlimited territory. I believe these results can be achieved. I believe, also, that larger profits are to be secured by the combination of several methods, such as:

1. Reduction in coal consumption and economy of labor.
2. Higher commercial efficiency of plant and system as a whole.
3. More extensive use of electric light and motive power in districts or area already supplied from station.
4. Ability to supply current for general purposes from a single station over territory of largely increased area.
5. Consolidation of interests where small companies are unprofitably competing for business in the same town.
6. Larger investments, permanency in character of construction.
7. And last, but not least, judicious management of the company's business.

The experience of the past few years has been of peculiar educational value, and the engineer in charge of design and construction of new electric stations, must incorporate such a scientific and practical combination of economical apparatus that when united as a whole will give the highest efficiency.

And just here let us take a valuable and important lesson from the various types and combinations of apparatus applied in central station construction in European cities and towns. The business with them has not progressed as rapidly as with us; they have proceeded with more deliberation. In one feature particularly, they are in advance of much American practice and worthy of our emulation, that is, the first expenditures have been liberal and the initial cost has not been so contracted as to necessitate cheap construction. The general impression received cannot fail to be that durability and permanency have been fully cared for. In some exceptional instances, it appears that science and theory have obtained the upper hand over wise expenditure to such an extent that when the cost of primary generators, plus copper for long-distance transmission, plus motor-dynamos, plus storage batteries, plus copper and line work of distributing system for a small station of, say, 3,000 lights is compared with a direct station system, the investment in apparatus and system for the former, as against the latter, cannot show good net earnings.

Again, there are other stations and systems wherein very valuable features exist, which could well be selected and applied in our American practice, and thereby enhance the value of our investment by increase of dividends. By selecting the best points from foreign systems, and combining them with the most successful features of our own practice we cannot fail to improve over all predecessors. The great redeeming feature that must be a gratification to all persons interested in electrical industries in the United States, is that we have led the world in exploiting the same, and that regardless of the kind of construction, the aggregate of capital receives higher dividends per dollar invested, than can possibly be shown from European stations.

It must be perceived that extreme care as well as large experience is required, to enable the engineer to draw the line so fine as to properly protect invested capital on the one hand, and design a permanent, high efficiency station on the other, that will be exempt from criticism. My comments are not intended to deal with all the questions that would needfully be considered in connection with the above matters, but simply to treat on a few points and present for consideration some leading factors that must be kept in mind before any changes are finally determined upon. I shall therefore try to confine my remarks mostly to the question of generating plant.

ECONOMY IN FUEL.

One of the most attractive methods of increasing profits is to decrease cost of production. This part of the problem leads us directly to the coal pile, and for reduction in coal consumption we must look to our boilers, engines and other component parts of the steam plant. Central station managers and superintendents are having constantly brought to their attention different types of appliances and apparatus recommended as conducive to higher economy. There is a certain craze in the direction of applying these various appurtenances. Salesmen have all kinds of coal saving apparatus and other devices, guaranteeing abnormal percentages in savings. If a record were kept of the promised percentages of savings which these devices are warranted to secure, and the salesmen's promises held good, such record would show a coal saving of over 1ᴜ0 per cent., and the boilers instead of requiring fuel on the grate bars, would become coal producers. Therefore the promises must be largely discounted.

Engineers believe in the practical value of feed-water heaters, condensers, automatic stokers, damper regulators, compound engines, pipe coverings, etc., and yet we know that when all are combined in a single plant, they cannot possibly show collectively such a percentage of total saving in coal as has been claimed for them individually. It is unnecessary to enumerate the large list of miscellaneous appliances introduced and which are often possessed of individual merit. There are many that, while not actually effecting a saving in fuel, aid to secure the more perfect and satisfactory operation of the plant or reduce labor of handling, and must therefore be judged of much value from this standpoint. I would not for a moment discourage the use of these, but rather advise the judicious selection of the best, with the anticipation of a reasonable saving of both fuel and labor as the benefit derived. We should also be cautious in the adoption of too much apparatus of the automatic or self-operating character, lest by lack of necessity for personal care we tend to diminish the vigilance of the engineer, and thus lead to disastrous accidents, because of the automatic device getting out of order. unnoticed.

The application of any special type of engine, boiler or appliance, must be solely on its commercial and economic value for the specific station, system, and local conditions surrounding the same. Expensive fuel will warrant the use of numerous economic devices often requiring large investment, while the same expenditure could not be deemed judicious where fuel is comparatively cheap. Again, in stations of medium capacity, say, from 2,000 to 5,000 lights, there are chances that the interest on the capital expended for higher economy apparatus to obtain better coal economy, may be more than the money value of the coal saved ; therefore, the necessity of competent engineering advice, guided by which should be made the intelligent combination of such apparatus as will secure best economy, so that the results, when compared, may show increased net profit over and above the interest on extra capital invested.

Better fuel economy is to be secured by the judicious application and combination of improved types of apparatus. We must faithfully hunt out and stop every source of waste and apply all reasonable methods to avail of every heat unit, and thus save the steaming value of of every pound of coal. The present fuel consumed in central stations may be assumed as ranging from 3 to 8 lbs. of coal per horse power hour; the higher economy which we may hope to attain may be set at 1.7 lbs. with compound condensing engines, 1.5 lbs. with triple-expansion condensing engines, and 1.3 lbs. with quadruple expansion engines. The coal required for pumping and other incidental service is included.

Briefly on the various points as to how economy of fuel is to be secured, I will say that we must thoroughly investigate the conditions surrounding and covering the location of a proposed central station plant. The first cost of coal, its delivery in the station, the steaming qualities of the coal and the percentage of refuse, must all be carefully ascertained. The plant must incorporate boilers of the highest evaporative efficiency, also such appliances as will secure the best results from the coal obtainable. Such a system of piping as will permit a free delivery of steam from boilers to engines; engines of such a type and economy as will give the highest results from steam used. Condensers should be applied, where conditions will permit, feed-water heaters, covering to reduce surface condensation, and appurtenances to save and utilize every unit of heat.

Another matter which is receiving but little attention in central station practice is the absence of any method for utilizing the heated air of the boiler and engine-room as hot-air supply to the furnaces. A large amount of heat is developed that is generally wastefully disposed of by free ventilation at the ceiling of the boiler-room. This heated air can be availed of as a hot-air supply to the furnaces with some percentage of economy, and at small cost can be raised to a higher temperature by additional circulation. The minor sources of wasted heat, if carefully followed up and remedied, will, when all summed up, result in a considerable net saving in fuel. All of this can be accomplished at small cost, and improved economy, still securing ample fresh-air ventilation.

HIGHER STEAM PRESSURES.

Where the construction of a new station is contemplated it will readily be recognized that the boilers, steam piping and other appurtenances connected with the steam plant, can be arranged to carry the higher pressures required for operating compound condensing or triple-expansion condensing engines; but where the reconstruction of an existing station is intended, it is of great importance that a thorough inspection be made of the boilers, steam piping and all adjuncts thereof, with a view to ascertaining whether all are of sufficient strength and in serviceable condition to carry safely the higher pressures required. Pressures of from 80 to 100 lbs. should be used for compound-condensing engines and from 140 to 160 for triple-expansion engines.

For quadruple-expansion engines, we must calculate to carry a steam pressure of 200 lbs. per square inch. To do this, we must have boilers, piping, fittings and other appurtenances ample in strength for the higher pressures required. Efficient and durable lubricants must be secured to stand the increased temperatures; thus far, these lubricants cannot yet be considered as satisfactory. When these difficulties are overcome, we may anticipate the use of quadruple-expansion engines in stations of exceptionally great capacity, where very heavy constant loads can be carried for many hours. We must, however, be content to wait and see the engine developed and the station reach an output where the constant large load will warrant the extraordinary investment.

A NEW STANDARD BALLISTIC GALVANOMETER WITH VARIABLE SENSIBILITY AND WITHOUT "DRIFT."

BY

Elmer G. Willyoung

THE galvanometer which I am about to describe is the product of considerable study and careful tests. It became necessary a number of months ago for me to design a good ballistic galvanometer, and several were built and experimented upon in order to obtain the best operation and results. A great many tests were also made upon the instrument in the laboratory in connection with routine work, the instrument having been used in every day practice by various persons for a number of weeks. This, of course, is one of the hardest kind of tests to which an instrument could be subjected. The law of deflection, the leakage, the decrements of damping with coils open and closed, with coils short circuited and in series with various resistances, were all obtained. Various modes of suspension and of constructing systems were tried; in particular a considerable time was devoted to the study of different methods of varying the sensibility of the system, and some important conclusions were drawn.

The instrument which has been finally produced as a result of these various tests and experiments is shown in the engraving, Fig. 1. I will first call attention to the general plan of the instrument. The coils are two in number and equal in size; they close upon the magnetic system, which hangs in a diameter between them, and are supported upon highly polished and corrugated hard rubber pillars. These pillars are 2$\frac{7}{16}$ inches high and, since the corrugations are sides of equilateral triangles, they are equivalent to plain pillars of just twice the surface, or about 5 inches high; the surface resistance to leakage is, therefore, very great. Upon the rubber pillars are brass rods joined at the top by a cross bar which carries the torsion head and its suspension. The suspension is, when in position, a trifle over 2$\frac{3}{4}$ inches long. The torsion head is divided into 15 degree divisions and by its means the coefficient of torsion of any suspension may be quickly obtained.

The coils of this instrument are of the graded type, the number of changes of wire which have been made in the grading of the coils being five. The exact position of each of these various sizes has been determined by mathematical calculations working from the actual data of commercial wires and the best results in the way of thickness of insulation which we have been able to obtain. A special frame was used in the winding of these coils, as with all coils put on galvanometers made by Messrs. Queen & Co. This frame enables us to accomplish the grading correctly and with great facility. The core of this frame is of steel of a very small diameter so that very little of the valuable space at the centre of the coil is lost. The sensibility of these graded coils, wound according to calculation, was to the sensibility of coils wound in the usual manner as 9 to 4.

The clearance between coils in this galvanometer was made but $\frac{1}{20}$ inch, leaving just room enough for the system to turn in. The instrument has been so made that the coils may be connected together by means of light flexible connectors, R seen in the engraving, so that they may be used either singly, in multiple, in series or differentially. In case a still greater range is desired, the coils may be removed and other coils substituted, they being made strictly to gauge and interchangeable. The binding posts screw into little studs attached to the coil's end, and are surrounded by light rubber washers D, where they pass through the case. These washers prevent dust and dirt getting inside the case when the instrument is not in use but are withdrawn when it is desired to use the instrument, so that the binding posts are always insulated from the base by the hard rubber pillars.

Levels have been left off the instrument as the writer has come to the conclusion that the level is of no practical use to the majority of those having to do galvanometer work, the instrument being usually leveled up until, by inspection of the mirror, the system is seen to swing freely. In order to quickly inspect the system the coils are pivoted so as to be easily thrown open by merely removing the binding post rods and raising the milled screw clamp V.

What I want to call particular attention to in this instrument, however, is the method of controlling which is employed. This method of control is, I believe, new and is applicable to all instruments in which the moving system is made up of one or more magnets. It is the invention of Mr. Edwin F. Northrup, of Messrs. Queen & Co's. laboratory, and is, I believe, one of the most important additions to galvanometer practice which has been made for a long time. The improvement consists in a means of varying the sensibility of the instrument within the widest limits in an exceedingly simple way and in a manner which entirely does away with some of the annoying inconveniences and sources of inaccuracies which have been experienced heretofore when using instruments of this character. As is well known, the usual method of varying the sensibility of instruments of this type is by neutralizing the earth's field to a greater or less extent by means of the exterior "control magnet" attached to the frame of the instrument. This method of varying the sensibility has been the source of a difficulty, the cause of which has not always been comprehended and which has been exceedingly annoying and has caused many inaccuracies and delays in work. This trouble is familiar to most galvanometer users as the "drift" of the needle.

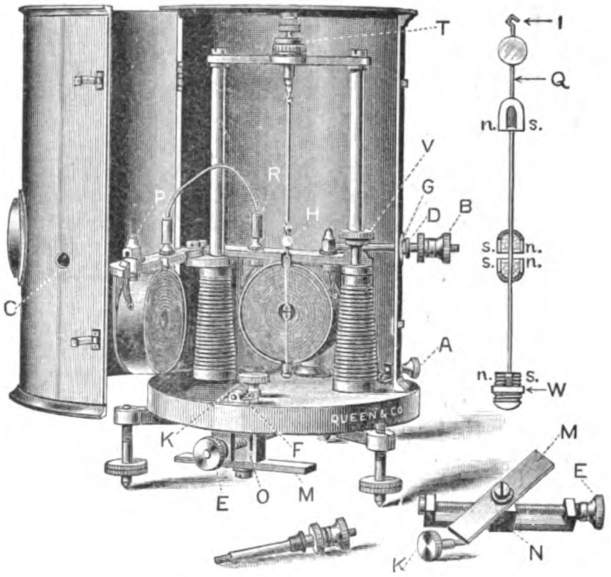

FIG. 1.—NEW STANDARD BALLISTIC GALVANOMETER.

Let us conceive a case of a system composed of two sets of magnets B and D, Fig. 2, the upper set composed of four magnets with their north poles pointing in one direction, and the lower set composed of three magnets, of the same length as the upper set, and with their poles pointing in the opposite direction: this combination is known as an "astatic" system since the controling force of the earth's field is only the difference of the magnetic moments of the two systems. In the case supposed, the upper set "controls" and the N poles of the upper system will point to the north. If now we wish to make the system still more astatic we weaken the earth's field upon the upper needle be means of a control magnet suitably placed near it. We now have the magnetic system subject to the influence of two fields, one, the earth's, and the other the field of the control magnet. We may represent these two fields in strength and direction by lines suitably drawn; let us also suppose that these fields are placed to oppose one another but with planes not rigidly parallel. Fig. 3 shows this with A B representing the earth's field in strength and direction, and A C that of the control magnet. Completing the parallelogram, we obtain A D, which represents the resultant field in direction and intensity.

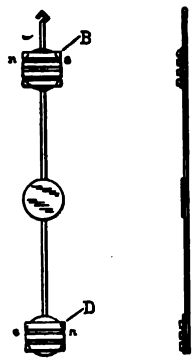

FIG. 2.

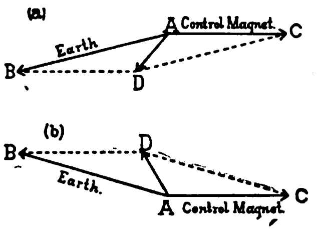

FIG. 3.

Let us suppose now that the earth's field slightly changes in direction as is shown in *b*, Fig. 3. The resultant now points nearly directly opposite to its first position, and though the earth's field has moved through but a small angle, we see that the resultant will have moved through nearly 180 degrees, so that the slightest shifting of the earth's meridian causes an intensely magnified movement of the resultant.

There are none of us, probably, working with galvanometers, but who have experienced this annoyance. After some time spent in adjustment, we finally get the mirror nicely to zero, when in a few moments we look again and find some other number on the scale before us, and if we keep our eye at the telescope it is possible to see the mirror of the scale moving across the field of the telescope. These changes are obviously greater in proportion to the sensibility of the instrument; the mirror is never still, going one way and then another. The fluctuations are, of course, more pronounced at some periods of the day than at others, owing to the fact that the earth's meridian is changing at a more rapid rate at different times during the day. This difficulty necessitates a frequent adjustment of our instrument and causes a great deal of delay in the attaining of results.

By the device of Mr. Northrup's, all the annoyances of "drift" are eliminated, the instrument is rendered much more certain in its indications, besides being less expensive to construct. Reference to Fig. 4 will show the principle of this device. At (*a*) is an ordinary horse shoe magnet at the bend of which is a bar of soft iron A B; the distribution of the lines of force is practically unaltered by this bar. In (*b*) we have the same magnet but with the bar moved about half way up towards the poles; the lines of force are now considerably deformed and many have been drawn down so as to pass through the soft iron armature. In (*c*) the same armature has been pushed up to the very poles and almost all the lines are now passing through it, the magnet thus being short circuited and made about as ineffective, as regards its external field, as would be a mass of soft iron of the same shape. Now let us look at the magnet system shown to the right in Fig. 1 which represents the system used in this instrument. The system is seen to be composed of four "bell" magnets of the well known Siemens type; the upper and lower have their poles turned in the same direction, while the centre magnets have their poles also in the same direction but opposite to that of the outside magnets. The upper and lower magnets thus make up one set of an ordinary astatic system and correspond to the set B, Fig. 2, while the centre magnets correspond to the set D.

The outside magnets are, as will be noticed, slightly longer than the inner ones and will, consequently, if all are magnetized in practically the same way, be the stronger and will "control" the system. If now we weaken one or both these outside magnets their control will be lessened and the period of the system will be increased until finally the influence of the inner magnets will begin to predominate and the system will swing round through 180 degrees. The means by which this weakening is accomplished are in this instrument very simple. The lower magnet has cut upon it a very fine screw thread, and upon this thread is fitted a narrow and light ring of soft iron, W. When the ring is at the bottom of the magnet its influence is nil; if we desire a greater sensibility we simply screw the ring up until this sensibility is attained. In order to do this easily the system is attached to the fibre by means of an exceedingly small hook, I, and may readily be removed by simply lifting it off with the aid of a small pair of forceps, when the ring may be moved a trifle, the system replaced, and the vibration period observed; in practice, all this can be done in a very few minutes.

It might be objected that in thus short-circuiting this outside magnet we lose a portion of the deflecting moment of this magnet which is, of course, acted upon by the coil. This is true, but the loss is very small, the effective couple upon these outside magnets being vastly less than that of the inner. The best proof, however, is the result, and some of the results obtained with this instrument are given below. Using the old method of control, that is, an exterior control magnet, we had:

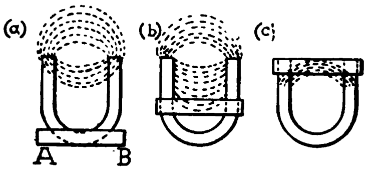

FIG. 4.

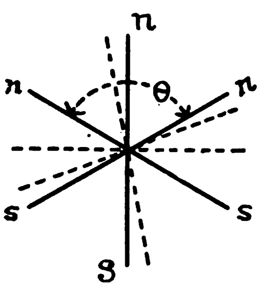

FIG. 6.

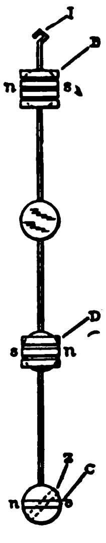

FIG. 5.

Period (single swing)	$4\frac{17}{25}$ seconds.
Mean deflection $\frac{1}{5}$ M. F. at 1.44 volt	100 mms.
Drift in 5 minutes	2.5 mms.

With Northrup's Method:

Period (single swing)	$11\frac{1}{10}$ seconds.
Mean deflection $\frac{1}{5}$ M. F., at 1.44 volt	211.5 mms.
Drift in 5 minutes	Inappreciable.

And making it still more astatic:

Period (single swing)	21.6 seconds.
Mean deflection $\frac{1}{10}$ M. F., at 1.44 volt	237 mms.
Drift in 5 minutes	Inappreciable.

The large vibration period of over 40 seconds for a complete swing obtained without "drift" is extraordinary in my experience. It may readily be made very much greater, however, and the instrument correspondingly more sensitive by this method. The ring, instead of being screwed on, might, of course, be held on by its friction. Indeed, in the first set constructed, the ring was so made. It may, of course, also be applied to the upper instead of the lower magnet, or, indeed, to both, if desired. It may also be applied to the orthodox system in a variety of ways; for instance, one of the sets of magnets of an ordinary Thomson system might have a little sheet of iron arranged so as to slide up and down on the shaft of the system, thus short-circuiting, more or less, the magnetic lines of force of this particular set of magnets; or we might extend the shaft of the system on below the lower pair of coils, and here place a single small magnet acting with one of the regular sets of magnets of the system, and thus controlling the system. On the back of this might be a little piece of soft iron of about the same size as the magnet, and pivoted so that when parallel with the magnet the lines of force of the latter would be almost completely short-circuited, but when perpendicular to the magnet it would be very little influenced. This mode of application is shown in Fig. 5, the dotted lines indicating the little piece of soft iron.

The system used in these extremely sensitive galvanometers of the Thomson type is required to be so extremely light in order to be efficient that the slightest additional weight is to be deprecated; the actual weight of the systems as made in the best instruments being slightly less than 350 mgs., including the mirror. I have not yet, therefore, succeeded in making a system embodying the improved method of control which is satisfactory to me. The instrument shown in Fig. 1 has, therefore, an exterior control magnet, M, used only when the light system is required; when used for ballistic work this magnet is entirely removed from the instrument by merely loosening the milled head K.

As regards the construction of the system used in this ballistic instrument, considerable pains have been taken to work out one thoroughly adapted to the requirements; its moment of inertia is extremely large, the little magnets (Fig. 1) being filled with lead in order that this may be so. The magnets being cylindrical there is minimum damping due to air friction. The magnets are threaded upon a little quartz rod Q; the weight of the whole system is 4½ grammes. Quartz is used for a support for the system, rather than glass or metal, on account of the set of the latter material.

Experience in galvanometer construction has taught that the well-known set in glass and metallic wires is productive also of "drift" if they are used as supports of a system of magnets. This is illustrated by Fig. 6, where A B and C D represent two magnets of equal length, placed one above the other on the shaft so as to make up an ordinary astatic system. The magnets, as seen here, are at a slight angle to one another, it being practically impossible to place them in the same plane; the resultant of these two magnets must, of course, lie within the angle θ. If now there is any set in the shaft, upon which these magnets are mounted, which is slowly working itself out, the relative position of these two lines will change and the plane of the resultant will consequently be shifted. This, of course, will cause "drift" of the needle.

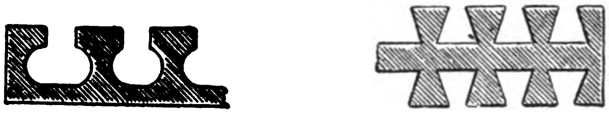
The fibre intended for use in the instrument is a very fine quartz fibre, having soldered to its ends exceedingly small hooks corresponding to the small hook on the torsion head and to another one on the system itself. In this way the system is very easily removed either for adjustment of its little control magnet or to be replaced by a light system for ordinary work.

A BIOGRAPHICAL SKETCH OF THE KHOTINSKY ACCUMULATOR.—VI.

BY

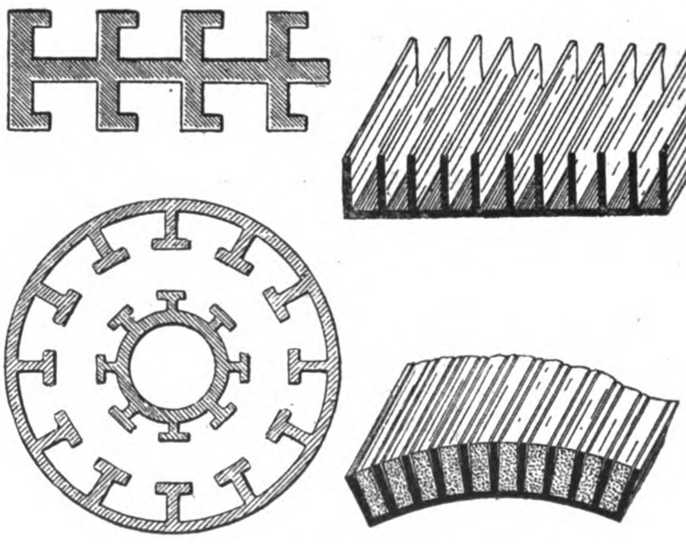
Capt A. de Khotinsky

In January, 1885, I went to Cannstadt with six cells of my battery, which had been made for this station in order to have them tested by Professor Dietrich. From the report of Professor Dietrich and especially from the successful results of my horizontal accumulator in the block station at Rotterdam, my company now found it time to go before the public with the accumulator. The company, aware that for years to come the question would be the improvement of accumulators, saw that they would need security for the durability of the accumulators without risk to themselves. An order for a station for arc and glow lamps followed from the Frankfurter Company in Frankfort-on-the-Main, which was put in operation in the winter of 1885 and fed 230 glow lamps and six arc lamps.



FIGS. 18 AND 19.

In November, 1885 I went on my company's order with six cells of my horizontal accumulators to Vienna. The Imperial Continental Gas Association in Vienna had undertaken the electric lighting of the Imperial Court Opera by accumulators. Herr Albert Ritter von Obermayer, Imperial Major, professor at the Technical Military Academy, was charged by this company with investigating my accumulators. Several orders from different countries in Europe were now received and filled as a result of this investigation.



FIGS. 20, 21, 22 AND 23.

Up to the winter of 1885 I used flat wooden trays, the insides of which were lined with canvas coated with a preparation of tar. It was always impossible for me to procure adequate trays of glass or other insulating material which at the same time would be acid proof. In Rotterdam these wooden trays proved very good, but in transporting them the shaking loosened the coating of tar and leakage ensued. I remedied this by lining the wooden trays with lead and placing between them and the lead a preparation of tar. To insulate the positive electrodes I put them in small flat troughs of hard rubber, while the negative electrode rested on the lead tray, which also served as the negative electrode. The small hard rubber troughs used for holding the positive electrodes were expensive and had the disadvantage of breaking as soon as the positive electrode commenced to expand.

During the construction of the first battery of horizontal accumulators, I had, as the most convenient construction, and also for possibly augmenting the capacity, devised an electrode skeleton of pressed lead, with a projection at the end of each rib to prevent a falling out of the filling material from the middle ribs and the framework walls, as shown in Figs. 18, 19, 20, 21. Applications in all countries for a patent on this construction had already been made in the spring of 1885, but I had great difficulty in finding a lead factory which was able to deliver to me the described skeleton. Finally, however, I succeeded in getting at least one skeleton delivered like that shown in Fig. 22, and at once used this to dispense with the small hard rubber troughs while, for the sake of insulation from the lead lining, I put them on paraffined sticks. But experience soon proved that a one-sided electrode curved like an arch by the expansion of the filling, as in Fig. 23. After several unsuccessful attempts I finally succeeded in finding a little lead factory in Holland which was able to deliver to me an electrode skeleton of pressed lead, such as I wanted. This first electrode skeleton is represented in Figs. 24, 25, 26 and 27. In December I could form accumulators of large capacity up to 600 ampere hours per element, with the assistance of this electrode, as in Fig. 28.

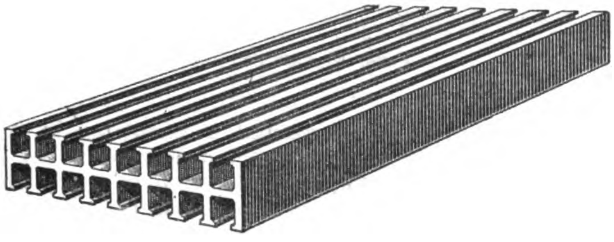


FIG. 24.

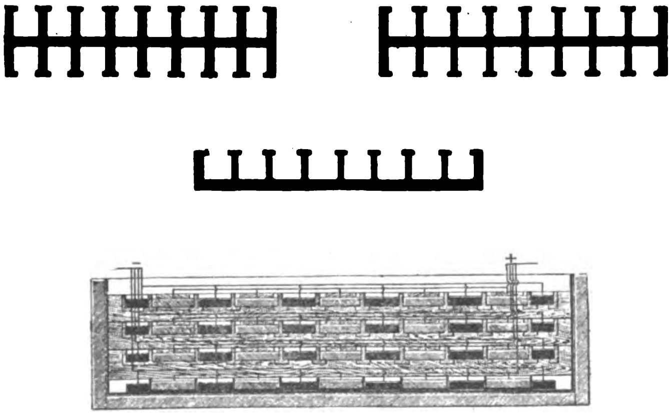

FIGS. 25, 26 27 AND 28.

In the spring of 1886, the Electro-Technic Factory, at Cannstadt, commenced to use my accumulators for lighting railroad cars in accordance with my system, and a growing interest in the accumulators appeared in Germany. In the meanwhile I had established a factory in Rotterdam, as the sale of my glow lamps had greatly developed.

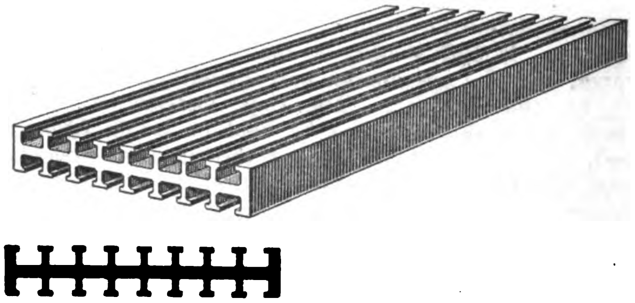

FIG. 29.

As their good quality was now well recognized, my company decided that I should give my whole time to the manufacture of the lamps, and I therefore gave up my manufacture of acumulators and turned it over to the firm of Gottfried Hagen, in Cöln. By taking these measures I gained also the savings of freight and import duties from Holland to Germany.

In the year 1887 I was charged with the erection of a new block station in Neue Friedrichsstrasse W. 37, in Berlin, which had to be constructed for Mr. L. W. Schöffer. It was determined, in this station, to prove that my glow lamps of high voltage (160 volts) and also the combined system of accumulators with dynamos was capable of supplying a complete system of distribution and could compete with gas distribution on every point. The project included 1,200 glow lamps of 160 volts and 16 c. p. It was required that in case of necessity the accumulators should be able to supply with current 1,200 lamps for only three hours and that the battery in normal action must deliver in six hours its whole capacity of 1,200 ampere hours. Up to this time I had only made cells which could discharge their whole capacity for eight hours. I could easily have solved the problem by slower charging and discharging of these cells (Type L), as is still done at all other accumulator factories, but I aimed to avoid the inevitable waste of material connected with this course and therefore sought to work out a new electrode for rapid charging and discharging (Type R). To reach this result, I had only to resume the experience of relative enlargement of the contact surface of the electrodes, already made, and according to these principles I made a skeleton as shown in Fig. 29 for a positive electrode and in Fig. 30 for a negative electrode.

EXHAUST STEAM HEATING AT CEDAR RAPIDS, IA.

THE AMERICAN DISTRICT STEAM COMPANY, of Lockport, N. Y., have completed about a mile and a half of mains for the Cedar Rapids Electric Light and Power Company, and now have steam on the line. They are already heating over 1,000,000 cubic feet of space with three pounds pressure in the heating mains.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 208 *Broadway, New York City.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can 'entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XIV. NEW YORK, NOVEMBER 16, 1892. No. 237.

In working for discovery, it is requisite to experiment first and then seek the interpretation.—John T. Sprague.

CLOSING THE WORLD'S FAIR AT NIGHT.

ONE of the most important questions, lately, in connection with the World's Fair, has been that of closing or opening it at night time. It is stated that the management proposes to close the Fair at 7 p. m. each day, putting into force a rule that has been adopted provisionally, among others, by the National Commission, having to do with the police regulations of the grounds, etc.

If there is any likelihood—which we can hardly believe—that the Fair will close at the hour when it can be made most attractive, we beg to enter at once our most emphatic protest against any such proceeding; and, if it is insisted on, we advise dynamo and lamp manufacturers to abstain from exhibiting. In Chicago, the argument is made that it will prevent the local workingmen from seeing the Fair, as their spare hours are mostly in the evening. This may well be, but such a view is simply local. Early closing of the Fair would be a most serious matter for the workingmen from all parts of the Union, whose leisure is scant, whose spare dollars are very few, and who will not be at liberty to spin out their visit to Chicago over several days. If the Fair closes at 7 p. m., it means to them the loss of at least three solid hours daily, with the sacrifice of much of their intellectual pleasure and technical profit.

But there are other grave considerations. It is estimated that the electrical exhibits will run into millions of dollars in value, and the largest part of this money will be spent on apparatus for light and power. Are we to believe that this apparatus is to be idle just at the moment when it can best illustrate its benefits as an addition to modern means of convenience, comfort, economy and beauty? If so, electrical manufacturers have been fooled and played with. It would be interesting to know where and exactly why such an idea as this originated, of shutting down the electrical exhibit just when it would be most effective.

Moreover, the Fair itself will be most brilliant as a night spectacle. Even if all the buildings were not kept open, there would be some to which access could be given, and which everybody would reserve as "choice mouthfuls" for the remaining hours of a memorable day. And then the grounds and lagoons would be at their best under the arc light, with bands playing, and the wonderful electric fountains illustrating anew the birth of light itself.

It seems to us that the management, if serious in such a proposition, forget the obligations into which they have entered. Many of the concessions awarded have, to our knowledge, been based by the lessees on calculations that included several hours after sunset. Besides that, a great many of the State buildings have made special plans and arrangements for artistic electric illuminations. Are we to understand that this expense has all been incurred for nothing, on a deliberate misrepresentation? Of what use would these decorations be in the day time? The Fair authorities have themselves also gone to enormous expense for electric lighting. The contracts for lighting include about 100,000 incandescent lights for the buildings and about 5,000 arc lights for the grounds. A huge generating plant has also been ordered, and much of the work has actually been begun or even done. This represents more than $500,000 of public money that might at least have been saved if it was not intended to keep the Fair open after 7 p. m., for very few, if any, of those lights would be needed in the daylight hours between May and October; and it certainly would be sheer and criminal extravagance to make such an outlay merely for half-a-dozen special spectacular evenings. One leading object of the Fair authorities, having made such liberal provision of current, should, on the contrary, be to stimulate the larger exhibtors to new and original displays of decorative electric lighting, and thus to emphasize the great fact that light has to-day become, equally with color and drapery, an element of the beautiful and æsthetic.

We feel very much like saying that, after all, this is just what we feared. When Chicago first got the Fair, and a building was devoted to Electricity, and the air was full of enthusiastic talk, it really seemed as though the world was going to witness the illumination of all Lake Michigan, backed by a display of about ten billion lights in the Fair buildings and grounds. Gradually and gradually, the dream has been sobering down into a dismal reality, and now we find that there is virtually to be no electric illumination at all. Once more, we protest. In the name of the electrical exhibitors; of the various concessionaries for all sorts of privileges sold at fabulously high prices; of the authorities who have ordered elaborate illuminations for State buildings; of the workingmen and modest wage earners of America; and in the name of all others interested in seeing the Fair, and in getting quickly back home again—we protest. If the Lord Almighty walked in his fair Garden of Eden in the cool of the evening, we want to know why his creatures are to be forbidden the same privilege in the fairest Garden that American genius has ever laid out.

UNIPOLAR DYNAMO CONSTRUCTION.

BY

Edward C. Boynton, Jr. M.E.

It appears to the writer that the recent articles in The Electrical Engineer upon "Twisting Magnetism" while they may, or may not, have succeeded in explaining that interesting phenomenon, have done considerable towards "twisting" the fundamental laws governing electromagnetic induction.

Suppose one were busily engaged in trying to devise a unipolar dynamo, and eagerly searching for "points;" where would he be after reading the various opinions recently expressed? One writer supports his own theories, another believes exactly the opposite. The different interpretations of these "familiar laws" are astonishing, and this is probably one of the principal reasons why we do not get a successful high-voltage unipolar machine. The interest in the so-called unipolar dynamo is far greater than is generally supposed. It is probably not an exaggeration to say that nearly every electrical engineer, at some time has turned his attention to this class of dynamos with the hope of devising one that is commercially practicable.

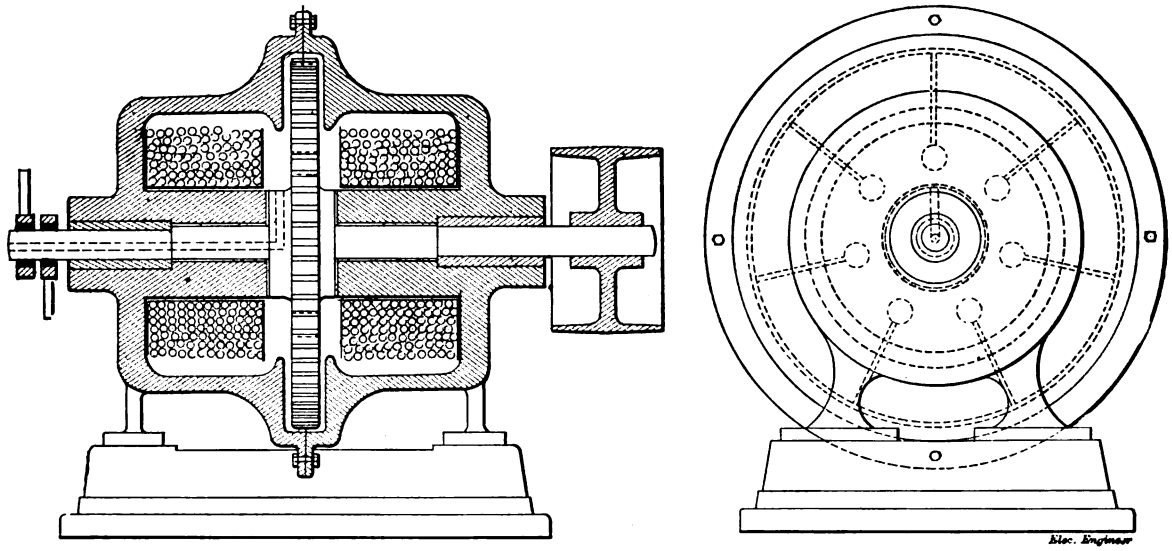
Very little has been written on the subject heretofore, and it is almost impossible to get information concerning the experimental work that so many have devoted to it. In consequence, many failures are probably being repeated. In order to intelligently study the unipolar problem one must be able to correctly interpret some of the laws governing the relation between the electric current and a magnetic field of force, known as induction. These laws are laid down by various writers with more or less lucidity, and it is difficult at times to keep from being misled by their language.

The theory of the generation of current in a unipolar dynamo is exactly the same as in a bipolar or multipolar machine. The statement in a recent letter to the Engineer to the effect that the current in a bipolar dynamo is due to the "increase and decrease of the number of lines of force passing through the circuit of which the moving conductor forms a part, etc.," the writer does not believe. That the statement is founded on one of Prof. Thompson's laws every one is aware, but with all respect to that eminent authority, from whose books the writer has gained more information than from any other, this law seems at times to be superfluous, especially when the generation of current can be explained by another law with far more clearness.

If a conductor be moved at a constant speed through a perfectly uniform magnetic field, at right angles to the direction of the lines of force, a perfectly smooth uniform current in one direction will be generated in the conductor if its circuit be closed. If the density of the field of force be not uniform, but is more dense at one point than another, the current in the conductor will be undulating in character, but will flow in the same direction at all times. The whole problem of the unipolar dynamo is to use a number of these conductors, and to close their circuits so that they will be all in series.

The interesting part of the problem is to connect them in series *outside* the field of force. If this is not done, the lines of force will cut the same circuit a second time, causing a reversed current, and thus completely neutralizing the current in the circuit. There are at least two methods of making these connections outside the field, and the writer regrets that he is not at liberty to give them at present.

Almost the only law necessary to constantly bear in mind in studying a unipolar dynamo or in trying to "wind" the armature for one, is that which is commonly illustrated by the thumb and two adjacent fingers of the right hand, pointing in three different directions at right angles, showing the direction of the line of force, the direction of motion of the conductor, and the direction of the current induced in the conductor. Probably the better illustration is that representing the three co-ordinates of space, for one can be made out of cardboard and the circuit of the armature conductors followed by it in such a manner that it can be readily seen whether the current will reverse at any point in the circuit.



Figs. 1 and 2.—The Boynton Experimental Unipolar Machine.

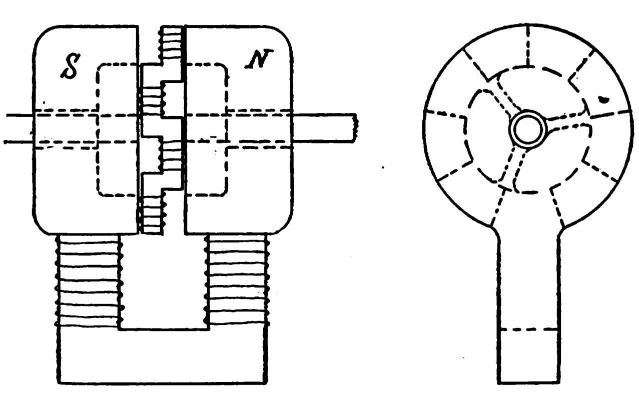
Magnetism certainly will not "twist" in the sense the writer of the original article meant. Why it will not, some one else must explain. If the core of a bar magnet be rotated about its longitudinal axis, no matter whether the energizing coil be rotated with it or not, the lines of force are practically stationary and do not rotate with the core. If the armature of an ordinary bipolar machine, "D" type, be left bare and the wire, instead, be wound around the pole-pieces, outside and through on the polar surfaces, parallel to the shaft, then if the armature be rotated and magnetism *would* twist, the lines of force would stick out around that armature like the bristles on a hog's back and would cut the conductors on the pole-pieces beautifully. But on the contrary, it is well known that the lines of force through that armature are stationary, and rotating the armature does not move them.

Although we do not know exactly what "lines of force" are, in considering the problem it is as well to assume that we have to deal with but one line of force, which extends entirely around the magnetic circuit, and compare it to something tangible, like a piece of elastic. It can be stretched by the motion of the armature more or less, but always snaps back to its original position, and is practically stationary.

It will be noticed, as one proceeds with the study of these machines, that in most all cases, one or two sliding magnetic joints (a rotary slide) seem an absolute necessity, a method of construction which has its defects, but when balanced against the hysteresis and loss from eddy currents which should be entirely absent from the successful unipolar machine, it may not result in a great drop in efficiency. It is also probable that the armature itself will form one pole of the magnetic circuit. Both these features are included in the construction of the machine shown in Figs. 1 and 2. This machine was built for experimental purposes with the idea of altering its construction as fast as new experiments demanded. It could not recognize itself now.

The point is, of course, to wind the armature. The person conducting the experiments concluded that in its original form, as here shown, it would be rather a difficult problem. Perhaps some fellow-worker would like to try it. In this machine the whole outside frame is of one polarity and the armature a consequent pole of the opposite polarity. The armature has a number of holes bored through it near the centre, from each of which extends an open slot to the rim. It also has its outer edge toothed, merely to facilitate the winding.

The machine, of which two views are shown, Figs. 3 and 4, is rather interesting because, at first sight, it looks as if it ought to work. The pole-pieces are circular, the plane of the circle being at right angles to the shaft. They are hollowed out in the centre so that two rings of opposite polarity are presented to the armature. The later is roughly shown and is a sort of Gramme ring carried by a non-magnetic spider attached to the shaft. The rim of the armature is of iron and divided into sections, which extend first to one side and then to the other. The winding is radial, the wire all in one piece, and the alternate sections wound in opposite directions.

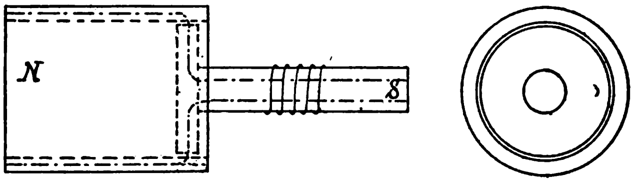


Figs. 3 and 4.

It is easily seen that if the lines of force would enter the armature at the points where it is nearest the N pole-piece and leave it where nearest the S pole-piece, the currents induced in the conductors would be in series. But they will not all go that way, at least when the armature is in motion.

Fig. 5 shows a round bar magnet with a disc at one end, inserted a short distance into a hollow iron cylinder. Suppose the magnetic circuit to be completed in any convenient manner, then the lines of alternate dots and dashes show the paths of the magnetic lines of force. If now we revolve the bar magnet about its geometrical axis, will the lines of force emanating from the edge of the disc and entering the cylinder revolve with the bar, or not? The writer believes and experimental work seems to carry out that belief, that they will not so revolve.

If this be true, it would seem to settle the question that magnetism will not "twist" when a bar magnet is revolved about its own axis. But there are other ways of moving magnetism so that it apparently twists, but in reality does not.



Figs. 5 and 6.

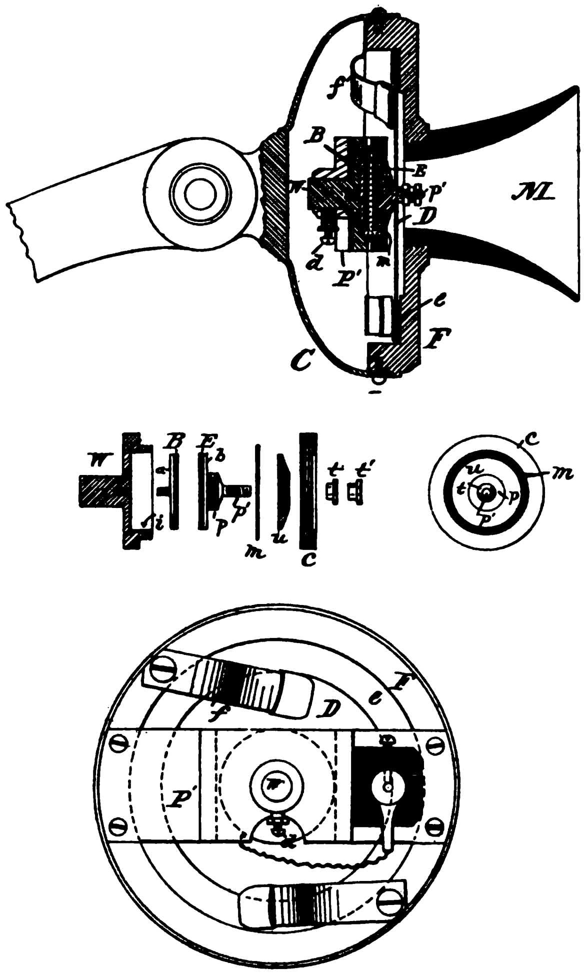
THE "SOLID BACK" LONG-DISTANCE TELEPHONE TRANSMITTER.

When the American Telegraph and Telephone Co., familiarly known as the "Long-Distance Company," began operations, the need for a more powerful transmitter than the Blake became apparent, and the Hunning type was resorted to. After considerable experimenting, the company adopted a form of transmitter having a horizontal diaphragm with the mouth-piece curving downward and forward, so that the air vibrations impinged upon the lower side of the diaphragm. It was confidently expected that with this construction, the "packing" of the granulated carbon would be avoided, and large numbers of these transmitters were put in use. It was found, however, that in time the carbon granules did become compacted, so that the transmitter required frequent tapping in order to give proper articulation. As soon as this fact became apparent, the company set about to improve this vital element in their system, and the result was what has been termed the "Solid Back" transmitter. This instrument, which has made the Chicago-New York telephone line a commercial possibility is the invention of Mr. Anthony C. White, of Boston, and its construction will be readily understood from the accompanying engravings, Fig. 1 showing the instrument in section and Figs. 2 and 3 illustrating the construction of the granular button in detail. Fig. 4 is a rear view of the transmitter.

In this instrument it will be seen, the sound receiving diaphragm D, is attached directly to the disc E constituting the front or working electrode. B is a disc constituting the heavy back electrode, and P is the finely-divided conducting material between the electrodes. A heavy metallic block, W serves as a casing or frame for the electrodes and the finely-divided conducting material, being chambered to receive them. The finely-divided material, as in other instruments of the button type, is anthracite carbon, and the two electrodes E and B are discs of carbon.

As the two transmitter electrodes must of necessity be insulated from each other, it might at first sight appear that convenience of construction of the casing W would dictate the use of an insulating material such as ebonite or wood. But as stated above, this shell is made of metal, brass being employed whose coefficient of expansion is substantially the same as that of the electrodes. The walls of the chamber in the block W are lined with gummed paper I, to prevent the short-circuiting of the instrument.

It will be observed that there is a considerable space around the periphery of the two electrodes E and B to receive the finely-divided conducting material out of the direct path of the electric current. The finely-divided material in this part of the chamber not becoming so much heated in the operation of the instrument as the portion between the electrodes, the latter portion is permitted to expand into the former and so offer less disturbance to the electrodes, due to its change in temperature. Moreover, this construction prevents the clogging of the finely-divided material between the working electrode E and the walls of the chamber W that takes place when that electrode substantially fills the chamber, thereby interfering with the proper movement of the electrode. The carbon electrode B is secured to the back on the bottom of the chambered block W by means of a brass disc *a*, soldered to the electrode and secured into the block. The front electrode E is soldered to a similar disc of brass *b*, which by a threaded boss or pin *p* and nut *u* is secured to the inner face of a mica disc *m*, that in turn is clamped to the sides or rim of the chambered block W by a threaded sleeve *c*, secured upon the block as shown, and serves to confine the finely-divided conducting material within the chamber of the block. The flexibility of the mica permits the front electrode E to have a piston-like movement in the chamber.



FIGS. 1, 2, 3 AND 4.—SOLID BACK TELEPHONE TRANSMITTER.

The entire button, it will be seen, is secured by a set-screw *d* to a heavy brass bridge-piece P′, whose ends in turn are set into the metallic frame F of the receiving diaphragm, which, with its dampening and insulating ring is held in place by means of padded springs *f*. The frame F is set in a metallic cup-shaped outer casing C.

The instrument just described is rapidly displacing the former horizontal type, and the results obtained with it would seem to indicate that "packing," that great bugbear of granulated carbon transmitters, has at last been successfully overcome.

THE CINCINNATI DISTRIBUTING TELEPHONE POLE.

BY

W J Robinson

IN keeping with the best practice of to-day, according to which all overhead telephone wires in crowded city streets are dispensed with, the Cincinnati telephone company some time ago began the work of putting their wires underground. While this in itself is a simple problem, the connection of a large number of subscribers to an underground system is by no means an easy task and must of necessity involve some overhead work in order that the cost of making connections may be brought within reasonable limits.

In order to accomplish this object the Cincinnati company has adopted a method, which embodies a number of advantages, and which the writer believes, possesses a number of novel features.

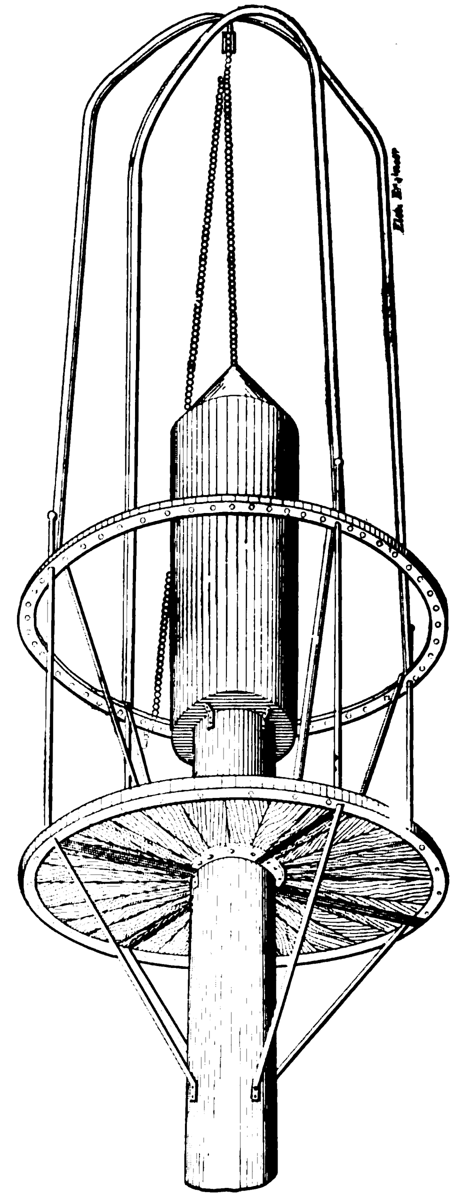


FIG. 1.—CINCINNATI DISTRIBUTING TELEPHONE POLE.

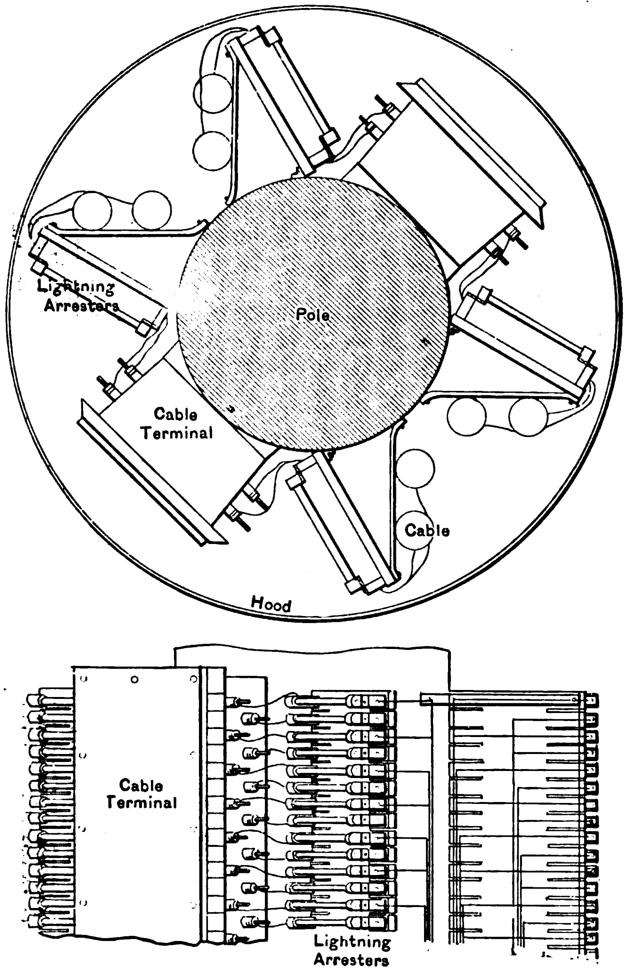
For the purpose of connecting subscribers to the underground system, distributing poles are employed which are placed in the alleys, one in the centre of each block to distribute the telephone wires to adjacent houses without crossing any of the main streets. Instead of a cable box a water-tight hood is employed. This construction was adopted for the reason that the doors of cable boxes are very apt to warp and admit rain and snow, besides which the connections are so closely compacted that difficulty is often encountered in making repairs.

In the Cincinnati pole, however, as shown in Figs. 2 and 3, connections are made inside the hood, and the lower rings and bars carry the platform for the workmen. The four iron posts that hold the distributing ring in place and the four braces, which raise and lower the hood by means of a chain and block, are also shown. The hood is adapted for fifty or one hundred pair cables, as two fifty pair cable heads can be placed under the same hood if desired, one on each side of the pole. Two strips of lead fuse arresters, one on each side of the cable head are used. The wiring from these to the cable head will be straight work, and that from the other side to the distributing ring will be in thirteen-pair Okonite cables made especially for this work. These cables will come out at the bottom of the hood and go down through the floor of the platform to the iron posts and the distributing ring, from the under side of which they radiate in all directions to the various telephones in the block. The wire used from the ring to the houses will be Okonite, $\frac{4}{32}$, with an insulation resistance of 500 megohms to the mile.



Figs. 2 and 3.—Cincinnati Distributing Telephone Pole.

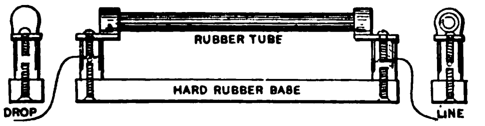


Fig. 4.—Lightning Arrester.

THE ELECTRIC ARC.[1]

BY R. S. DOBBIE.

The lecturer introduced his subject by referring to the early experiments of Sir Humphrey Davy, performed near the beginning of the century, but which had not been turned to practical commercial use until the invention of the direct current dynamo made possible the cheap generation of current. The experiment of Davy was shown, and attention drawn to the fact that the arc, which gave the name to the light, was only present when the carbons were in a horizontal position, whereas when they were in a vertical plane the bending of the arc does not take place. It was then shown that the principal source of illumination in the arc had its seat in the crater of the positive carbon, owing to the far greater heat developed at that point, as compared with that at the tip of the negative carbon. This the lecturer demonstrated by showing the condensation of the carbon vapor upon the cooler negative electrode, and the building up of the latter under certain conditions of the arc. It was also demonstrated by the fact that if a carbon positive and a copper negative electrode be employed, the carbon is deposited upon the copper electrode.

Mr. Dobbie also referred to the fact that the presence of air was not necessary to the pointing of the carbon, as the effect takes place, though in a lesser degree, when oxygen is excluded. Neither did the presence or absence of any gas affect it to a very noticeable extent.

The lecturer then demonstrated that it was possible to maintain the arc under water, the gases liberated by electrolytic action producing the effect of violent boiling. In this experiment the ends of the carbons remained practically square. In further proof that the principal seat in the arc lay in the region of the positive carbon, the lecturer described the experiments of Prof. Sylvanus P. Thompson, who explored the arc and showed that of the total difference of potential between the two carbons nearly nine-tenths was included between the tip of the positive carbon and a space barely one-hundredth of an inch from it.

Mr. Dobbie drew attention to the fact that the nature of the carbon had considerable influence on the quality of the arc, a bad carbon making it almost impossible to obtain a satisfactory light, no matter how good the regulating mechanism might be. In order to account for the brilliancy of the arc, it was well to remember that in an ordinary arc lamp from one-half to a full horse power was concentrated at a very small point.

Of the various methods to steady the arc, the author laid special stress on the cored carbon, and he showed on the screen an arc formed with such a carbon as the positive.

He next passed to the causes which might interfere with the maintenance of the arc, such as drafts of air, and showed how easily the arc could be blown out. He also demonstrated the action of an electromagnet on an arc, the effect of which also was to blow it out. The application of these principles by Prof. Elihu Thomson, of blowing out, first on the commutator of the Thomson-Houston arc machine, and then as a lightning arrester with magnetic blow-out, was touched on.

The lecturer then referred to the arc produced by alternating currents, in which both carbons were equally consumed, and in which the distribution of light was evenly divided, the same amount coming from each electrode. While to the eye an alternating arc might appear to be continuous in its nature, its alternating character could be demonstrated by rapidly passing a brilliant object in the vicinity of the arc, a reflection of which was seen by the eye. When this is done, the momentary impressions caused by alternate changes in the brilliancy of the arc are clearly shown by a series of images of the object, instead of a continuous streak of light, as would be made with a continuous, uniform quality of light.

Coming to practical arc lighting Mr. Dobbie remarked that to produce a steady light requires a properly designed generator, a good arc regulating mechanism, and finally a good carbon. He referred briefly to the fact that the arc generator must be so designed that a diminution of current increases its E. M. F.; otherwise what is known as "pumping" of the lamps would occur.

He then described more than 20 different types of arc lamp mechanism, illustrations of which were thrown on the screen from the lantern, and drew attention to the fact that some of the arc regulators made nearly 40 years ago, were quite able to maintain fairly good regulation. He laid stress on the fact that whereas formerly arc lamp mechanisms were designed with a view of maintaining the current constant, the modern arc lamps were built to maintain the potential difference constant.

At the conclusion of the lecture Mr. W. J. Hammer showed a number of photographs of high-potential arcs representing potential differences varying from 50,000 to 150,000 volts, and also a photograph of the first arc lamp made by Mr. William Wallace, nearly 30 years ago.

---

[1] Abstract of a lecture delivered before the N. Y. Electrical Society, at Columbia College, Nov. 10, 1892.

ELECTRIC RAILWAY DEPARTMENT.

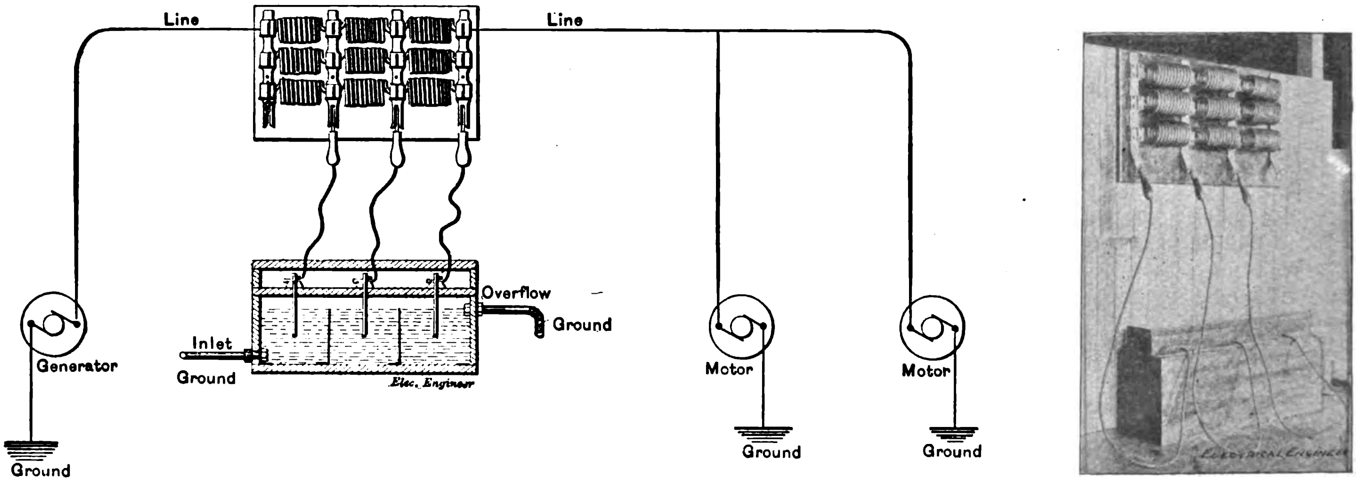
THE TANK LIGHTNING ARRESTER AS AN ADJUNCT FOR STREET RAILWAY POWER HOUSES.

BY

Alexander Jay Wurts.

THE modern electric railway plant is of such broad dimensions and represents such a large capital outlay, that any interruption in its service must seriously curtail net receipts, not only through the actual loss of fares during the hours of enforced idleness, and during which time, of course, expenses are still running apace, but also through loss of public confidence.

In many of our cities and towns, particularly in the Western sections of the country, it has been common practice during thunder storms to shut down the plant, pull down the trolleys and wait till the storm shall have spent itself. In one case, with which I am familiar, the direct losses from enforced idleness during thunder storms amount to over $6,000 per year. The value, therefore, of an efficient and reliable lightning arrester for the protection of street railway apparatus cannot be overestimated.



FIGS. 1 AND 2.—THE WURTS TANK LIGHTNING ARRESTER.

So far, the ordinary spark gap arrester has proved of value, in that it has, without question, saved many thousands of dollars worth of property. There is, however, a difficulty in connection with lightning discharges which is not usually recognized, and which, with ordinary spark spark gap arresters, is very difficult to avoid. The theory of such discharges, which observation in many cases has proved to be correct, is, that the discharge is much more likely to occur at some points in the line than at others. An arrester may, therefore, be connected to the circuit at an ineffective point (called a nodal point) and the discharge may pass the arrester and take place at another really vital point in the circuit, which, in many cases, will be the generator.

It is not an easy matter to clearly explain to the average central station man why static discharges do not readily pass through coils of wire. The simplest scientific explanation would involve technicalities which it is my desire to avoid. There is, however, one simple way of pointing to this as a fact. A trolley wire is connected to earth through the generator and motor armatures by unbroken copper conductors of large carrying capacity. Why, then, does a trolley wire need lightning arresters at all? Why do not the static charges at once pass to ground through the armature coils? Or, in other words, Why do these discharges pierce the high insulating material of the armature and jump to the frame of the generator or motor when the wire on which this charge already exists is so well grounded? It is because *static charges do not readily discharge through coils of wire,*—through the coils of an armature. The charge forces its way partly through the armature coils, and, being greatly impeded in its progress (by inductive resistance) there results what is technically known as "side flash" through the insulation to the iron frame of the generator.

The best path for the discharge is one in which it is not required to pass through a coil, and in which the resistance is low. The ideal arrester, therefore, should tend to prevent the accumulation of the charge on the line; it should afford a number of paths of low resistance from several points of the circuit and it should offer a high resistance to the passage of static charges from the line to the armature.

These requirements are admirably met by the "tank arrester," which consists of a coil of wire connected in the main circuit with several discharge circuits leading from different points in the coil to electrodes immersed in a tank of water, the latter being connected to the ground. This arrester is particularly adapted to the protection of street railway generators. Its construction will be readily understood by referring to the diagram, Fig. 1, the apparatus itself being shown in Fig. 2.

The coils, made of No. 0000 copper wire, are nine in number, arranged three in series and three in parallel. The current capacity of No. 0000 wire is about 300 amperes, so that the capacity of the entire set of coils may be varied by any multiple of this number. The set shown in the engraving has a capacity of 900 amperes, and is mounted on a backboard, the dimensions of which are 32 x 20 inches. The tank is of wood, lined with galvanized iron, and its dimensions are 32 x 28 x 10 inches. The three electrodes are ordinary flat arc light carbons held in simple clamps, and the method of connecting these to the coils is clearly shown. The inlet is, of course, connected to the city main and thus forms the best possible ground connection for the tank. The coils are connected in series with the station ammeter, and when thus connected, will stand guard over the entire station. The action of the combination is as follows:

All charges which may accumulate on the trolley line or feeders will be forced to pass through the coil before reaching any of the generators. The function of the coil is then to cause the fatal "side flash" to occur *there* rather than in the coils of the armature, and this is the more readily accomplished from the fact that there are several low-resistance paths from this coil to earth without the necessity of piercing any insulating material or jumping over the smallest air space. In other words, there is an exceedingly difficult path for the lightning discharges to reach the generators, and an extremely easy path for them to reach the earth. Furthermore, the fact that the line is directly connected to earth without the intervention of the air gap, offers a constant drain through which the static charge may dissipate itself, that is, the charge need not accumulate on the line till its intensity is sufficient to jump the spark gap of an ordinary lightning arrester.

Dynamo leakage is, of course, to be expected, and during the first stages in the development of this arrester the leakage was so excessive that the scheme would have been abandoned had it not been for the fortunate discovery that this leakage was reduced about 70 per cent. by the use of running water. With running water fed through a ½-inch pipe at ordinary city pressure the leakage amounts to 6 or 7 amperes at 500 volts. But in consideration of the almost certain protection that the arrester will afford, this loss of power sinks into insignificance, and in fact the leakage need only occur during thunder storms, as the discharge circuits may be cut out at other times by pulling the plugs shown in the engraving.

The advantages of this arrester may be summarized as follows:

1. The presence of the coil in the dynamo circuit, which prevents the discharge from passing to the dynamo and forces it through the tank. 2. The opportunity for constant leakage of the charge, by which the accumulation of a charge sufficient to break through the insulation of the generator is avoided. 3. The numerous discharge circuits connected with the coil which secure facility for discharge from a number of points, thus avoiding with certainty the nodal points of the circuit. 4. The avoiding of a short circuit on the generator at the time of a discharge, and the possible injury to the generator or the opening of the circuit breaker. 5. The affording of paths to the ground, avoiding the use of coils or inductive circuits in the discharge path and securing low ohmic resistance. 6. The fact that one arrester will protect all the generators in the power-house.

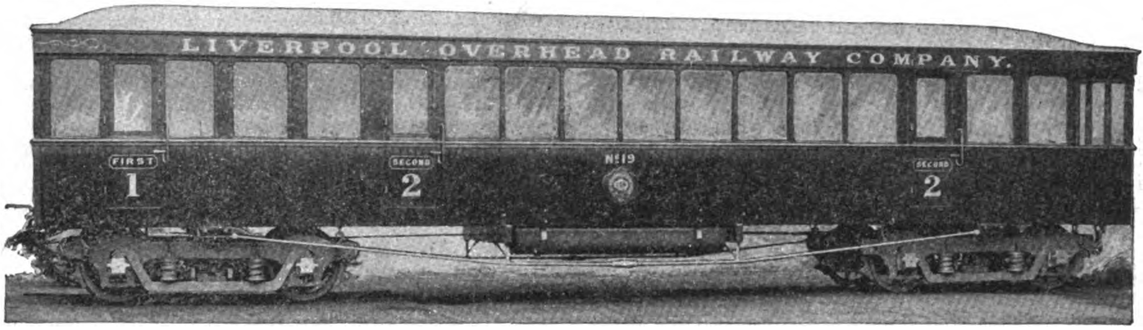
A number of these arresters have been in use during the past season in various sections of the country, and those who have reported their experiences write in unqualified terms regarding the wonderful protection afforded by this arrester.

THE BALTIMORE-WASHINGTON ELECTRIC ROAD.

The traction syndicate plan for a road between Baltimore and Washington will be enlarged and the road extended to Philadelphia. The company has been incorporated under the laws of Maryland as the Washington and Baltimore Boulevard and Electric Railway Company. The incorporators' act requires that the work on the road shall begin within six months and be completed within 24 months after the passage of the act. It is proposed to run trains at the rate of 60 miles per hour. The fare from Baltimore to Washington will be 25 cents. This is the largest electric railway project on foot in the country to-day.

THE CARS FOR THE LIVERPOOL ELEVATED ELECTRIC RAILROAD.

We have already published some details about the elevated electric road which Liverpool is soon to have, but may repeat some of the details. It will run parallel with the docks a distance of about six miles, with sixteen stations very much after the New York model. It is to be worked by electricity, generated at a power house about the middle of the line. At this station are four engines, each capable of working up to 400 in licated horse power, and each driving an Elwell-Parker dynamo of the familiar vertical, consequent pole type. The current will be carried by a steel conductor, placed on porcelain insulators, supported upon cross-timbers between the rails of each track. Hinged collectors of cast iron, sliding upon this conductor, will make the connection. The motors are not placed upon a separate locomotive, but are carried by the passenger carriages, one of which is shown in the accompanying illustration, for which we are indebted to the *Railroad Gazette*.



Car for the Liverpool Elevated Electric Railroad.

Two carriages, each seating fifty-six passengers and provided with a motor at one end, will constitute a train. The carriages are to be so coupled as to give a motor at each end of the train, and the motors will be so connected together as to be controlled from either end by the driver, who will always change ends upon arrival at a terminus. The driver will carry a key, without which the motor cannot be operated. All the carriages will be alike, but they will contain compartments for two classes of passengers. A train loaded with passengers will weigh about forty tons. The carriages will be lighted by electricity and fitted with the Westinghouse brake. The speed is to reach a maximum of from 20 to 30 miles an hour. The total cost of this railway, including equipment, will not exceed $425,000 a mile.

ELECTRIC RAILWAYS AT TORONTO, ONT.

The amended proposal of the new electric street railway company has been accepted, and the old street railway company given thirty days in which to accept the bargain. By the arrangement with the new company the work of building the track must be begun between November 15, 1892, and March 15, 1893. Seven miles of the railway must be completed, and the electric cars running thereon within two years. At the end of twenty years the city may, after six months' notice, assume the ownership of the railway on payment of its value, to be determined by arbitration. The company will pay yearly to the city $100 per mile of single track and $205 per annum per mile of double track, if the gross receipts of the railway are $60,000 a year. The company will also pay on all gross receipts under $100,000, 5 per cent.; between $100,000 and $125,000, 5½ per cent.; between $125,000 and $150,000, 6 per cent.; between $150,000 and $175,000, 6½ per cent.; between $175,000 and $200,000, 7 per cent.; over $200,000, 8 per cent.

BONDING ELECTRIC RAILWAY TRACK.

BY

A. K. McCay.

I HAVE read the excellent paper of Mr. R. L. Warner on the "Resistance of Return Circuits in Electric Street Railways," in last week's issue of the ENGINEER, with great pleasure, and heartily agree with him in every respect. I am glad we have had some actual experiments in this line and we can now count on the resistance of the return circuit as more or less a known quantity.

I would call attention to one particular point in tables B and C, namely, that there is an appreciable difference in the resistance when the ground is wet, as we all know. I had occasion to improve the return circuit of a certain railroad not long ago and placed heavy copper plates 18 x 14 inches in two streams which were over a mile apart but which flowed directly into the same river; these plates were bonded to both rails with No. 4 copper wire; the result was very appreciable and the saving in coal was quite considerable. The track referred to was bonded with No. 6 galvanized iron bonds 28 inches long and cross-connected at every other rail. There are a great many roads crossing streams where this method could be used, and I am sure, to advantage. The thanks of electrical engineers are certainly due to Mr. Warner for this exhaustive article.

AN INSTITUTE DISCUSSION ON ELECTRIC RAILWAYS.[1]

THE discussion was opened by DR. CARY T. HUTCHINSON, who took up the subject of "Series Traction," and first referred to the pamphlet issued in 1888, by the company exploiting Prof. Sidney H. Short's system of series traction, in which it was sought to prove that this method possessed enormous advantages over the multiple arc method of operating railway cars. Dr. Hutchinson showed the errors in this pamphlet, one of the most glaring being the assumption of the loss in conductors, and the cost of that lost power. Instead of Mr. Short's assumption that it cost $12.00 a day for coal to run the electric car, in multiple, it was demonstrated that the actual cost was but $1.00 a day.

Referring specifically to Mr. Perry's paper, Dr. Hutchinson agreed with the author that the thing worked beautifully on paper, but the employment of movable switches with magnets to open and close them, with trolley wheels for them to run on and connect three wires at the same time in many cases, etc., appeared to put this system beyond the pale of practicability. Another point to be considered was the fact that to run a large number of cars would require enormous potential differences. As a single dynamo cannot be constructed to give over 5,000 volts, it would be necessary to divide the line into sections, which would have to be very short for city work and would involve more switches. Mr. Perry seemed also to have neglected the fact that a constant current motor was a very different thing from a constant potential motor. While the latter could be run at double its nominal capacity for a short time, a constant current motor at once comes to a dead standstill if the load is greater than that for which the machine is designed; in other words, it had no margin of overload. Such a motor for street car work would therefore have to be built for the greatest load which it could possibly get, and again the regulation of such motor would require either the variation of the field, or the shifting of the brushes, the latter of which would cause sparking. Besides, the series system is necessarily a double trolley system, which of itself would condemn it. While it was true that the series system has somewhat the advantage in saving of copper, the cost of copper, although a large item in its self, was by no means the total cost, and the reduction of copper cost to one-half or one-fifth its present value would not be sufficient to counterbalance the other disadvantages entailed in the series system.

Regarding the "Electric Railway Motor Tests" made by Prof. Shephardson and Mr. Burch, Dr. Hutchinson remarked that they were evidently made with crude apparatus, and some of the conditions of the tests were not accurately specified. He drew attention to the waste occurring by the use of the 5th and 6th clip in the regulating rheostat with a Sprague No. 6 motor, and compared some of his tests, published in THE ELECTRICAL ENGINEER, of Oct. 12, 1892, with those of Prof. Shepardson. In these tests electrical methods were used entirely, in contradistinction to mechanical measurements. The curves showed that a No. 6 motor had an efficiency of 83 per cent. at 20 amperes, falling to 80 per cent. at 35 amperes, and running down in the other direction to 80 per cent. at about 12 amperes. That was to say, between 10 and 35 amperes the efficiency at the armature shaft is above 80 per cent. The efficiency with the gears with 35 to 15 amperes is fairly constant at about 75 per cent. These tests showed very much better efficiency and better results in every way than any which he had seen published except some which were distributed at the recent meeting of the Street Railway Convention, at Cleveland, relating to the new Short gearless motor. The claim was made that this motor reaches a maximum of 87 per cent. at 7½ h. p., and is practically constant up to 14 h. p. The efficiency from 5 to 21 h. p., averages about 83 per cent.

Dr. Hutchinson drew attention to the important remark in Prof. Shepardson's paper that an average of 12 tests on a road showed that with two motors on a car it required 27 per cent. less current than when only one was working. The explanation was to be found in the fact that with two motors, each motor was working at lighter loads, and consequently at lower efficiency.

As to the comparative value of the rheostat and commutator methods of field regulation, Dr. Hutchinson thought the matter could be definitely decided by submitting the result of actual tests. He submitted a table showing the comparative efficiency, which showed that in every case the commutated field method gave an efficiency higher even than the electrical efficiency with rheostat, and much higher than the best probable value of the actual efficiency.

Coming to Mr. Leonard's paper on the new system of electric propulsion, Dr. Hutchinson admitted that it possessed the property of allowing the car to start very easily, and the current would not rise above the value of current required for moving the car, and also running at any speed, and on any grade, without the great waste caused by using up the difference between 500 volts and that which is applied to the terminals of the driving motor. Dr. Hutchinson, however, did not agree with Mr. Leonard's calculations as to the relative power required to operate cars by that system, and by the usual method. He figured that with Mr. Leonard's system an efficiency of 33 per cent. would be reached, as against 54 per cent. calculated by Mr. Leonard. With the same driving motor governed by rheostat, an efficiency of 19 per cent. would be reached, while with the commutated field method it would be 27 per cent. The difference between 33 and 27 per cent., that is, 6 per cent. was too trifling to compensate for the complication involved in Mr. Leonard's system.

Regarding Mr. Leonard's claim that his system would permit of a reduction in power equipment, Dr. Hutchinson referred to the fact that it was based on the assumption that railway managers would be satisfied with a speed of three miles per hour on heavy grades, which was not to be entertained in this day of rapid transit. He also gave a table of tests as given by Mr. Leonard, and one calculated by himself, which showed the cost of equipment per car to be $7,430, as against $4,200, the present cost, and as against $3,430 calculated by Mr. Leonard. Reference was also made to the much greater weight of the Leonard equipment.

DR. CHAS. E. EMERY remarked that in all brake equipment, the apparatus ought to be very closely criticised, and he showed how errors might very easily creep into such measurements. On the subject of the variable speed gear, which Mr. Leonard had sought to work out electrically, he had sought to solve the problem by mechanical means, by the employment of a pump with variable capacity to drive a hydraulic motor fixed on the axle. Other workers in the same field had proved that it was necessary to stop frequently to allow the liquid to cool off. A car equipment on this principle had been constructed near New York. Dr. Emery thought that Mr. Leonard had a strong competitor in the shunt motors recently built by Siemens Bros. & Co., and operating the new locomotives on the City and South London Electric Railway. Their use was only made possible by building the motors heavy enough, with plenty of iron in the field.

MR. C. O. MAILLOUX referred to the great facility for regulation afforded by the use of the storage battery in electric railway work, which was, in fact, one of its strongest points. One of the readiest means it afforded, was to divide the battery into groups, to run in parallel at the start, and then gradually group them into different arrangements for series, multiple, and so on. By this means a variable electromotive force was obtained as in Mr. Leonard's system, but without his machinery. It also allowed of the ready operation of the motors at starting, and their coupling in parallel later. Mr. Mailloux believed that the method of using batteries in parallel with motors at the same time was first tried by himself on Fourth avenue, in 1887.

Regarding variable speed devices, Mr. Mailloux did not think that the extra complication overcame the other objectionable features. He had tried an epicyclic gear train for this purpose, but had abandoned its use as it introduced additional levers, which the motormen oftentimes operated in the wrong way.

MR. FRANK J. SPRAGUE referred to his experience at Richmond five years ago, where twenty cars were run with multiple series switches used with the commutated fields, they worked perfectly as far as the slowing down of the machine, etc., was concerned; where it failed was when, on heavy grades, the attempt was made to run the machines in series, or when stopping on a slippery track. One motor would then begin to race and the other would slow down, if there was slipping on the track on account of ice or sleet, or from any other cause. He was much amused by the claims made for the series multiple regulation; as to its effectiveness there was no question, but the series multiple system when running at full service would make little difference in the coal burnt. The result was that he abandoned the series multiple switches, and ran the machines invariably in multiple.

---

[1] Abstract of a joint discussion on Oct. 25, 1892, of the papers read at the General Meeting of the American Institute of Electrical Engineers, Chicago, June 8, 1892, on "Series Electric Traction," by Nelson W. Perry; a "A New System of Electric Propulsion," by H. Ward Leonard; and "Electric Railway Motor Tests," by Prof. Geo. D. Shepardson and Edw. P. Burch.

Mr. Sprague stated that in the latter part of 1886, he had supplied Mr. Wharton, of Philadelphia, with motors to be operated by storage batteries, which were grouped in various combinations with the motors also arranged for multiple series grouping of both armatures and fields. It was found not to be very satisfactory because so complicated.

PROF. F. B. CROCKER, referring to Dr. Emery's remarks on the employment of shunt motors on the City and South London Railway, stated that the conditions there permitted of their use, as trains there normally run at full speed with a clear track, the only time at which they ran slow being at the starting. This mode of operation was diametrically opposite to that of ordinary surface street car practice, and hence precluded the employment of such motors on surface roads. He had early recognized the objectionable features of dead resistance for regulating motors, and in 1884 was one of the patentees of several devices for commutating fields.

DR. EMERY, in reply, stated that the Siemens motors referred to showed an efficiency of 90 to 92 per cent. for a variation of speed between 12¼and 30.6 miles per hour, as tested by brake in the shop.

MR. CHAS HEWITT stated that shunt motors for street cars had been not entirely neglected in this country, and it was certain that the original was not made by Siemens & Halske. He thought that Mr. Sprague had tried it in the early days. One of the objections to the employment of the shunt motor on railroads was the constant breaking of the circuit caused by the jumping of the trolley, due to unevenness of the trolley wire. With a shunt motor, every time the trolley leaves the wire the shunt field is discharged, and when the trolley strikes the wire again, a short circuit through the armature occurs. He was under the impression that in London they used the third rail in addition to a top-running trolley wheel so that the contact is ensured at all times. As the whole tendency of street railway practice was towards greater simplicity, he doubted the practical success of Mr. Leonard's system. He did not think that the difference between the two motors was due so much to low efficiency as to the difficulty of making two motors run together, so as to divide the loads equally between them. The matter had been simplified recently by giving each motor a distinct circuit.

MR. MAILLOUX stated that he had always operated motors with an independent circuit for each.

MR. FRANK J. SPRAGUE was of the opinion that series electric traction was now a thing of the past, and might be allowed to rest in peace. While improvements were being made in the perfection of apparatus in electric railways, he was of the opinion that little, if any, increase in actual economy had been attained over that of the early roads. Four years ago 40 cars were running on the Richmond road with engines of 375 h. p.; in other words, 9 h. p. per car at the central station. Indeed, he thought that in some things we had retrograded, such as in the additional complication of apparatus, which gave the motormen too much to think of.

Mr. Sprague thought that when considering the time limit involved in starting with Mr. Leonard's system, the amount of coal burnt in the central station would be fully as great as, if not greater than, that with the system of direct supply, owing to the energy needed for the continuous rotation of the power converter. Regarding the employment of Mr. Leonard's system for elevator work, the same time element entered, but in a far greater degree, as in the case of an elevator the period of rest to that of actual duty was in a far greater ratio, and in Mr. Leonard's system one machine would have to be kept in constant operation, taking current no matter whether the elevator was in operation or not. In 1886 he had operated two shunt motors on an elevated railroad in New York. The speed of the car was controlled first by the rheostat, and second by the variation in field strength, the energy of the car being thrown back to the line in slowing. Later he introduced the series method of regulating machines. Considering the fact that with the shunt motors, a certain amount of energy can be returned to the line, he questioned very seriously if the shunt motor would not hold its own in time on a great many lines of street car service.

DR. HUTCHINSON, speaking of the power per car required to operate a line, referred to a case in Baltimore, where a grade of 6 per cent. was mounted at a speed of eight miles an hour. Here 60 h. p. equipments were employed. A single car on that road averages 205 miles daily, probably the highest on record, the rest making 190 miles. Tests made on that line showed that the horse power per car, measured from the engine, the cars being equipped with old Sprague double reduction motors, amounted to $6\frac{3}{10}$ indicated h. p. minimum, and 8 h. p. maximum. These measurements, which were made two years ago, would, if made to-day, probably show anywhere from 12 to 19 indicated h. p. per car.

MR. MAILLOUX believed that the time was soon coming when the value of storage batteries in taking care of the large fluctuation in loads at railway power stations, would be recognized, and that no engines had yet been devised which thoroughly accomplished the object.

MR. SPRAGUE referred to the increased economy to be obtained by direct connected dynamos. He was of the opinion that for large railroad work it was essential that there should be at least two, and possibly four, motors in operation. The series system would be used for running at variable speeds, and the machines would be compound wound. He was now concerned with others in building an electric locomotive of about 700 h. p. which would have four motors of 175 h. p. each. In the work on the locomotive now being designed by the General Electric Co., for the B. & O. R. R., under the original Thomson-Houston plan, they would probably use four or six with various combinations.

MR. H. WARD LEONARD stated that accurate tests of his system had been made by W. Sellers & Co., of Philadelphia, and that the efficiencies shown in his table had been quite well borne out. He did not think that 6 h. p. at the central station would be enough with every car in operation simultaneously, but that it represented the average per car, some being at rest, others going slowly, going down grade, etc. As to the cost of his system he did not consider it an important factor, because in a railway installation which he was equipping, the actual cost of the car equipment was only five per cent. of the cost of the complete work. Practice has shown that the attention required by the apparatus in his system was practically nil, and the machine being entirely sparkless, required no attention for months at a time. This system also had only one lever for the motor men to operate, which would give all speeds, reverse, and apply the braking action to the car. Under normal use no mechanical brakes would be required. With this system, when the speed was sufficient to require the entire 500 volts on the line, the switch would apply it directly, and thus avoid the transformation and loss hinted at by Dr. Hutchinson, the motor being shunt wound. As to his system in elevator work, sufficient trials had been made to enable him to say that its efficiency was well known. A traveling crane to be erected at the World's Fair, perhaps the largest ever constructed, will be so operated, and the use of the system on passenger elevators will be thoroughly tested in the new *Herald* Building, the United Charities Building, in New York, as well as in other buildings.

Replying to a question from Mr. Sprague, Mr. Leonard said that the location of his transformer would be determined by the style of the truck; at present it was laid out to be placed between the axles of the car, so that the axis of the motor generator would be parallel to the track.

THE FARMER IN ELECTRIC RAILROADING.

A RECENT issue of THE ELECTRICAL ENGINEER contained an article on the opportunity that the electric railway offered the farmer of handling his produce cheaply and of placing himself more directly and closely in communication with the country at large. It was urged that the highway without a track on it had ceased to be a highway in the full sense of the word. Mr. William Nelson Black, in the November issue of the *Engineering Magazine*, now presents the same idea with the supplement of some further arguments, many of them very strong. He goes moreover into a calculation of the cost and says: "An accurate estimate cannot of course be made here, because conditions differ so widely in different sections of the country; but as close a calculation as we can make in advance, founded on the cost of the electric railroads already in operation, warrants us in saying that probably 90 per cent. of the railways in the United States could be equipped with the necessary track, poles, and wires at a cost of $3,500 per mile. In a district 10 miles square—the surface that could be served from a single central power station—there would be, in the larger part of the Union, about 100 miles of railway. Then the total cost of track for a district 10 miles square would be $350,000. This represents a capitalization of only $5 to the acre, and an annual interest charge of only 30 cents per acre. With a central power station large enough to operate all the wagons or cars that would be called into use at one time in a district, the capitalization need not be more than $10 per acre. This would mean an annual interest charge of $60 for each hundred acres of land. It must be conceded that this does not seem like a very heavy tax when we consider the nature of the service rendered available, the great saving in the cost and maintenance of horses and wagons, the enormous economy of time, and the greatly enhanced value of improved farm lands. If the interest charge amounted to $100 per year, and the farmers were themselves chiefly the stockholders of the electric companies, it would still represent an economy."

MR. J. A. MCLURE, superintendent of construction of the Short Electric Railway Co., has resigned that position and joined the forces of the Siemens-Halske Co. of America, with headquarters at Chicago.

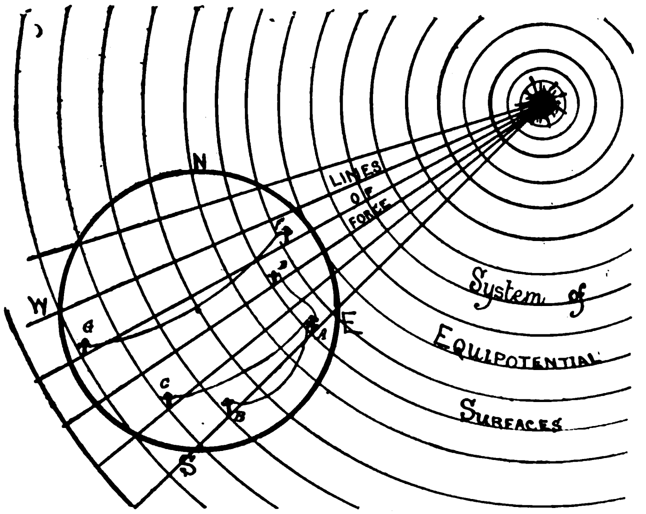
MISCELLANEOUS.

EARTH CURRENTS.[1]

BY WM. FINN.

THE author began by discussing magnetic or electric storms, their causes and effects, and the probable way in which these electrical disturbances, produced by solar convulsions, are transmitted in waves through the ether and imparted to what he termed the "electrical atmosphere" of the earth, inducing electrical waves, or earth currents. During the prevalence of these earth currents, he said, the earth's surface is divided into equipotential planes, between any adjacent two of which a difference of potential always exists. The greatest interruptions are invariably felt along lines of force running across these planes.

The accompanying diagram roughly illustrates the manner in which an electrical disturbance is propagated from the sun to the earth. The disturbing force gives rise to a series of electrical impulses which are transmitted in all directions through space in the form of spherical waves which develop upon the surface of the earth those lines of equal pressure or potential represented in the drawing as circles or portions thereof. The electric force like many other forces diminishes with the distance according to the law of inverse squares, but the value of the force at a given point on any one of the circles is the same as at all other points on the same circle because they are all equally distant from the centre of disturbance. Hence such a circle represents an equipotential surface along which the natural forces are inactive. All other surfaces, however, will necessarily have different values, and therefore an inequality of potential exists which tends to create an E. M. F. in any telegraph wire connecting the various circles. It is this difference of potential which drives the electricity through the wire.



The straight lines radiating from the sun represent the lines of electric force along which the earth currents are impelled with the greatest velocity, as it were. Telegraph circuits that run along these lines of force, such as A B and F G, are the ones *most* strongly affected. Circuits that cut the equipotential circles at other than a right angle, as A C, are not so seriously troubled, while those wires terminating on any part of an equipotential surface, as A D are absolutely free from interruption.

If we know the direction in which the circuits are entirely destitute of earth currents, we can deduce therefrom the line of maximum force, for that line is always at right angles to the system of equipotential surfaces.

These planes generally run about north and south in this country, and it is on that account that telegraph lines extending in this direction are found comparatively free from interference during abnormal earth current visitations, while those wires running across the equipotential planes, experience the maximum disturbing effects, which accounts for our easterly and westerly circuits being the greatest sufferers at such times.

The magnitude of the forces developed in the wires evidently bears some relation to the length of the circuit, as might be naturally supposed, and experience shows that the maximum potential difference exists as a rule between the terminal grounds of our longest wires. During the past term of storms for instance, the circuits between New York and Buffalo, which vary from 450 to 482 miles in length, exhibited the highest E. M. F's.; the value of which on several occasions exceeded 600 volts, and on Aug. 12 last, reached the unprecedented magnitude of 768 volts.

Twice or thrice during the recent storm period, there appeared to be a sudden shifting of the equipotential planes to an easterly and westerly direction, which is quite an unusual, as well as remarkable, circumstance, and one quite difficult to properly account for. At the times referred to, the wires north and south, which had previously experienced little or no interruption, became totally unworkable, whereas the easterly and westerly route appeared to be more or less clear of the earth currents. There were times also when a number of wires between the same points would be influenced in such a manner, that while one or two might be found perfectly workable the rest could not be operated at all. These curious anomalies together with other strange inconsistencies that were noted at the time, can only be explained on the supposition that some of the equipotential lines instead of forming portions of spherical surfaces, were more or less distorted by the action of other disturbing influences into highly irregular figures such as the spectrum of one magnet would show in the presence of other magnets. Irregular curves formed in this way and passing through the various points noted—*all being necessarily at the same potential*—would render possible the maintenance of regular communication between such points.

The author then devoted some time to the various theories concerning normal earth currents, and showed diagrams of readings taken upon a portion of the Atlantic cable in 1857 illustrating electrical tidal effects. The effect of local interferences upon the working of telegraph lines was then considered at length, and the paper closed with the statement that, although the phenomena of earth currents are but imperfectly understood, their effects are so universal and important that it requires no great stretch of imagination to conceive the possibility of an extended application of these currents to useful purposes at some future time.

---

[1] Abstract of a paper by read before the Brooklyn Institute of Arts and Science.

SOCIETY AND CLUB NOTES.

NEW YORK ELECTRICAL SOCIETY.

THE last meeting of this Society was held on November 10, at Columbia College. Mr. R. S. Dobbie delivered an interesting lecture on "The Electric Arc," with experimental demonstrations, an abstract of which will be found in another column. The interest shown in the Society's work is evinced by the rapid increase in its membership, over thirty new members having joined during the last month. The course of experimental lectures, which has been arranged, will be carried on throughout the winter. Full information and tickets of admission can be obtained from Mr. Geo. H. Guy, Secy., Room 812, 203 Broadway, New York.

"A HOUSE WARMING."

THE ELECTRICAL ENGINEER entertained its many friends on Wednesday afternoon, Oct. 26, in its handsome new offices in the *Mail and Express* Building, 203 Broadway, New York. An elaborate luncheon was served to the several hundred gentlemen present, who thoroughly enjoyed the hospitality of the popular staff of our esteemed contemporary, whose marked success in the field of electrical journalism is so pronounced and so deservedly earned.—*Street Railway Journal.*

CONSOLIDATION OF EICKEMEYER-FIELD INTERESTS.

A CERTIFICATE of consolidation of the Eickemeyer-Field Company, the Eickemeyer Dynamo Machine Company and the Yonkers Machine Company, under the name of the Eickemeyer-Field Manufacturing Company, has been filed with the New York Secretary of State. The company has a capital of $1,000,000, and will construct power and electric light plants and manufacture electric railroad equipments at Yonkers. The directors are Rudolf Eickemeyer, Henry Osterheld, Stephen D. Field, Norton P. Otis, and William D. Baldwin of Yonkers, and E. A. Nichols and Samuel Shethar of New York City.

A STEEL OBSERVATORY FOR NIAGARA.

BUFFALO capitalists propose to erect a steel observatory 250 feet in height at Niagara Falls. The plans and specifications call for a structure 70 feet at the base, 250 feet high, tapering to 18 feet at the top. The frame will be built of four main columns 15 inches square, around which the covering will be placed. A platform 88 feet in circumference will surround the top, furnishing room for 80 people to stand. Two elevators propelled by electric power will travel the vertical path leading to the top. They will have a capacity of 25 passengers each, and make the journey in half a minute. The entire structure will be brilliantly illuminated by electricity.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED NOVEMBER 1, 1892.

Alarms and Signals :—

District Alarm Box, C. W. McClellen, Chicago, 485,351. Filed Aug. 1, 1891.

Has for its object to prevent false alarms by sounding an alarm at the sending box simultaneously with the one at the main station.

Electric Signal, G. McIntosh, Stonington, Conn., 485,352. Filed March 10, 1892.

Has for its object to provide an auxiliary circuit of low amperage through the commutator operated by the motor which shall make and break the circuit for directly operating the signal.

Electric Bell, J. R. Hard, New York, N. Y., 485,379. Filed June 7, 1892. (See THE ELECTRICAL ENGINEER, Nov. 9).

Electric Danger Signal for Moving Trains, J. McCarty and A. G. Judkins, Trenton, Mich , 485,473. Filed Sept. 26, 1891.

Watchman's Electric Time Recorder, J. A. Tilden, Hyde Park, Mass., 485,591. Filed June 22, 1892.

Distribution :—

Electric Lighting System, W. H. MacKay, Roanoke, Va., 485,287. Filed June 13, 1892.

Employs lights placed in a branch of the main railway circuit and means whereby this branch circuit may be closed from a single point.

Electric Intermutator, H. G. O'Neill, Louisville, Ky., 485,425. Filed Feb. 9, 1892.

Provides automatic means for rapidly and intermittently distributing current to a number of points.

Dynamos and Motors:—

Dynamo, W. H. Elkins, Cambridge, Mass., 485,181. Filed Oct. 7, 1891.

Employs two sets of brushes at points of normally different potential, taking equal current at full load, and two sets of field-magnet coils, the one connected to one set of brushes, and to the work circuit, and the other between the brushes.

Dynamo Electric Machines, D. Pepper, Jr., Philadelphia, Pa , 485,220. Filed March 28, 1892.

Provides means for constructing field-magnet coils and armature rings in sections.

Regulation for Dynamo Electric Machines, E. Thomson, Lynn, Mass, 485,239. Filed April 6, 1888.

Employs means for taking current from a section only of the armature winding irrespective of the main current connections, a device responding to this current and controling mochanism for shifting the brushes of the machine.

Armature Core for Electric Motors and Generators, A. J. Lehman, New York, 485,284. Filed Jan. 30, 1891.

An armature core composed of magnetic gauze rolled upon itself and soaked in a solution of shellac or similar substance.

Galvanic and Thermo-Electric Batteries:—

Galvanic Battery, W. A. Crowdus, Memphis, Tenn., 485,319. Filed Dec. 18, 1891.

Claim 1 follows :

In a galvanic battery, a battery case provided with metal rods extending through it from top to bottom and connected at their bottom ends to the respective electros of the battery.

Heating:—

Electrical Heater, H. G. O'Neill, Louisville, Ky., 485,424. Filed Feb. 2, 1892.

Employs a steatite heater body and a non-conducting cement for attaching the wires to the heater body.

Lamps and Appurtenances :

Electric Arc Lamp, J. A. Mosher, Chicago, Ill., 485,293. Filed Jan. 2, 1892.

Employs a carbon rod provided with a fiber plug having a groove and a contact adapted to move in electrical contact with the rod and engage the groove.

Electric Arc Lamp, E. R. Knowles, Stonington, Conn., 485,327. Filed Nov. 24, 1891.

Employs a vertically-moving perforated ribbon, supported to the frame of the lamp, as a means for raising, supporting and feeding the upper carbon.

Electric Arc Lamp, H. Japy, Beaucourt, and O. Helmer, Paris, France, 485,347. Filed Mar. 22, 1892.

Relates to the construction of differential arc lamps designed to operate in circuit with either a continuous or an alternating current generator.

Incandescent Electric Lamp, E. Pollard, Cambridge, Mass., 485,478. Filed Mar. 2, 1892.

Employs two bands or deposits of silver upon the filament-supporting tube extending through the seal and forming an electrical connection between the filament and conducting wires.

Electric Arc Lamps, E. A. Edwards, Cincinnati, Ohio, 485,537. Filed Nov. 25, 1891.

Employs a positive refractory stop against which the positive electrode rests, the negative electrode being fed toward the positive in a direction substantially at right angles to the length of the latter.

Socket for Incandescent Electric Lamps, J. S. Potter, Newton, and D. J. Cartwright, Boston, Mass., 485,587. Filed Oct. 6, 1890.

Consists of a block of porcelain provided with recesses at opposite ends separated by a partition, and contacts connected with the conducting wires and mechanically attached to the partition in the socket.

Miscellaneous:—

Automatic Governing Device for Electric Pumps, F. A. Pocock, Lynn, Mass., 485,221. Filed Mar. 20, 1891.

Employs a float by means of which the level of the water in the tank controls the current.

Device for Treating Patients by Electricity, E. M. Thomas, Little Rock, Ark., 485,238. Filed Jan. 11, 1892.

Apparatus for Winding Wire, F. B. Chase, Chicago, Ill., 485,256, Filed Jan. 4, 1892.

Self-Induction Device, W. Stanley, Jr., Pittsfield, Mass., 485,336. Filed April 19, 1891.

Employs a laminated magnetic core, a continnous magnetic coil, whose sections are wound through perforations in said core, a series of contact plates to which the sections are attached, a contact lever for including more or less of the sections, and a circuit for alternating currents.

Method of and Apparatus for Electro Deposition of Metals, C. R. Fletcher, Boston, Mass., 485,348. Filed Oct. 5, 1891.

Electrical Door Trip for Engine Houses, A. Bosch, Newark, N. J., 485,367. Filed March 14. 1892.

Alloy, H. G. O'Neill, Louisville, Ky., 485,423. Filed Jan. 30, 1892.

An anti-fusion alloy of great electrical resistance consisting of stated proportions of tin, silicon, nickel, and zinc.

Jail or Vault Construction, D. K. Osbourne, St. Paul, Minn., 485,506. Filed Sept 8, 1891.

Employs metallic pipes with wires therein adapted to sound an alarm when the pipes are in any way disturbed.

Construction of Jails, D. K. Osbourne, St. Paul, Minn., 485,559. Filed Jan. 4, 1892.

Similar in its object to 485,506.

Coin Controlled Stereoscope, J. Ringen, St. Louis, Mo., 485,567. Filed Feb. 12, 1892.

Railways and Appliances :—

Underground Electric Trolley System, R. B. Ayres, New York, N. Y., 485,252. Filed March 23, 1892.

Has for its object to provide means for electrically operating all kinds of signals arranged in a continuous line as well as all kinds of tripping mechanisms to operate such signals at certain distances apart.

Underground Electric Conduit and Trolley Bar for Electric Railways, J. S. Moss, Martinsburg, W. Va., 485,555. Filed April 16, 1892.

Has for its object to provide a conduit wherein the trolley bar is constantly insulated from the edges of the slot and the latter is effectually closed to exclude water, etc.

Switches and Cut-Outs :—

Circuit Switch, M. E. Sullivan and J. Doss, Denver, Col., 485,387. Filed April 2, 1892.

Has for its object the division of the main circuit into independent sections.

Electric Switch, J. C. O'Neill, Cleveland, Ohio, 485,558. Filed Oct. 14, 1891.

Telegraph :—

An arc circuit switch for house service.

Combined Telegraphy and Telephony, W. W. Jacques, Newton, Mass., 485,279. Filed April 8, 1892.

Claim 1 follows.

The combination of an electrostatic inductive resistance and an electromagnetic inductive resistance in an electric circuit.

Electromagnetic Telegraph Apparatus, A. G. Safford, Washington, D. C., 485,334. Filed Mar. 16, 1892.

Has for its object reduction of the resistance of the main circuit and increased sensitiveness in the receiving instrument, as well as the ready adjustment to varying pressure of the circuit.

Telephones and Apparatus :—

Telephone, A. C. White, Boston, Mass., 485,311. Filed Mar. 24, 1892.

Provides means for overcoming the tendency to pack of the finely divided conducting material and undue heating of the essential parts. (See this issue THE ELECTRICAL ENGINEER.)

LEGAL NOTES.

EDISON ELECTRIC LIGHT COMPANY AND EDISON GENERAL ELECTRIC CO. vs. SAWYER-MAN ELECTRIC CO.

THE hearing in the suit of the Edison companies for preliminary injunction against the Sawyer-Man Co., postponed from November 4 to November 11, has again been laid over until Friday, November 18.

LETTERS TO THE EDITOR.

ANSWER TO THE QUESTION ON "SPARK LENGTH."

IN answer to the question on "spark length" submitted in your issue of November 2, I would submit the following:

The potential is approximately 2,000 volts. Between 1,500 volts and 25,000 volts the sparking distance between parallel metal surfaces in air can be approximately expressed by the formula:

$$d = 22\,V + \tfrac{1}{2}\,V^2 - 14,$$

d being the distance in mils or thousandths of an inch, and V, the potential, in thousands of volts.

CHAS. P. STEINMETZ.

YONKERS, N. Y.

THE SPRAGUE-PRATT ELEVATOR.

I HAVE just read the interesting description of the Sprague-Pratt electric elevator in your issue of November 2. It is, no doubt, the intention of the writers, that all who read this article shall get the impression that this elevator overcomes all difficulties heretofore known in the art, or which possibly can arise. Certainly there is mechanism enough about the machine to provide for almost any contingency, and yet in the attempt to overcome all that "friction" on the 'travelling nut," the projectors have overlooked what would happen in case the "vicious boy" attempted to start the elevator with an overloaded car. It looks to me very much as if the controlling motor would gradually, but surely, cut all the resistance out of the armature circuit, and then, the armature remaining stationary, either the fuses or the armature would be destroyed. In either event, the annoyance of waiting for repairs is encountered. I wonder if this condition was one of those imposed on the elevator in West Twenty-third street. If so, it would be interesting to know the result.

WM. A. ROSENBAUM.

NEW YORK, Nov. 4, 1892.

PERSONAL.

MR. G. G. WARD, the vice-president of the Commercial Cable Company, after an absence of about six months, returned from Europe not long since. Mr. and Mrs. Ward were compelled by circumstances to spend the twenty-fifth anniversary of their marriage on the S. S. "City of Paris" in mid-Atlantic, but they were not forgotten by their friends and admirers in the Commercial Cable Company, who, a few days after their return home, surprised them overwhelmingly by the presentation of a silver dessert service. It is an exceedingly handsome set, made and engraved by Tiffany.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

Advertising is a constant want and should be a constant study.

TEST OF THE STROWGER AUTOMATIC TELEPHONE EXCHANGE SYSTEM.

A LARGE party of gentlemen comprising a number of Chicago's prominent citizens, electrical experts and newspaper representatives visited La Porte, Ind., on Thursday, Nov. 3, to inspect the new automatic telephone exchange, the invention of Mr. A. B. Strowger, which has just been installed there, being the first system demonstrating the practical application of an automatic exchange, and which was formally opened on the occasion, having been completed but a few days. A special train for La Porte on the Lake Shore and Michigan Southern was provided which left the city at 10.30 in the morning and reached La Porte about noon. Lunch and refreshments were served on the train and the commissariat in the hands of Mr. Jos. Harris, Mr. M. A. Meyer and Major C. J. Wickersham was handled in a masterly manner and is something to be remembered by the guests for a long time to come. The party reached La Porte about 1 o'clock where the town's cornet band had turned out to receive them, and preceded the visitors to the offices of the Strowger Company. Mr. H. H. Craig, New York agent for the company, received the guests and introduced Mayor Scott, of La Porte, who extended the freedom of the city and made a short and cordial address of welcome. Mr. A. B. Strowger, the inventor of the system, was introduced and made a short speech touching on the pleasure the present demonstration gave him as the fulfilment of his hopes and related a few of his experiences while working out the system and reviewed the history of the telephone and the tribulations of the telephone girl whom his automatic apparatus is designed to relieve and retire. Mr. H. M. Underwood, who has charge of the construction and Mr. A. E. Keith, the electrician of the company, were on hand to explain the practical working and details of the system and for the next couple of hours the guests amused themselves by calling up every one in town who had telephones and asking questions about how they liked the new system, and so forth; replies being invariably favorable. The following were among those present: H. G. Flederman, S. S. Vandervort, Major Charles J. Wickersham, Prof. John P. Barrett, William Hood, General William Sooy Smith, A. D. Tingley, James W. Scott, F. S. Perry, Chief Swenie S. Engel, W. F. Collins, C. Gentile, Albert Fishell, C. A. Barre, J. A. Loebe, H. W. Perce, John M. Smyth, C. F. Dunderdale, M. B. Heller, M. M. Cohn, Phillip Howarth, M. A. Meyer, S. H. Mallory, G. R. Stewart, William Corroll, Fred. Le Land, B. B. Farwell, Dr. S. Cole, W. H. Rattenburg, Eli D. Felsenthal, E. E. Yaxle, Oscar Stein, J. Harris, A. B. Strowger and J. F. Mehren.

J. W. PARKER & CO.

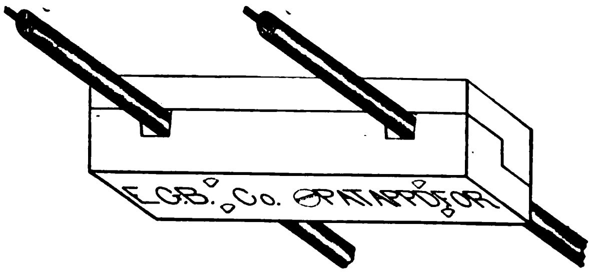
THE above firm, of 38 South Fourth street, Philadelphia, report the following sales during September and to date: North Hudson Elevated Railroad, Hoboken, N. J., two 250 h. p. Standard improved Ball engines, of Erie; Suburban Electric Light Company, Scranton, Pa., one 200 h. p. Standard improved Ball engine; Elkton Electric Light Company, Elkton, Md., one 80 h. p. improved Ball engine and 90 h. p. boiler, and entire plant construction; Milton, Pa., Electric Light Company, one 100 h. p. improved Ball engine; Bloomsberg, Pa., Electric Light Company, one 100 h. p. improved Ball engine; Pottstown Light, Heat and Power Company, Pottstown, Pa., one 250 h. p. cross-compound Ball engine; Penna. General Electric Company, Philadelphia, Pa., for shipment to Malten, West Va., one 80 h. p. engine and 90 h. p. boiler and complete plant, erection, the whole latest improved manufactures of the Ball Engine Company, of Erie, Pa.; the Wm. A. Rogers Company, Philadelphia, Pa., one 50 h. p. Standard improved Ball engine. This company reports inquiries to be very numerous, and the best business they have ever had. Besides the reports given above, they have several good contracts for their high grade special boiler; they are building two of these, each 150 h. p., for the Bethlehem, Pa., Electric Light Company; a large stack for same company and construction work for their new improvement.

THE BERNARD ADJUSTABLE CHINA CLEAT.

THE accompanying illustration shows a new form of china cleat especially designed to meet the requirements of insurance experts, who have recently prohibited the use of wood for this purpose. It has had the advantage of a practical test and is found to be strong and easy to put up.

As will be seen, the top and bottom are exactly alike and are interchangeable. The cross-section is designed for strength, and, as it is held in place by means of only one screw and the four fixed lugs, perfect alignment is secured. It is made of superior imported clay, thoroughly vitrified, and is furnished both glazed and unglazed.

This device is manufactured by the E. G. Bernard Company, of 7 First street, Troy, N. Y., and is supplied to the trade by the Western Electric Co., the E. S. Greely & Co., and Alexander, Barney & Chapin, of this city. The makers report that although orders have not yet been solicited to any extent, over 100,000 cleats have already been sold.



BERNARD ADJUSTABLE CHINA CLEAT.

PURITY OIL FILTERS.

THE PURITY OIL FILTER MANUFACTURING CO. have announced that Messrs. W. R. Fleming & Co., 203 Broadway, will henceforth represent them in this city, and, by way of showing what is going on at their works, report the following sales, some of which are second orders: Ferries and Cliff House Street Railway Co., San Francisco, Cal., one No. 2 Ideal oil refiner; Mineral Point, Wis., Zinc Co. one No. 1 Eureka; Tennessee Manufacturing Co., Nashville, Tenn., one No. 4 Ideal oil refiner, second order; Plattsburg, N. Y., Light, Heat and Power Co. one No. 2 Ideal; Vacuum Oil Co., Rochester, N. Y., Royal Electric Light, Heat and Power Co. one No. 2, Purity Filter, Front Royal, Va.; Judson Manufacturing Co., Oakland, Cal., one No. 2 Ideal; Detroit, Mich., Citizens Street Railway Co. one No.1 Ideal; Rockaway, N. J., Manufacturing Co. one No. 1 Ideal refiner; Carnegie Steel Co. Ltd. for Homestead Steel Works, second order, one No. 2 Ideal refiner; New Castle, Pa., Wire Nail Co., second order, one No. 4 Ideal refiner; Indiana, Pa., Electric Co. one No. 2 Ideal; Frederick, Md., Electric Light and Power Co. one No. 1 Ideal; People's Light and Power Co., Silver Creek, N. Y., one No. 1 Purity filter; Pittsburg Plate Glass Co., fourth order, one No. 3 Purity filter. This company is also in receipt of the following gratifying letter:

MACON, GA., Nov. 2, 1892.

PURITY OIL FILTER MANUFACTURING Co. Pittsburgh, Pa.

Gentlemen:—Enclosed pleased find cheque for $50, to pay for No. 2 Ideal refiner purchased from you some time ago. We find your oil refiner all you represented and more too than you claimed for it. We were determined to be satisfied as to its merit before paying for it as we have been humbugged several times before. When we put the refiner to work we were using 150 gallons of oil per month. Now with the aid of the refiner we use only 50, which saves the price of the refiner in one month.

Yours respectfully,
Metropolitan Street Railway Co.
S. A. MITCHELL, general manager.

MR. J. STANFORD BROWN, consulting electrical engineer, of Camden, N. J., may be addressed to advantage by those having arc lamps suited to run on 500-volt railway circuits, and by persons manufacturing electric heaters.

THE HARD ANNUNCIATOR DROP.

Last week we illustrated and described the new bell and dry battery of Mr. J. Randolph Hard, of 2 and 4 Howard street, this city.

Another very neat device just brought out by Mr. Hard is an annunciator drop shown in perspective in the engraving, Fig. 1. The construction of this drop will be readily understood by referring to the diagram, Fig. 2, which shows a top view of the drop and Fig. 3 which shows it in position in the annunciator. As will be seen, the armature is carried by a spring, which has a collar soldered to the spindle upon which it turns. When the drop is set for action, the armature is held in position opposite to the core of the magnet by a knife-edge which engages a slot in the top of the armature. When the button is pushed current is sent through the magnet coil, the armature is attracted, clears the knife-edge and by its own weight drops into the indicating position, shown in the upper magnet, No. 1, Fig. 3.

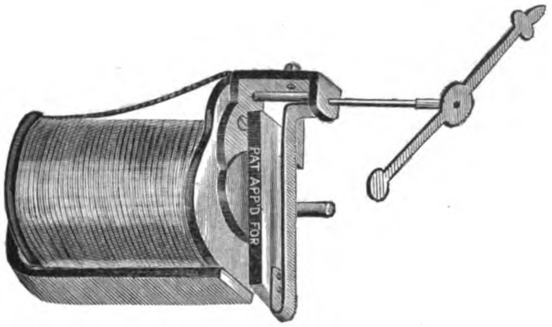


Fig. 1.—Hard Annunciator Drop.

The construction here adopted, it will be noted, is exceedingly simple. It cannot get out of adjustment, as the whole drop device is attached to the magnet, and is independent of the warping of the woodwork. The arrangement is such, also, that the most violent jarring will not release the drop, and thus give false signals. The tests which we have witnessed are sufficiently convincing of the character of the drop in this respect. As the armature is directly suspended, it requires but a minimum amount of battery to release it from the knife-edge, the friction amounting to almost nil, owing to the entire absence of pivots.

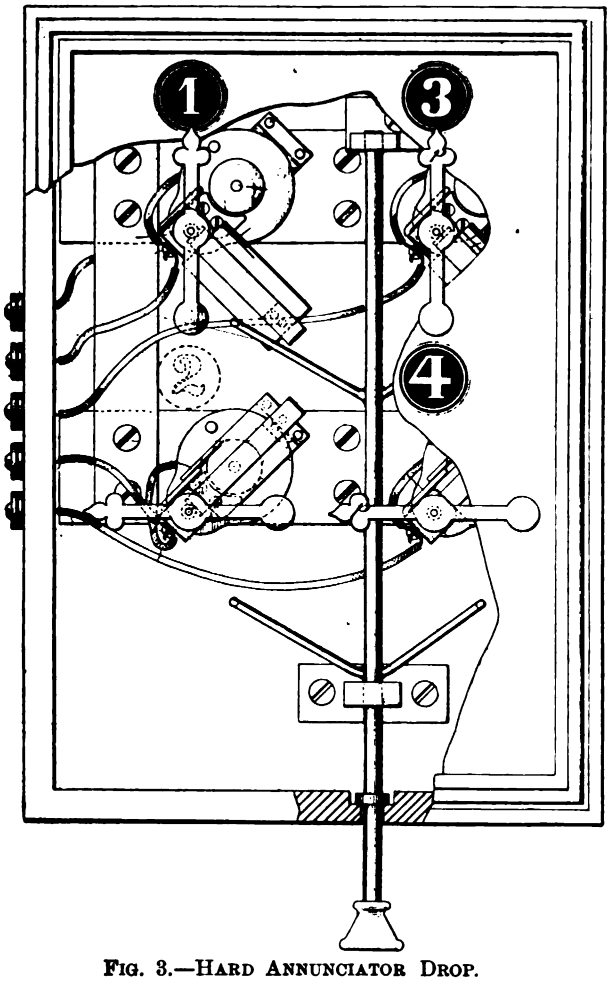

Fig. 3.—Hard Annunciator Drop.

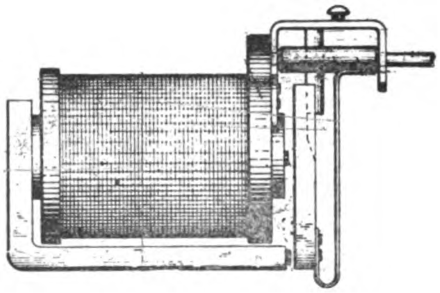

Fig. 2.—Hard Annunciator Drop.

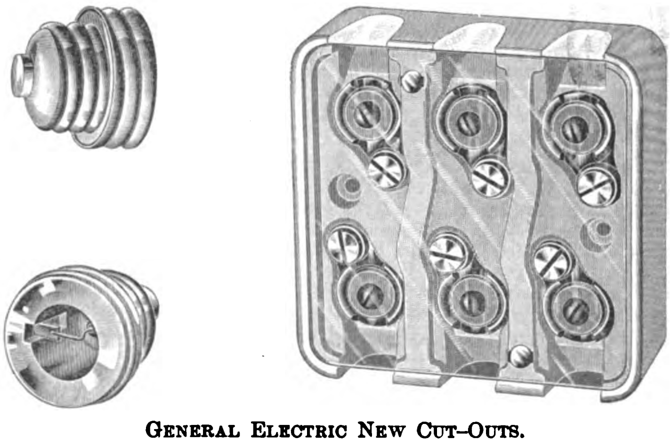
Our engraving Fig. 3, shows an annunciator, with four such drops arranged in working order; the drop No. 2 being in position before the pushing of the button, and drop No. 1 after.

GENERAL ELECTRIC CO.'S NEW STYLE CUT-OUTS.

Improvement in the manufacture of the smaller electrical appliances keeps pace with that of the larger and more important devices, each moving toward perfection. We here show some improved pieces of wiring apparatus, which the General Electric Co. has just brought out. The old style porcelain plug and link cut-outs have disappeared and the new ones here shown take their places as substitutes of greater efficiency. They are made of hard, white, thoroughly vitrified porcelain, impervious to moisture, and impassable to the electric current. the metal parts possessing all the qualities necessary to render them electrically efficient. The plug cut-outs are designed to protect a circuit having a maximum current of 30 amperes at 125 volts. The fuse is carried in a small glass plug, cased and covered with brass, which is screwed into a brass screw socket in the body of the cut-out. Should the fuse blow, the defective plug can be instantaneously replaced, without tools of any kind. In the link cut-outs, the fuse is a safety link with copper terminals. The binding screws and wire terminals are set well below the surface of the cut-out, and are protected by suitable sheet-mica covers. The porcelain of which these cut-outs are manufactured, is itself made by the General Electric Co. at its own porcelain factory at Schenectady, established in order that the quality of this important material should be of the highest possible standard of excellence.



General Electric New Cut-Outs.

Mr. Harry S. Smith, who for several years past has been connected with Walker & Kepler, Philadelphia, has severed his connection with that firm, and associated himself with some well-known electrical men who will be known hereafter as the Harry S. Smith Co., Ltd., and located at 607 Chestnut street. They will handle the Eddy apparatus in isolated plants. They are also agents for the Eddy dynamos, Safety Insulated Wire and Cable Co. and Packard incandescent lamps, and will keep a stock of general supplies for all systems of electric lighting.

WESTERN NOTES.

The Premier Steel Company, Indianapolis, Ind., have issued an announcement of their elevator department of which Mr. Clinton B. Osgood is general sales agent, with offices at No. 319-320 Manhattan Building, Chicago. The Premier Steel Company have lately added to their immense works at Indianapolis, an elevator department, and are now fully prepared to manufacture electric, hydraulic and steam elevators for passenger and freight service. Before entering the business, electrical and mechanical engineers, fully alive to the requirements of their large and increasing business, were engaged, and have placed elevators in fine buildings near their place of manufacture so as to be constantly under their supervision, that any faults developing might be remedied before soliciting business. The Premier Steel Company have paid particular attention to the developing of an electric elevator that shall be perfectly smooth running, safe, high-speed, using a minimum amount of current and be free from the annoyances of repairs. One of these machines has now been running for the past eight months and has never been shut down for an hour. It is said to be giving the best satisfaction to the users, and has been highly praised by those who have seen it in operation and has not had $1.00 of repairs since it started in service. Now that every point of its efficiency and economy has been proven to the Premier Steel Company they are prepared to contract and erect their machines wherever required. Mr. Clinton B. Osgood, their general sales agent, was for some years connected with one of the largest and most prominent elevator companies in the United States and for the past five years has been prominently connected with the Sprague Electric Railway and Motor Company and the Westinghouse Electric and Manufacturing Company. He will be pleased to give detailed information regarding not only electric, but hydraulic and steam elevators.

James P. Warren, No. 51–53 North Jefferson street, Chicago, is doing a large business with electric light and railway plants with his "Acme" exhaust head. This head is especially designed for electric plants and high speed engines, so as to economize exhaust steam. Mr. Warren guarantees it to stop all water and grease that is emitted from the exhaust pipe and by condensing it, the hot water runs down a conductor and up a passage into the bottom of the head and from thence through a detachable drip pipe into a tank or cistern from which it can be taken for boiler feed, washing or other purposes. By the use of this device, roofs, walls, windows and surrounding buildings are protected from the water and grease that escapes from an exhaust pipe. Among other advantages of the head are that it frees itself from grease and sediments while in use. and is a great benefit to all non-condensing engines. They are made of heavy galvanized iron and guaranteed to last for several years. Mr. Warren has just sold the Brush Electric Light Co., of Cincinnati, a 14-inch exhaust head, which is stated to be working in first-rate shape. This head goes on a 500 h. p. engine.

The Universal Electric Co., 739 Cedar avenue, Cleveland, Ohio, has been recently organized with Mr. N. S. Possons, president and manager, universally known among electrical people all over the country from his long association with the Brush Electric Co. Mr. Geo. R. Lean is vice president and superintendent, and Mr. W. J. Possons, formerly of the Brush Electric Co., secretary and treasurer. The new company are taking up a highly novel class of business, namely, that of repairing lamps, rendering them, it is stated, fully equal to new lamps. They replace broken and burned out filaments, remove the soot and smoke which adheres to the inside of the bulb, finishing up the lamps so that they are exactly as new. This process makes a material saving to the users, as the cost of repairing is much less than new lamps. The company also report that they are making segments and tempering same, casting them from copper for commutators, as well as for all electrical work where great strength and good conductivity are required.

The Columbia Mfg. and Supply Co., 340-342 Dearborn St., Chicago, of which Mr. D. F. Coykendall is president, Mr. Thomas Hull, vice-president; Mr. John T. Todd, secretary and treasurer, and Mr. C. R. Baum, superintendent, are doing a light manufacturing business in electrical instruments, tools, gears, etc. They also represent the Standard Thermometer Co., of Peabody, Mass. Mr. Todd expects to place on the market, shortly, several valuable electrical devices of his own invention.

The Bain Electric Mfg. Co., manufacturers of electric light, power and electric mining machinery, 47 and 49 S. Jefferson street, Chicago, are constructing two large mining locomotives, and also have under way an electric under-cutting coal mining machine. Their new arc lamp for series arc and direct incandescent circuits are proving very satisfactory.

The Chicago Incandescent Light Co. report business as very good and are turning out a large stock of their incandescent lamps. Mr. Thos. Pray, Jr., is general manager and electrician, and has charge of the factory and personally supervises the output. Mr. Stephen Lissenden is treasurer, and attends to the business of the concern.

Mr. Carl K. MacFadden, electrical engineer at present in charge of all electric plants on the Chicago & N. W. Railway Company's system, has resigned his position and will join forces with Taylor, Goodhue & Ames, 827 Monadnock Building, Chicago. Mr. MacFadden is a young man of much more than usual ability and sound to the core on questions pertaining to electrical engineering.

Mr. Frank R. Ford is now settled down in Chicago as manager for the Short Electric Railway Co. here, with a fine suite of offices in the Monadnock Building. Mr. Ford is a very energetic gentleman, well versed in street railway work, and will, undoubtedly, prove very successful both for himself and his company in this section.

The Standard Battery Co., 324 Dearborn street, Chicago, are filling a number of orders for their iron gravity batteries for railroad telegraph work. Mr. A. P. Willoughby, the inventor of the iron electrode for gravity batteries, has also about perfected a new battery for light power, such as sewing machine work.

Mr. B. E. Davis, representing Pass & Seymour, the well-known manufacturers of electrical specialties and the celebrated Syracuse china, of Syracuse, New York, was among the recent Chicago visitors. Mr. Davis, while here, found time to drop in at the Western office of **The Electrical Engineer**.

Taylor, Goodhue & Ames are receiving a large number of orders for the Burton Electric Car Heaters. They have recently furnished twenty-four sets to three large Western roads. This speaks volumes for the heaters as all these are repeat orders from roads who have used the heater during last fall.

The Acme Oil Filter.—Taylor, Goodhue & Ames have been appointed general selling agents for this filter and have certain exclusive territory. The filter is a good one and possesses the advantage of a steam chamber which can be used to good advantage in cold weather or with extra thick oil.

Mr. Wells Goodhue of the firm of Taylor, Goodhue & Ames is, it is reported, hard at work upon an electrical poem expected to appear during the festal days of Christmas. Rumor has it that it incidentally touches on the fate of the yellow dog who fell asleep on a Burton heater.

Mr. T. A. Pamperin, general manager of the Electric Mfg. Co., Oconto, Wis., whose office here is at No. 239 La Salle street (Wm. Hood & Co., managers), spent several days in Chicago, last week. Mr. Pamperin received the usual hearty welcome from his many friends.

The Great Western Electric Co. 207 South Canal street, Chicago, are enjoying an excellent run of business in all lines of supplies that they handle. Sun arc lamps are in good demand as also are Howard incandescents and many of their other specialties.

Mr. C. B. Fairchild, the editor of the *Street Railway Journal*, New York, spent several days in Chicago during the past week. Mr. Fairchild is making quite a Western trip, and will, no doubt, find many things to interest him in street railway matters.

Mr. H. Jenkins, who is well known among electrical people here, has accepted a position with Fraser & Chalmers, the large manufacturers of mining machinery, steam engines and boilers, of Chicago, in their city sales department.

Mr. Wm. J. Chalmers, vice-president and treasurer of Fraser & Chalmers, returned some little while ago from Europe, after a two or three months' trip there. The company has extensive works in England.

CANADIAN NOTES.

The Canadian Electric Light Co.—The Dominion Government has under consideration for approval the plans of this company for developing the water power of the river at the side of the Island of Montreal opposite to that on which the city is situated. It is proposed to dam the river at Sault-au-Recollet, which would obliterate the rapids at this place and it is estimated yield from 15,000 to 20,000 h. p. for conversion into electricity and transmission to Montreal, seven or eight miles distant.

The Canadian General Electric Co.—The following officers have been appointed: President, W. R. Brock; first vice-president, H. P. Dwight; second vice-president and general manager, Frederic Nicholls; assistant general manager, M. D. Barr; comptroller, Walter S. Andrews; chief engineer, W. M. Rutherford; assistant engineer, H. T. Hartman; purchasing agent, Geo. W. Watts; superintendent Peterboro factory, Wm. S. Andrews; superintendent Hamilton factory, C. S. Stilwell.

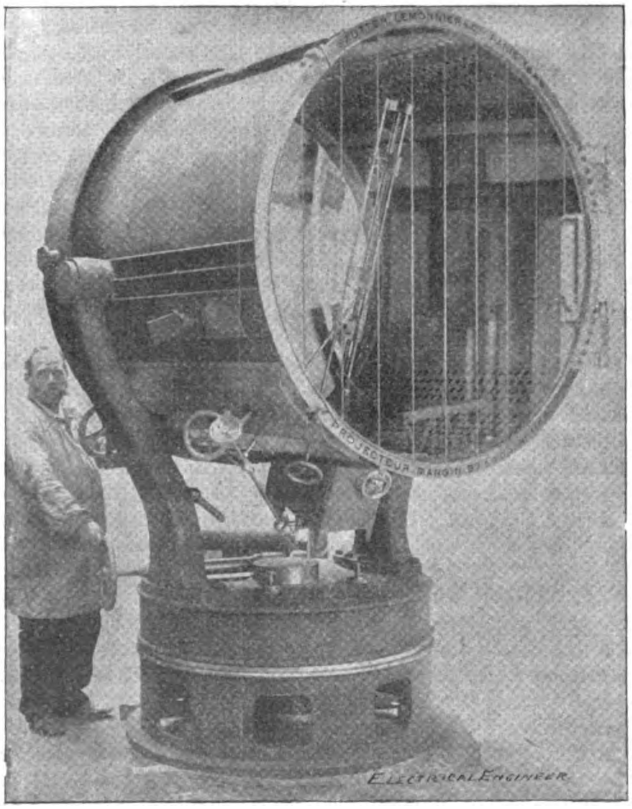
☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.

THE
Electrical Engineer.

Vol. XIV. NOVEMBER 23, 1892. No. 238.

THE LARGEST ELECTRICAL PROJECTOR IN THE WORLD.

THE interesting experiments made towards the end of the present summer with an electrical projector at the summit of Mt. Washington, which were fully described in our issue of September 28, by Mr. A. C. Shaw, have attracted attention not only in this country, but abroad. Among others we have received a communication from Messrs. Sautter, Harlé & Co., of Paris, the well-known French electrical constructors. In order to prevent the impression from getting around that the Mt. Washington projector is the most powerful one in the world, they draw attention to the fact that there exist in France, England and Russia, as well as in other countries, projectors of larger diameter, serving as coast defences. Whereas the Mt. Washington projector has a reflector of 30 inches, those in use abroad have reflectors 36 and 40 inches in diameter, and even this is by no means the limit.



The Largest Electrical Projector in the World.

The most powerful projector in the world was that constructed for, and exhibited at the Paris Exposition in 1889 by, Messrs. Sautter, Harlé & Co. This apparatus of which we give a reproduction from a photograph kindly furnished us by the above firm, has a reflecting Mangin lens of the same type as that of the Mt. Washington projector, but of no less a diameter than 60 inches. It was immediately after its construction acquired by the French Navy Department.

The Mangin reflector throws the rays absolutely parallel, which is demonstrated by experience with an arc lamp, taking a current of 200 amperes. This lamp can be operated either automatically or by being manipulated from the outside by means of hand wheels and rods.

The carbons employed have a diameter of $1\frac{9}{16}$ inch for the positive, and $1\frac{3}{16}$ inch for the negative. This 60 inch Mangin projector provided with a tilted lamp taking 200 amperes of current has, it is claimed, a luminosity of 267 million candles. The luminosity of the sun at the zenith being 53,500 candles, it follows that an object placed at a distance of 230 feet in the path of the projected rays, would be lighted as clearly as if exposed to the rays of the sun at noon in summer.

INCREASED COMMERCIAL EFFICIENCY AND HIGHER ECONOMY IN CENTRAL STATIONS—II.

BY

J. H. Vail

HIGH ECONOMY ENGINES.

THERE can be no doubt but that the central stations constructed in the United States for the next few years to come will require engines of highest economy as well as of larger powers than those heretofore employed. We must anticipate stations of larger capacity, in which, I believe, the units will range from 500 h. p. upward, rather than of smaller capacities.

In this connection, it must not be forgotten that the successful status of central station business of the present day has been achieved by the almost exclusive use of the simple high speed engine belted to dynamos running at high velocity. Instances are on record where in the same town, under same conditions, it has been proved that net profit could not be obtained with a slow speed engine and intermediate shafting, and where a high speed engine added to the same plant has been the turning point toward financial success. Therefore, whatever changes we may make in the future, we must not forget to give due credit to that type of engine which has been one of the corner stones of success in electric light stations. This is not intended in any manner to reflect on or question the economy and value of the slow speed engine in electric power stations, as the writer has in numerous instances endorsed the use of the same, and will continue to do so when the nature of load and specific conditions of operation will insure higher economy as the result.

In no instance should the system of duplicate generating units be abandoned. We must not fail to keep in mind the fact that where large generating units are applied, the disabling of one means the stopping of a large percentage of the station capacity. It is most desirable to build up the station capacity with several generating units, so that in the event of a breakdown only a small fractional part of the total capacity will be unserviceable. Absolute reliability is an essential element of success in electric lighting.

Engines for duty in electric power stations require to be exceptionally well proportioned and extremely heavy in all parts. They must be capable of withstanding, without damage, the instantaneous adding or cutting off of the entire load. They must also be constructed with a view of prolonged continuous running at full load. In fact, the service required is more stringent than that on ocean steamers or with railroad locomotives.

The importance of exact duplication of parts and interchangeability of those parts most subject to wear or breakage, must not be lost sight of. In large units, the changing of an armature on a shaft, or the dismantling of an engine to lift a large shaft, may be a work of many hours at best; if new parts are not found to fit, this may be extended to a work of days. A steamship engineer who has taken a liking to electric power station service recently remarked that "he had sailed on many a ship that could lay by and hoist canvas for repairs and would soon get to port, but the central station ship must always keep under way and never reach port."

The greater coal economy to be obtained by using compound or triple expansion engines is constantly presented in ways more or less attractive, and in many instances to sell an engine or cater to a popular idea, without due regard as to whether such a type will really be economical in a specific central station, when all the points of local conditions, required duty, first cost and future operating expenses are duly considered. It must be perfectly evident that we do not want to apply a compound engine where the conditions are such that owing to variable or intermittent load, the engine falls off in economy so that the steam it requires will be equal to, or average more, in pounds of water per horse power hour than the simple engine of less cost; but it is evident that the compound engine may be used to advantage where its application will reduce the average fuel and water consumption sufficiently below that of the simple engine. A recent report says that the results of a long series of tests made on several railroads, to prove the average economy of the compound over the simple locomotive, sum up into a final saving of 16.9 per cent. of coal and 14.1 per cent. of water. We may therefore safely anticipate considerable saving in fuel with compound non-condensing engines, while we may expect better results under constant heavy loads and with condensation.

One of the main questions after all, is the amount of saving in fuel which can be effected by the use of improved apparatus, and another, whether the saving in fuel will be materially greater than the interest on the increased cost plus the additional repairs on the more complicated engine. We must estimate an annual charge of interest on the increased cost of apparatus, this to be deducted from the net value of coal and water saved. It is therefore evident that the investment may only be warranted where coal is dear and may not be economical where fuel is cheap.

To obtain economical results in the daily operation of central stations having an aggregate of from 1,000 to 4,000 h. p. capacity, I believe that, as a rule, the triple expansion engine should not be operated with less than three-quarters its normal load. If the minimum load of the station should be such as to reach below this proportion of load on engine, I would suggest that the load be then taken up either by the ordinary high speed engine and belted dynamos, or by a smaller size of compound condensing engine either driving belted dynamos, or having direct driven multipolar dynamos. It will be understood that in large stations the minimum load will probably be sufficient to be carried on a triple expansion generator of 300 to 500 h. p. capacity.

The improved station of medium capacity should therefore be equipped with two or more simple high pressure or with compound condensing engines for service during hours of small load, and with two or more triple expansion condensing engines and direct driven dynamos for heavy load service. We may also anticipate in very large stations the future application in exceptional instances, of quadruple expansion engines.

Another important point in this combination of engines as recommended must be perceived, namely, that to run a simple engine during the hours of light load, engineers of less skill will be required than during the hours of heavy load, when the larger and more complicated types of engines are in service; on this latter watch more experienced men will be necessary. Should a station be arranged with triple expansion engines for high steam pressure, the simple engine must be specially constructed so as to operate at the high pressure, or, if an ordinary engine, a reducing valve should be interposed or lower boiler pressure carried.

In deciding upon the type and size of engine, great care must be observed as to conditions to be fulfilled. As before stated, we should be sure to more than compensate by extra profits for the additional quantity of machinery that must be maintained in motion. In this connection, engine friction is an important source of waste. The resistance of the engine due to internal friction of parts and the effort required for its movement at full speed, will vary according to its size, type, condition, etc. Engine friction can be assumed as nearly constant at all loads; therefore, the net results under variation in load are of great importance. The indicated work, less the friction of the engine, constitutes the net useful work, and for our purpose the net electric horse power delivered from the brushes of the dynamo is the important result upon which we base our estimate of commercial value.

While on this subject of engine friction, it will be readily perceived that, taking a compound engine under conditions of small load, it will at such time not do sufficient work to make full use of steam in the second cylinder, and it becomes possible that the friction due to moving the parts connected with the low pressure piston (as well as cylinder condensation, etc.) for many hours of small load, may more than compensate and overcome the economy gained by using the engine at its best economy for the few hours of heavy load. The same statement applies with greater force to the triple expansion engine, as in this type there is an additional cylinder with the moving parts required, practically a third engine, and the friction of the triple expansion engine is much greater than with the compound engine under similar conditions. This statement, however, must not be taken in any sense as advocating the use of the compound engine in preference to the triple expansion engine or vice versa, as I am fully satisfied that when applied under proper conditions, each will show the best relative economy. As an illustration of engine friction and its effects on commercial efficiency, I will say that I recently have made comparative tests that are interesting.

1. I tested a triple expansion non-condensing engine. The indicator cards and electrical instruments showed the following readings:

Friction cards showed........................		15.9	h. p.
The same engine tested under load of 260 amperes at 118 volts...........	41.1 Elec. h. p.		
Indicator cards showed.......	h. p. cyl.	34.9	h. p.
“ “ “	Int. “	22.0	“
“ “ “	L. P. “	12.7	“
	Total h. p.	69.6	h. p.

Commercial efficiency 59 per cent.

2. I then disconnected the low pressure piston and run-

ning gear, using the engine as a *cross-compound* non-condensing.

The readings were as follows:

Friction cards. Total friction................	9.6	h. p.

showing a saving of 6.3 h. p. in engine friction of the compound over the triple expansion engine.

3. The engine thus arranged was then tested under load, with the following results:

Under load: 235 amperes at 118 volts.....	37.17	Elec. h. p.
Indicator cards, h. p. Cyl..............	32.8	h. p.
" " Int. Cyl..............	20.8	"
Total Indicated h. p.	53.6	"
Commercial efficiency,	69.3	per cent.

This shows an increase of 10.3 per cent. in commercial efficiency of the cross-compound non-condensing over the triple expansion non-condensing.

The above results show the importance of engine friction as a factor in economy; they show how the low cylinder may drag down the engine; they do not prove that all triple expansion engines are less economical than compounds, but it is evident that in this particular instance the triple expansion engine was not so fortunately placed as to work under the best conditions. Another very important point is that it also clearly shows that even under most favorable conditions, triple expansion engines of so small a size cannot be economical. As the size of the engine is increased, its efficiency increases until we reach a capacity where the triple expansion engine surpasses the compound in efficiency. Similar comparisons may be made between simple high pressure and compound engines.

The use of compound and triple expansion engines is leading rapidly to the designing and constructing of direct driven multipolar dynamos of various capacities. The desire for direct driven armatures originally inaugurated the use of high speed engines for electric lighting.

In connection with the matter of dynamo armatures coupled direct to engine shafts, we are reminded of the fact that the original steam dynamo invented by Mr. Edison and put in operation in 1880 at Menlo Park, combined a Porter-Allen engine with the direct coupled dynamo; also that the Pearl street station of the Edison Electric Illuminating Company of New York City, started in September, 1882, was supplied with six high speed engines and direct coupled dynamos. The exhibits of the Edison Electric Light Company in the Paris Electrical Exposition of 1881, in the Crystal Palace Exposition in London of 1882, and in the Philadelphia Electrical Exposition of 1884, all contained high speed engines with direct coupled dynamos. We are thus not at this time inaugurating the application of a new type of apparatus but simply seeking to combine an improved form of dynamo with a higher economy type of engine.

What we must also recognize as a fact of great importance is, that where several units are required for generation and supply of current for central station distribution, the regulation of the dynamos must be independent of the regulation of the engines, as it is well-known that the engines cannot be depended upon to maintain absolute constancy of speed under changes in load. Each delivering dynamo unit requires independent regulation to bring its current as delivered into the system, up to the normal pressure of that system.

Mr. James Milne has severed his connection with the Keegans-Milne Co., electrical engineers of Montreal, and accepted the position of superintendent and electrical engineer of the Toronto Incandescent Light Co., a position for which his extensive experience well fits him. Mr. Milne has seen a good deal of electrical work in responsible positions, one of which was that of installing and superintending the fine exhibit of the Edison system at St. Johns, N. B., at the very successful exhibition given in that city in 1889.

A BIOGRAPHICAL SKETCH OF THE KHOTINSKY ACCUMULATOR.—VII.

BY

Capt. A. de Khotinsky

From this period dated the origin of my electrodes (Type R) for speedy charging and discharging. In the block station already mentioned I used glass instead of wood for the first time as the insulating part for the electrodes as shown in Figs. 31 and 32.

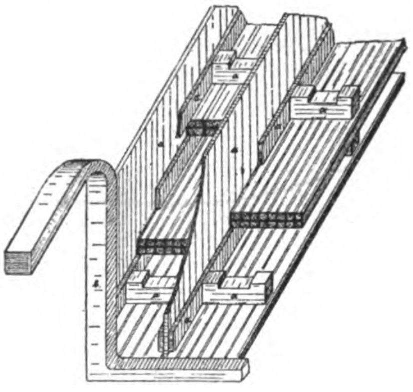


Fig. 31.

In the year 1887 the Tudor accumulators were put on the market, and they were offered at such a cheap price that my company could not compete with them, and I therefore devoted myself entirely to the manufacture of glow lamps. The rapidly extending market led us to build a large factory for their manufacture at Gelnhausen, Germany. The enormous increase of the electric lighting industry, especially in the establishment of central stations for lighting cities, which had taken place in Germany, created a demand for accumulators, and converted more and more to their use, even among those who had been its antagonists. By reason of this change the Tudor accumulator could obtain speedy and widely extended introduction under the continued raising of its selling price.

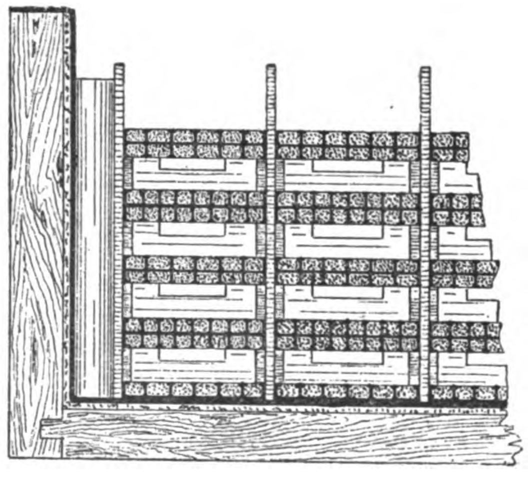

Fig. 32.

In the years 1888 and 1889 I had so developed my company's factory for glow lamps that my absolute personal attention was no longer demanded, and I had more time at my disposal. The changed conditions in the manufacture of accumulators induced my company to commission me, in the summer of 1890, with the erection of an accumulator factory of their own, adjoining our glow lamp factory at Gelnhausen, and, on account of all previous experiences with accumulators, considered themselves more warranted in taking into their own hands the manufacture of accumulators on an extensive scale.

The practice of later years had proved it to be a mistake to lay down several rows of electrodes flat over each other, because the gas, which collected at the lower part of each layer, insulated the under surface from the electrolyte and interfered with their activity. Hence the element could not deliver the capacity for which it was manufactured, and the strips had to bend. I observed this fact the first time in making a battery in Cannstadt, which was ordered for lighting a car on an Italian railroad. When I took the electrodes out of the trays from such cells as did not give the calculated capacity, it was seen that on the lower side of the negative strips in several places, but especially on the top of the connecting strip, the color was uneven and the whole electrode had bent downward, as shown in Fig. 33. At the points *a a* the color was a yellowish gray, and in scraping out the active material it was found that in those places no chemical action whatever had taken place. On examining the positive electrode I found that the strip almost always had bent upward, and only in rare instances in any other direction. Where the bend was highest no action of the filling showed itself, while the action increased in inverse proportion to the intensity of the curve. Fig. 34 shows this effect.

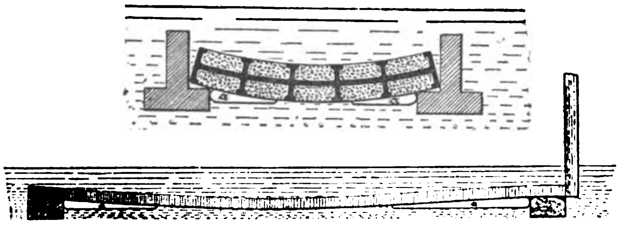

FIG. 33.

To avoid if possible, the collection of gas, I made holes in the electrode along its central line, but soon found that the gases only escaped in this way, when the perforations were made very large, even up to 8 mm. This circumstance led me to lay the electrodes on their narrow side as shown in Fig. 35. The negative electrode I soldered firmly to the inner coating of the trays while I insulated the positive by wooden strips saturated with paraffine. This arrangement I used in batteries for railroad cars, while in stationary accumulator batteries to promote the escape of gas, I either placed the whole tray at an angle of 5° to 8° from the vertical position, or laid the electrodes themselves in the trays at such an inclined angle. I could not bring about a thorough remedy by a change in the shape of the electrode, because the manufacture of electrodes was not in my hands and it was not advisable to give another method of manufacture to a strange factory.

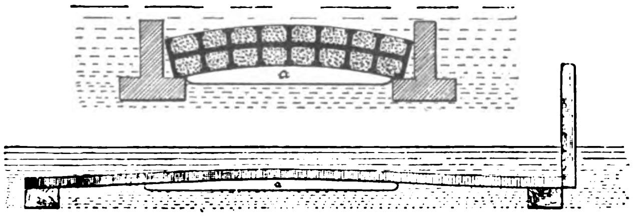

FIG. 34.

Another trouble which had shown itself was the difficulty in mounting several layers of electrodes over each other and the fact that the destroyed positive electrodes, which were always at the lowest layers, had to be removed by taking out those above them, and which were frequently broken in the operation.

The new type of my accumulator constructed in 1890 and 1891, which my company now manufactures, is the result of all previous observations and improvements; the deficiencies having been removed by many years' practice. I have given the electrode its present position on its longer edge for the following reasons: To give the forming gases the most perfect liberty to escape while charging; to insure the most even action over the whole surface; to diminish the inner resistance, while permitting the electrodes to be laid very closely together; to facilitate the mounting of the cells and the changing of consumed positive strips; to facilitate the examination of the cells.

I have constructed an electrode of several horizontal strips laid over each other for the following reasons: To satisfy the great demand for cells of greater capacity, in which the trays may always be easily handled; to avoid the warping and bending which must occur in all plates by the unequal work to which the whole surface of the plates is exposed on account of the greatly varying density of the acid in the different layers in the vessel, by fusing the horizontal strips together at certain distances from each other.

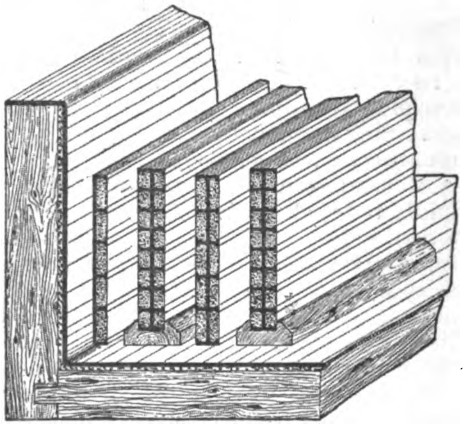

FIG. 35.

Every strip may so expand in proportion to its straining without encroaching upon and drawing the other strips with it by its own motion.

IGNITION TEMPERATURE OF ELECTROLYTIC GAS.

MESSRS. F. and V. MEYER, upon passing electrolytic gas at the ordinary atmospheric pressure through a glass tube contained in a cylinder of sheet iron, dipping into a bath of boiling zinc chloride, noticed that if the bath is set boiling and then the gas be passed, a very considerable explosion takes place at once; if the tube, however, be filled with electrolytic gas, and then introduced into the bath of boiling zinc chloride, water is formed *without* explosion. If the passing of the gas be stopped, then the bath heated to boiling point, a forcible explosion may be obtained by simply re-starting the current of gas. Determinations of the temperature showed it to be 730° Centigrade. Next, zinc bromide was taken for the bath, but with this no explosion could be obtained; the temperature in this case was 650° Centigrade. Hence the temperature of ignition must lie somewhere between 650° C. and 730° C.

MR. J. STANFORD BROWN, electrical engineer and expert, who at present is superintending the building of an electric railway at Camden, N. J., was in the city, November 8. He came home to vote, "and we hav'n't seen him since."

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 203 *Broadway, New York City.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

VOL. XIV. NEW YORK, NOVEMBER 23, 1892. No. 288.

Each adaptation of electricity has its special needs, which every other is bound to respect, and nothing is gained by attempts to exclude or hamper anyone of them.—E. R. Weeks.

OIL VERSUS AIR AS AN INSULATING MEDIUM.

THE recent projects of long-distance transmission of power at high potentials have served to bring out for consideration the best methods of insulating conductors, and most prominent among those proposed have been the insulating oils. These have been suggested for employment not only in connection with the well-known type of oil insulators, but also as completely surrounding the conductor placed within a tube. The claims made for oil as an insulator for high potentials have been based on a few isolated experiments, and hence any contribution to our knowledge on the actual insulating powers of these liquids as compared with air must be regarded as eminently timely and valuable. In the paper which Dr. J. B. Williams read before the American Institute of Electrical Engineers at Chicago, at its last annual meeting, not a few of the popular errors with respect to oils as an insulating medium were pointed out. The paper has now been issued. Our abstract, on another page, shows the enormous differences which may exist between the various types of oils, and even between the same oils under different conditions. While the air is shown to be superior in insulating qualities to any of the oils, its employment in general is, of course, dependent upon the condition that moisture can be excluded from the conductor. Oils themselves have been shown to be by no means unaffected by the presence of moisture, and it must, therefore, finally resolve itself into a question of comparative ability to exclude moisture, and when so considered it is probable that the oils will obtain a supremacy over air. It was to be regretted that sufficient time was not at disposal on Tuesday evening last to enter more fully into the tests of insulated wires. Dr. Williams's method is exceedingly simple and effective, and will, without doubt, be more generally used, now that its advantages have been clearly pointed out.

CENTRAL STATION ECONOMY.

MUCH has been said and written on the means for attaining the highest economy in electric central stations. The subject is one which will well bear further discussion, for, after all, the success of any industry must ultimately be gauged by the dividends which it is able to earn. In the early days of electric light and power distribution, stations were, as a rule, badly designed in the light of our present knowledge, and yet not a few of them have paid dividends and still continue to do so. On the other hand, it is hardly to be wondered at that after a lapse of a few years many of these badly designed stations have been found to be so badly handicapped, that alterations amounting practically to re-building were found to be necessary in order to maintain them on a paying basis. Wherein true economy in construction exists, and how to obtain it, may still therefore be considered a question of the greatest importance. It is from this standpoint that Mr. J. H. Vail, the well-known electrical engineer, discusses the construction of central station plants. Beginning with our last issue, Mr. Vail, whose experience in this direction has been second to none in this country, shows what things are indispensable to success, and again, what mistakes are to be avoided. The engine and boiler plants especially have received attention at his hands, and the comparisons which he draws as between the efficiency of the compound and triple expansion engines embodying the results of actual tests, bring strongly into relief the advisability of giving every detail of the plant thorough consideration before beginning construction.

LIGHTNING PROTECTION.

WHEN we consider the enormous damage which a single thunder storm can accomplish in electric light and railway power stations, it becomes a matter of the most serious consideration to afford adequate protection from lightning discharges. Recent experience has shown, however, that it does not always suffice to take care of a direct lightning discharge but that the charge which accumulates on the line by the inductive action of passing charged clouds must be taken care of if injury to apparatus is to be avoided. Again it has been shown that overhead circuits have nodal points, exactly similar to those mapped out by Hertz in his experiments with oscillating discharges and so graphically shown by Mr. Tesla in his high frequency work. The location of points for grounding circuits must therefore be made with a view of avoiding such nodal points, and the wisdom of having numerous grounding-points requires no further discussion. A device therefore, to take care of the accumulated charge, as well as an isolated and sudden lightning stroke, at the same time avoiding the dangerous nodal points, must claim more than ordinary attention, and as such the "tank lightning arrester" of Mr. Alex. J. Wurts, described in our last issue, is entitled to more than passing notice. Although but a comparatively short while in use, the results already attained with it have shown its practical value in a high degree.

ELECTRIC RAILWAY DEPARTMENT.

THE NEW PLANT OF THE BIDDEFORD & SACO RAILWAY COMPANY.

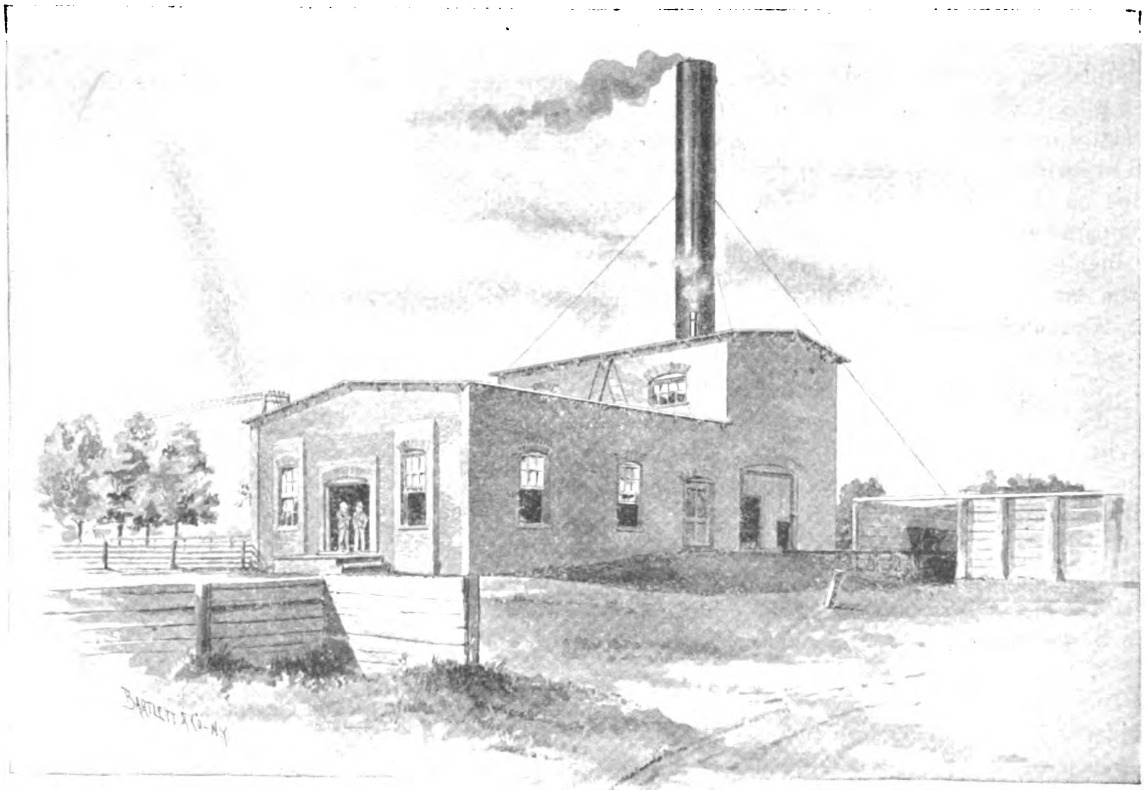
BY

A. C. Shaw.

I.

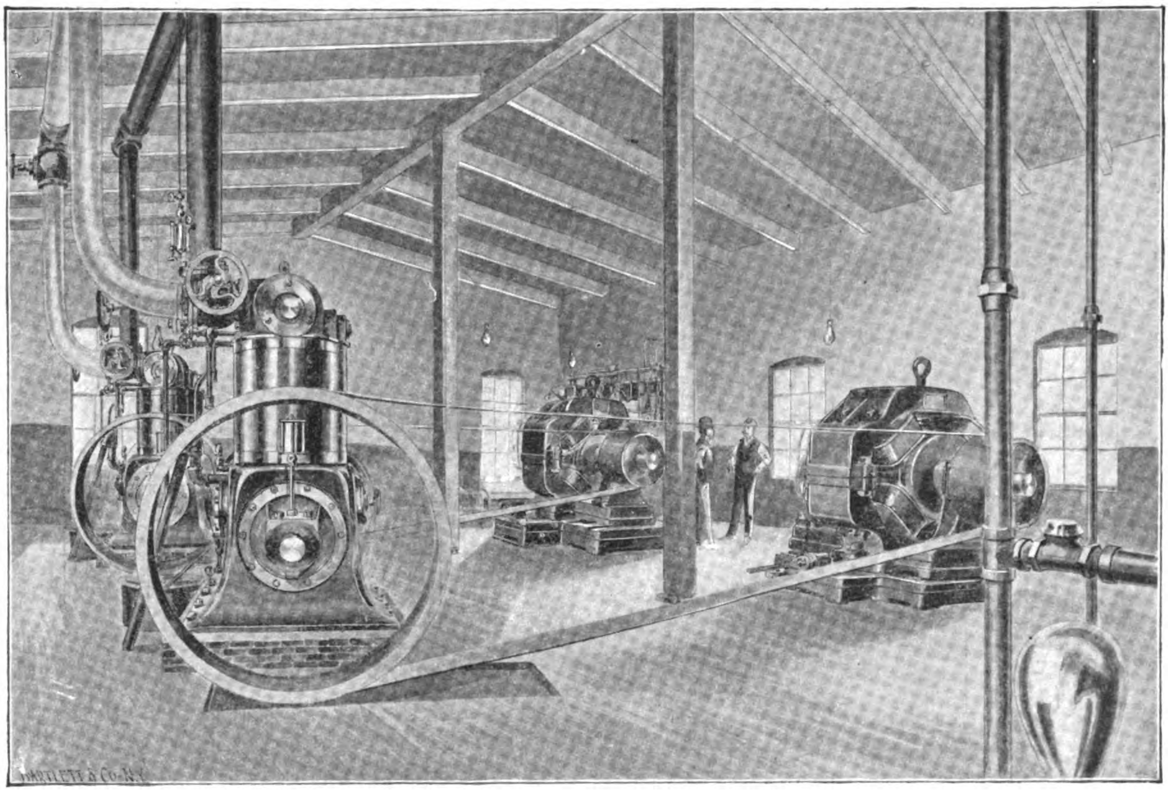
THE readers of THE ELECTRICAL ENGINEER will remember a series of articles published in these columns from the pen of Mr. Wm. Lee Church, entitled "Points on Power Stations," in which Mr. Church sought to show the proper proportions of boiler, engine and generator capacity in a well designed power station, specially devoting his attention to stations of moderate capacity. These articles elicited considerable discussion, and were widely read by experienced electrical engineers, who doubtless, though perhaps differing from Mr. Church in his practice, will now be glad to read a description of a power station, the steam plant of which was entirely designed by Mr. Church, and which may be looked upon as a working example of the lines laid down by him. Such a plant has recently been installed at Saco, Me., for the Biddeford & Saco Railway Company, Messrs. Westinghouse, Church, Kerr & Company, acting as engineers for the plant, and having entire charge of the installation of the steam plant, and the General Electric Company furnishing all the electrical apparatus. Though the plant is not a large one, it bears out in a wonderful way the conclusions reached by Mr. Church in his arguments, and has achieved such a success as an economical producer of power, that an account of its construction, and a few details of the results of extensive tests will be found interesting.

The Biddeford & Saco Railway Company was organized in 1885, with a capital of $100,000, its purpose being at that time to build a horse railroad between the two towns. The charter was subsequently amended in 1887, so that rights were secured to extend the road to Old Orchard, and the road was built and opened on July 9th, 1888. As a business venture, however, the road was never a success (the bulk of traffic being in the summer time), owing to the necessity of buying horses in the spring for the summer trade, and disposing of them at a heavy loss in the autumn, when the summer traffic to the beach ceased. The question of applying electricity was agitated in 1890, and application was made to the city governments for permission to erect poles and string wires during the same year. The permits were not granted till April 7th, 1891, too late to build a station and equip the road for that summer's business, though the poles were erected and the rails bonded that fall. Soon after, a contract was made with Westinghouse, Church, Kerr & Company, for the erection of an efficient station, giving them *carte blanche* to install whatever they thought best in the way of a steam plant, and holding them responsible for its success. In the following February, 1892, the contract for the electric generators and car motors, and general electrical equipment was placed with the Thomson-Houston Electric



BARTLETT & CO. N.Y.

GENERATING STATION OF THE BIDDEFORD AND SACO RAILWAY COMPANY; SACO, MAINE.



Engine Room, Biddeford and Saco Railway Co.; Saco, Maine.

Company. The plans and specifications were all prepared by Westinghouse, Church, Kerr & Company, and the building was erected in the spring of 1892.

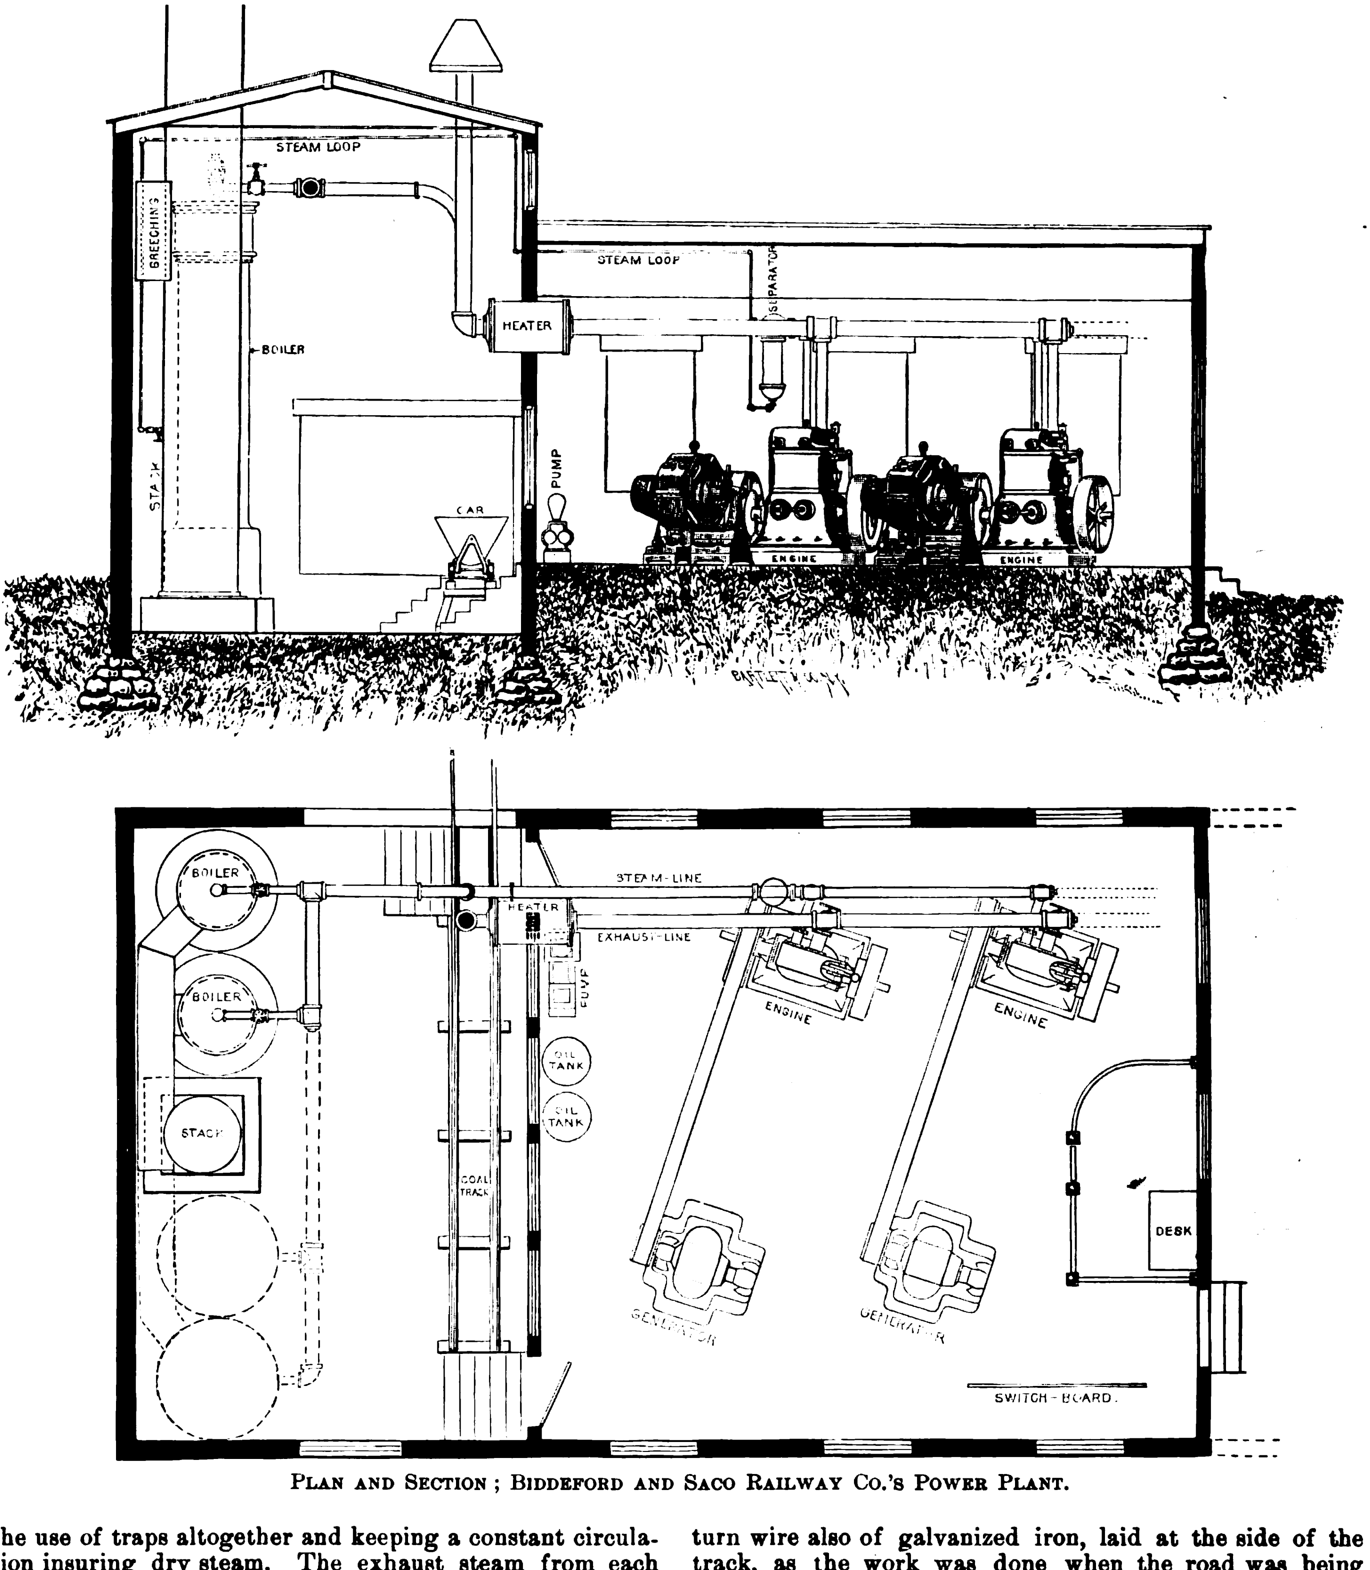
II.

The building is of brick on granite foundations and measures 62 feet long by 36 feet 6 inches wide, with ample ground facility for increasing when desired. The engine room, a ground plan of which is shown on page 496, and a general view on this page, measures 37 feet long by 34 feet 6 inches wide and is 18 feet high, having an ordinary wooden roof covered with tar and gravel. In this room are two Westinghouse compound non-condensing engines, each of 130 rated h. p. at 125 pounds steam pressure, with an ultimate capacity of 150 h. p., which run at a speed of 300 revolutions per minute. Each engine has two cylinders 12 inch and 20 inch diameter by 12 inch stroke, one driving pulley 60 inch diameter by 14 inch face, and is belted direct by means of a 12 inch double ply leather belt to the generators, the distance between the centre of the engine and generators being 18 feet. These engines are guaranteed to develop their indicated horse power non-condensing on a consumption of 25 pounds of dry steam per hour at 125 pounds pressure under full load, and 28 pounds under one-third load. As will be seen by looking at the plan, the engines and generators are set obliquely to the line of the walls, the chief reason for such setting being to economize space. By such an arrangement the main shaft of each engine can be removed at any time, should it become necessary, without interfering with the other engine, which could not be done were the two shafts in direct line with each other, except at the sacrifice of considerable floor room. It also places the commutators of the generators in such a position that the attendant can never be in danger of coming in contact with an adjacent generator, and gives generally more space about the engines and generators. The two generators are of the regular Thomson-Houston M. P. 90 type, of 120 h. p. each, furnished by the General Electric Company. The switchboard, which is of the usual skeleton type, stands in one corner of the engine-room, and is built of Southern pine. It contains the usual voltmeters, ammeters, circuit breakers, lightning arresters, and other necessary apparatus. In the engine-room is also situated a No. 4 Deane boiler feed pump, and two Hancock inspirators, and one Locke damper regulator.

III.

The boiler-room measures 22 feet by 34 feet 6 inches and is 28 feet high, with wooden roof covered with tar and gravel. It contains at present two 100 h. p. Manning vertical boilers, built by the Bigelow Company, of New Haven, Conn., of the best steel plate, rolled in a single sheet, without circular seams, and fitted with shaking grates, pop safety valves, and extra heavy gun metal mountings. The boilers are 48 inches diameter in the waist, and 65 inches diameter at the furnace, and have a total height of 23 feet 6 inches. The grate area is 18 square feet, and there are 112 tubes 2½ inches diameter and 15 feet long, having a heating surface of 791 square feet, the total heating surface being 1,138 square feet, equivalent to 11 square feet to the h. p.

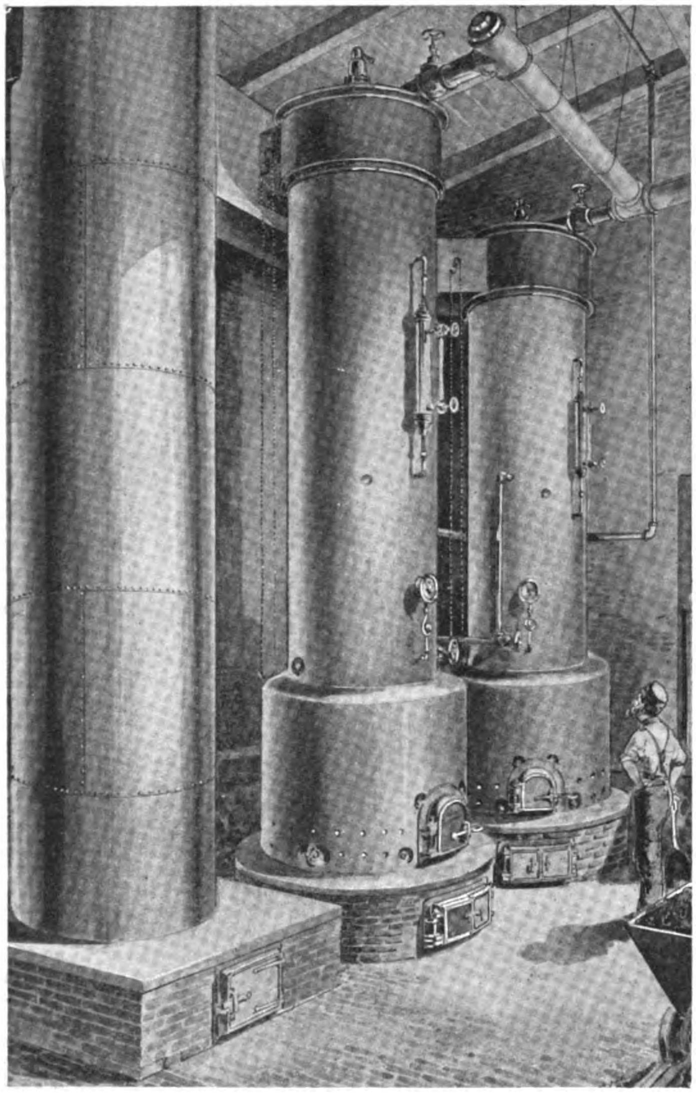
The chimney is of iron, 54 inches diameter, and 60 feet high, and rests on a cast iron plate on a granite foundation. It is connected to the boilers by the usual smoke flues, fitted with dampers, and is supported by iron guy rods. From each boiler runs a 5 inch wrought iron steam pipe, connecting with an 8 inch wrought iron steam main which is carried horizontally over the engines, and which is sufficient for double the present capacity of the station. This main passes through a horizontal separator, at the point where the connection is made to the first engine, and which is shown in our engraving of the elevation of the building. From this main drops a vertical copper bend 5 inches in diameter to each engine, having a long sweep curve to provide for expansion and contraction, and tapering in its length to bring the proper reduction of size. All steam piping is equipped with long turn fittings, and stop valves are placed in the boiler supply pipes, and at the junction of each copper main with the overhead main steam pipe, in addition to the throttle valve on each engine. All the water of condensation, primage and entrainment which is collected in the separator is automatically returned to the boilers at boiler temperature by means of the remarkable device known as the steam loop, avoiding the use of traps altogether and keeping a constant circulation insuring dry steam. The exhaust steam from each engine is carried vertically by a 7 inch pipe to a 10 inch exhaust main, which runs horizontally, at the same level as the steam main, through a 200 h. p. National feed water heater, set horizontally in the boiler-room, where it passes vertically up through the roof and exhausts into the atmosphere through a Woodbridge exhaust head.



Plan and Section; Biddeford and Saco Railway Co.'s Power Plant.

IV.

The tracks of the company, which cover a distance of six miles, are practically the same as when horses were used, the ordinary 35-pound steel T rail being still in service, while a tram rail laid on stringers is used in the vicinity of the city. These rails have been bonded with galvanized iron wire, and connected to an underground return wire also of galvanized iron, laid at the side of the track, as the work was done when the road was being operated by horses. In addition to this ground return, old gas pipe has been driven vertically into the ground at short distances along the track wherever the ground was soft enough to permit it, and the ground wire firmly soldered to it. Plates attached to the ground wire were also sunk into streams wherever such were crossed, and everything done to make the return circuit as efficient as possible, the advantage of such methods being amply borne out by the remarkably good tests which have been made on the road. The poles for the overhead construction, in the vicinity of the city, are of squared Southern pine, and on the part of the road running through the country between Saco and Old Orchard, round cedar poles are used. The poles are set 6 feet in the ground, and extend 22 feet above the surface of the road. The span wire is of silicon bronze, and the trolley wire of No. 0 hard drawn copper, held in place by the regular form of Thomson-Houston insulators. Two feeders, triple braided, run from the power house, one No. 0000 wire going to Old Orchard, and one No. 000 wire to the Biddeford end of the line. At present the company have 16 cars for service, four being 12-foot closed cars, six 25-foot open cars, and six 25-foot trailers. Each motor car is equipped with two 25 h. p. W. P. motors, built by the Thomson-Houston Electric Company, and the new type J. controller, it being of interest to know that this is the first road completely equipped with these controllers. It is also a matter of general interest that, notwithstanding the unfavorable financial condition of the company when operated by horses, as soon as the road had been operated electrically during one summer, it gave capital so much faith in the enterprise that the issue of $50,000 in bonds to cover the electrical construction was immediately taken up by local banks, and that in fact there was considerable competition to secure them. The officers of the company are as follows: E. H. Banks, president; C. H. Prescott, secretary and treasurer; and G. C. Towle, superintendent. The directors are: E. H. Banks, C. H. Prescott, Joseph Goach, J. F. Nourse, all of Biddeford; Franklin Nourse and S. S. Mitchell, of Saco; and Charles P. Pratt, of Worcester, Mass.



Boiler Plant, Biddeford and Saco Railway.

V.

Quite recently a most complete and exhaustive set of tests to determine the operative efficiency of the mechanical and electrical equipment of the station was made by the Massachusetts Electrical Engineering Company of Boston, a few details of which will be found interesting to our readers. In estimating the economy of an electric railway, and in the comparison of different roads, a fundamental factor is the operative economy of the mechanical and electrical equipment, apart from wages, interest account, etc. This is usually expressed as the cost in cents per car mile of the power expended in operating the system, and the tests which were made were undertaken for the distinct purpose of establishing this factor. The test lasted for two days, and embraced careful readings of the coal consumption, the amount of water evaporated, the indicated horse power of the engines, the electrical output of the station, and at the same time careful readings were taken by voltmeter and ammeter on the cars. The coal was all carefully weighed, and due allowance made for unburned coal found in the ashes in the morning. The water for the boilers was also carefully weighed, the exact amount pumped into the boilers being accurately determined. The engines were indicated occasionally to determine the conditions under which they were running, and the electrical output of the station was measured at intervals of one minute throughout the entire run. Every precaution was taken to operate under usual conditions, in order that the test might fairly represent an average day's run.

The net result of the two days' test may be stated as follows:

Cost of coal per car mile..........................	1.51c.
(with coal at $4.67 per ton.)	
Pounds of coal per car mile......................	7.26
Pounds of water evaporated per pound of coal, actual conditions..................	8.92

The engines, dynamos, and station equipment were in excellent shape, but the plant was not working under conditions favorable for the best economy in coal consumption, for the reason that the average load was just sufficient to make it necessary to run two engines and dynamos, but not enough to load them to good advantage.

The results in detail are as follows:

	Average of two days.
Total car miles per day...................... ..	701.
Mean electrical horse power output.............	50.
Maximum electrical horse power output.	171.
(reached only once during two days' run.)	
Pounds of coal burned per day..................	5080.
" " water evaporated per day............	45800.
" " water per pounds of coal............	8.92
" " coal per car mile....................	7.26
Cost of coal per pound........................	0.208c.
Cost of coal per car mile.............	1.51c.

The total rated capacity of the various parts of the plant is as follows:

Boilers 200 h. p. at 100 pounds steam pressure.
Engines 260 h. p. at 100 pounds.
Generators 240 electrical horse power.

This is nearly in the ratio of boilers 80, engines 104, generators 96.

The actual mean output during the test was only 50 electrical horse power, which is but 20 per cent. of the capacity of the plant.

The maximum observed electrical load was 171 horse power, which is about 242 per cent. above the average load, and but 71 per cent. of the capacity of the station.

As stated before, the most favorable results could not be expected under these conditions.

In order to determine the economy of operation under different conditions records have been kept by the superintendent in charge of the station of the coal burned and car miles run during each day. These records show that though the mean cost per car mile when running on the average of about 700 car miles a day is 1.51 cents, yet when on Sundays the traffic increased to about 1,000 car miles a day, the fuel cost was reduced to a fraction less than one cent per car mile, a result which has not only pleased the designers of the station, but which has given the most eminent satisfaction to the Biddeford and Saco Railway Company, who accepted and paid for the power plant before the maturity of the term under the contract. As for the financial returns on the investment, it is stated that in the month of July alone they earned their full annual dividend on the capital stock, assuming the road to only pay current expenses for the remainder of the year.

REGULATION OF WATER WHEELS IN ELECTRIC RAILWAY WORK.

BY JOHN A. CROSS.

In reply to the communication from Mr. T. E. Pritchard upon this subject, in your issue of Nov. 9, 1892, I would suggest that its title is a misnomer, as he describes a method of adjusting the load attached to a water wheel or wheels, and not to the regulation of the power developed by the wheels. This particular case is one of the two I referred to in a previous letter to the ENGINEER.

I would reiterate my objection to Mr. Pritchard's method, viz., that by far the larger proportion of the water powers used for electrical purposes are dependent upon a limited supply of water and cannot afford such waste. The problem is one which can be solved, as engine regulation has been, though probably not with so great a success. No one doubts the ease of adjusting the output of an electrical plant driven by water wheels running at "full gate" at all times, but this method cannot be commended for general use, though it may be a good makeshift.

Operating an electric plant driven by water, for railroad purposes, gives an excellent opportunity for the use of storage batteries. They can be connected so as to absorb power from the generators when it is not required on the circuit, and return this power to the circuit in case of sudden and excessive load. This method does not entail any waste, such as is unavoidable in Mr. Pritchard's method, though its efficiency, electrical and commercial, must be examined for each set of conditions. In addition to the above, the wheels can be materially assisted in maintaining the proper speed, by one or more fly-wheels, properly designed and located. The wheels themselves, may also, I think, be made to regulate closer than is customary at present.

Another point of equal, or greater, importance is the efficiency of the water wheels. There is a large number of wheels in every day use, most of which reach from 80 to 85 per cent. efficiency at full load, but at half load their efficiencies will vary as widely as the locations of the works from which they emanated, and anywhere from 40 to 75 per cent.

This point has a very serious bearing upon the design and operation of electric central stations, with limited water supply, and especially upon those for lighting purposes, varying in importance according to design, and the load diagram.

THE NEW YORK RAPID TRANSIT FRANCHISE.

AFTER two years of work by the Rapid Transit Commission upon the perfecting of plans for the best method of taking care of New York's enormous growth of travel, a definite conclusion has been reached, and the franchise granting the right to construct and operate the proposed road for 999 years will be sold in the rotunda of the City Hall on Thursday, December 29, at noon. The purchaser will be required to pay 10 per cent. of the bid when the sale is made, $1,000,000 in cash or good securities within the first five days as a guarantee of good faith, and the balance within thirty days. In addition to this, the successful bidder must pay the expenses of the commission, amounting to about $90,000, together with such compensation for services as the Supreme Court may determine. The company must have $50,000,000 capital stock in $100 shares, and must furnish a bond for $2,000,000 to secure the city against damage to property. That part of the road between the City Hall and 14th street is to be completed within two years; below the former and above the latter, up to 53d street, within three years; and between 59th street and the Harlem within four years after the acceptance of the bid. The road will be a four-track underground electric railway, extending from the Battery, under Broadway and the Boulevard, to Fort George, and thence to the Yonkers City line. At the southern terminus a loop will extend under State street to South Ferry and back to Broadway, under Whitehall street, and another loop will run around City Hall park, with a station at the bridge. At 14th street and Broadway a branch will run up Fourth avenue to the Grand Central Depot. There will be both way and express service, and no grade crossings. The way stations will be at short distances from one another, and the express stations about a mile apart. On the express line it is expected to make the run from Fort George to Battery park, a distance of 10½ miles, in twenty minutes. This includes ten stops.

The cost of the work is estimated at $60,000,000.

TRIAL TRIP OF THE SYRACUSE STORAGE BATTERY CAR.

THE SYRACUSE STORAGE BATTERY Co., after a long series of experiments to perfect their system, gave a public exhibition of the performance of their batteries recently on the track of the People's Line railroad in Syracuse, N. Y. The trip was made with 39 passengers, among them the following stockholders: Mayor Jacob Amos, C. W. Snow, Charles Hubbard, W. F. Pardee, C. M. Warner, Thomas Hooker, I. C. Reed, Riley V. Miller, I. Henry Danziger, A. D. Sanford, E. F. Rice, T. S. Croley, W. S. Andrews, H. P. Cady, C. L. Pack, E. L. Loomis, and Lucius Moses. The run was entirely satisfactory and steep grades were climbed with ease. On the steepest grade, one of 12 per cent. and 125 feet long, an 80 ampere fuse burned out when the car was 15 feet from the top. Two fuses, each of 80 amperes, were then tried and failed to carry the current, after which, at the risk of ruining the motor, a piece of copper wire was placed in the fuse block and the car went over the grade without difficulty or injury.

The motor used was a special Rae 30 h. p., single reduction, not wound for great speed, but making 12 miles an hour very readily, while the current was taken from 96 cells weighing 53 pounds each. The Syracuse cell is 7½x8x13 inches in size, the conducting plates are light and the rubber grids take up two-thirds of the space ordinarily occupied by liquid.

Since the first day the car has been running more or less each day, the longest run on one charge thus far made having been 72 miles over a track with few level places and many long grades. The company claim that, with their batteries, cars may be operated at a lower cost than by means of the trolley system. They are delighted with the result of the tests and expect soon to actively push the batteries in competition with those now before the public.

The officers of the company are: R. V. Miller, president; C. M. Warner, vice-president; C. S. Pack, secretary; and Lucius Moses, treasurer.

THE ADAMS ELECTRIC RAILWAY BETWEEN CHICAGO AND ST. LOUIS.

THE prospectus and statement of the Chicago & St. Louis Electric Railway Co. have been announced in the advertising columns of the daily press and it is evident that a new departure in electric railroading of greater scope and magnitude than anything heretofore attempted is actually under way. The company has secured the right of way and has already several miles under construction. Work has been commenced at Edinburgh, Ill., about eighty miles from St. Louis, and one power house is completed. The total length of the air line will be about 248 miles. The work of construction will be immediately started at the Chicago end of the route in Livingston county and built to Edinburgh simultaneously with the construction from Edinburgh to St. Louis.

In addition to generating electric energy to operate the cars carrying the mails and the passengers, it is proposed to furnish current all along the line for supplying light and power in neighboring towns and villages and operating mining machinery in the coal mines situated in the vicinity of the road. It is also intended to supply power where needed by farms.

The company is capitalized at $7,000,000, and it is its intention to open up and improve a section of the country which is rich in coal and agricultural products. The company has secured a coal belt also along its right of way which it proposes to mine and sell, using the slack and culm for running the power stations which will be situated near the mouth of the coal mines. The cars will run 10 miles apart and by a special block system any possibility of collision is, it is claimed, done away with. The road will run above all other railroad crossings, over bridges which will cost about $10,000 each, of which there are 17 in all. There will also be 248 cheaper bridges over and above its line of road at each country road crossing, and a durable fence will be built on either side of it throughout its entire length. As there will be no frogs or switches breaking the main line, nor coaling stations or water tanks, causes of delay will be minimized. The line of road is 36 miles shorter than any present steam route and it is proposed to make the run in three hours. It is the plan of the company to have four standard gauge, rock ballasted tracks, two light-weight outside tracks for local traffic and high-class freight, and two heavy-weight inner tracks for through passenger, mail and express service. The trains on the main track will run through without stop, so that leaving Chicago at 7 a. m., St. Louis will be reached at 10 o'clock. And now for the realization of this daring project!

ELECTRICITY AT THE WORLD'S FAIR UP TO DATE.

BY

H. Norman Collins.

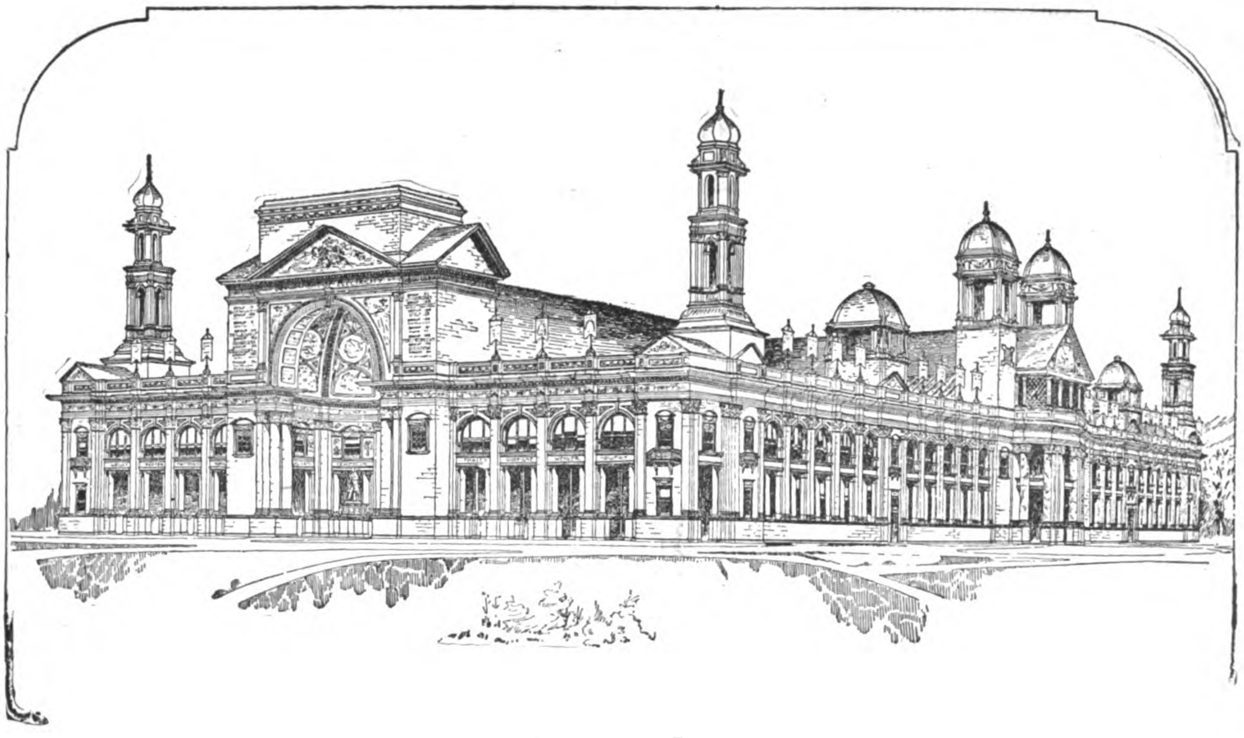
I.—INTRODUCTORY.

Statue of Franklin; Electricity Building.

THE readers of this journal are aware that, from time to time, as matters have advanced I have reported to THE ELECTRICAL ENGINEER the condition of the World's Fair, and the state of the arrangements with regard to electricity. It seems to me that the moment has now arrived when I can make a complete survey of what has been done, and speak with definiteness of plans that will be carried through. Even at this moment, there are many details still unsettled, and of no small importance, such as the question of night and Sunday opening, the lighting of certain buildings, the scope and nature of the electric fountain display; but these are matters which do not affect the accomplished work to which I shall here make reference. Part of what I shall say will naturally be by way of repetition or recapitulation, but it will help in giving a general view of the whole state of affairs.

II.—THE DEPARTMENT OF ELECTRICITY.

This department of the World's Columbian Exposition was organized in February, 1891, under the direction and jurisdiction of the National Commission appointed to control the Exposition, of which Mr. George R. Davis, the Director-General of the Fair, has been at the head. Prof. John P. Barrett, for many years with the city of Chicago as its chief electrician, was selected as the head of the department, and he, in turn, selected Mr. J. Allen Hornsby, a gentleman with an immense amount of push and energetic ability, as his secretary. He added a competent corps of assistants, and they have since the foundation of the department had the complete charge of it.



THE ELECTRICITY BUILDING.

The work of this department comprised the preparing of a complete and accurate classification of exhibits and the reception, consideration and allotment of all applications for space in the Electricity Building. It can be seen that this programme outlined an immense amount of work of a peculiarly detailed nature and requiring the greatest tact to perform to the satisfaction of everyone. It has been carried out with commendable success, and the department is as far ahead in its work as any other connected with the Exhibition, thanks to the diligence and energy of the gentlemen in charge.

Mr. Hornsby, secretary of the department, last September made a trip to Europe as special commissioner of the Exposition and visited all the principal electrical manufacturers and people connected with the industry there, giving them a full and detailed explanation of the objects, advantages and benefits to be derived from the Exhibition. The result of this commission has been that the foreign countries will make a most comprehensive and striking exhibit of all kinds of electrical apparatus, devices and appliances, for which purpose they have been assigned ample and desirable space.

The total amount of space in the Electricity Building to be allotted comprises some 245,000 square feet of ground floor space and about 95,000 feet of gallery space. It is exceedingly interesting to know that applications have been made for three times this amount of space, showing that the fears of the department that they would not have sufficient space to give everyone all they asked for in their building were not groundless. It is, no doubt, true that many exhibitors asked for more space than was actually needed by them, and the allotments have been so carefully distributed and planned that everyone will doubtless be well satisfied and have sufficient area for his requirements. Some of the difficulties of the task of distributing the space may be imagined when, of course, all the applicants naturally wanted to get the centre space on the ground floor of the Electricity Building, but all such questions as these have been handled with admirable diplomacy by the department.

At the conclusion of the dedicatory ceremonies the Electricity Building was practically turned over by the Construction Department, who erected all the buildings, to the National Commission, who will hereafter assume entire charge of it.

Among the many striking features connected with the Fair which will be installed by the Department of Electricity are two 6 foot and one 7½ foot projector search lights which Schuckert & Co., of Nuremburg, have sent to this country. These, it is said, are the largest ever constructed. If a tower is built, they will probably be placed upon it, and if not, it is said, upon the Electricity Building. Mr. Fred. Tischendorfer, representing Schuckert & Co., is now here to assist in this work.

France will exhibit several arc lights of large candle power, such as those used in light-house work abroad.

The Bell Telephone Co. will have a small theatorium, fitted with a large telephone and a trumpet in the roof so that the visitors to the exposition can listen to some of the best bands in Boston and New York.

One of the largest manufacturers of cut glass for electrical purposes will erect a Mooresque pavilion, entirely constructed of the finest cut glass of beautiful and varied hues, on the ground floor of the Electricity Building. This pavilion will be 30 feet in diameter and 75 feet high and be brilliantly illuminated by electricity.

The Department of Electricity have prepared plans and will build a model house fitted as a complete ten-room residence and equipped with every conceivable household application of electricity. Among the uses to which electricity will be put are those of cooking, washing, ironing, operating elevator, sewing machines and various forms of incandescent lighting for decorative and illuminating purposes. Speaking telephones will be installed all over the house and the lights will be arranged so that all are thrown into circuit upon the opening of the door and cut out upon closing it. The house will be warmed in cool weather by means of electrical heaters and cooled during the hot days in summer by a special refrigerating machine run by an electric motor. The special illumination in the Electricity Building will comprise some 500 arc lamps of all the various systems, there being exhibited probably in the neighborhood of some 100,000 incandescent lights.

III.—THE ELECTRICAL ENGINEERING DEPARTMENT.

The Electrical Engineering Department of the Construction Department of the World's Columbian Exposition was organized and established in the spring of 1891. The selection of a competent electrical engineer to have charge of this department was referred by a committee to the Chicago Electric Club and some five candidates were nominated for the position. From these, Mr. Frederick Sargent, one of the best known electrical and mechanical engineers in the West, who had done important work with the Edison Co. and other large concerns, was finally selected. He was appointed to the position of chief engineer of this department to be under the jurisdiction of Mr. D. H. Burnham, chief of the Construction Department. Mr. Sargent selected Mr. R. H. Pierce, a talented electrical engineer who had been connected with the Edison Co. of Milwaukee, and had held other responsible positions, as his chief assistant, and these two gentlemen, aided by a competent corps of assistants, have since had charge and carried out the work of this department. This comprised, among other duties, making plans and specifications for a temporary lighting and power plant, which was done; and a very complete station for this work was erected and thoroughly equipped. For every conceivable purpose in the construction of the buildings for which electricity could be employed, it was used, motors being employed to furnish all the power required by various machinery, which was very extensively described by me in THE ELECTRICAL ENGINEER some time ago in a special article.

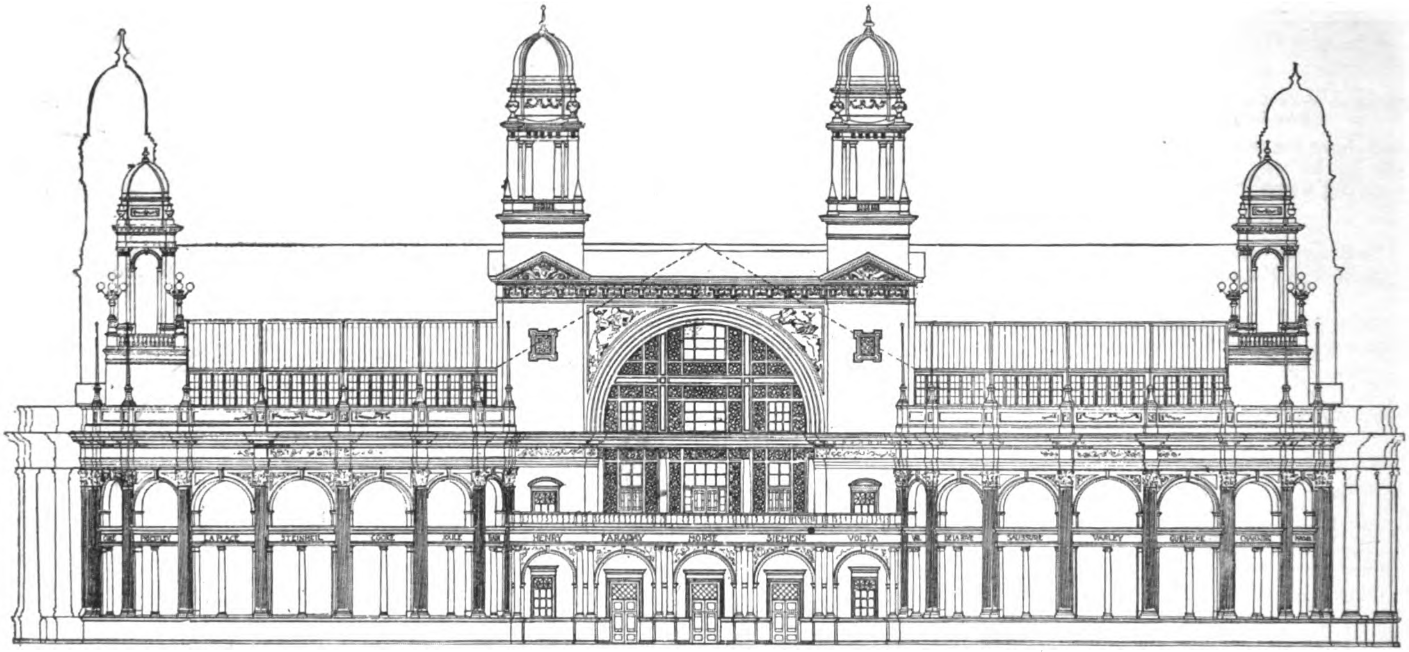
A complete fire-alarm and telegraph system was also planned and constructed and the erection of all the electrical machinery required for all purposes at the exposition during the construction, was carried out. Detailed specifications for the use of bidders for furnishing arc and incandescent lighting and electric power were carefully prepared by Mr. Sargent, and all bids for electrical machinery and apparatus of all kinds have come under his examination, to report thereon to the chief of the Construction Department.

In addition to this work complete plans were prepared for the permanent illumination of the buildings and grounds, and a very perfect and excellent system preventing obtrusive presence of wires was laid out, comprising a special subway to carry the largest number of the wires and cables necessary for arc and incandescent lighting and power purposes, arrangements also being made for putting the remainder of the wires out of sight beneath the structure of an elevated road which is to encircle the grounds and to be operated also by electricity.

IV.—THE ELECTRICAL SUBWAY.

The construction of a comprehensive subway system was designed after due consideration in such a manner as to be suitable for all purposes and at the same time to involve a reasonable cost, giving easy access to every wire for inspection and maintenance.

This subway commences at Machinery Hall and runs north as far as the Electricity Building, at which point it consists of two main sections, each being a complete subway in itself. At the Electricity Building one of the sections is divided into two branches, one running into the building and carrying all the wires necessary for supplying current there, and the other branch going into the Mining Building. The east section runs on in its entirety east as far as the north railroad bridge, where all wires cross the lagoon, and continues north the entire length of the Manufacturers' Building. At the centre of the Manufacturers' Building a section is run into the building. The east section then passes north of the Manufacturers' Building under the Government Building and into the Fisheries Building, which is the end of the subway.



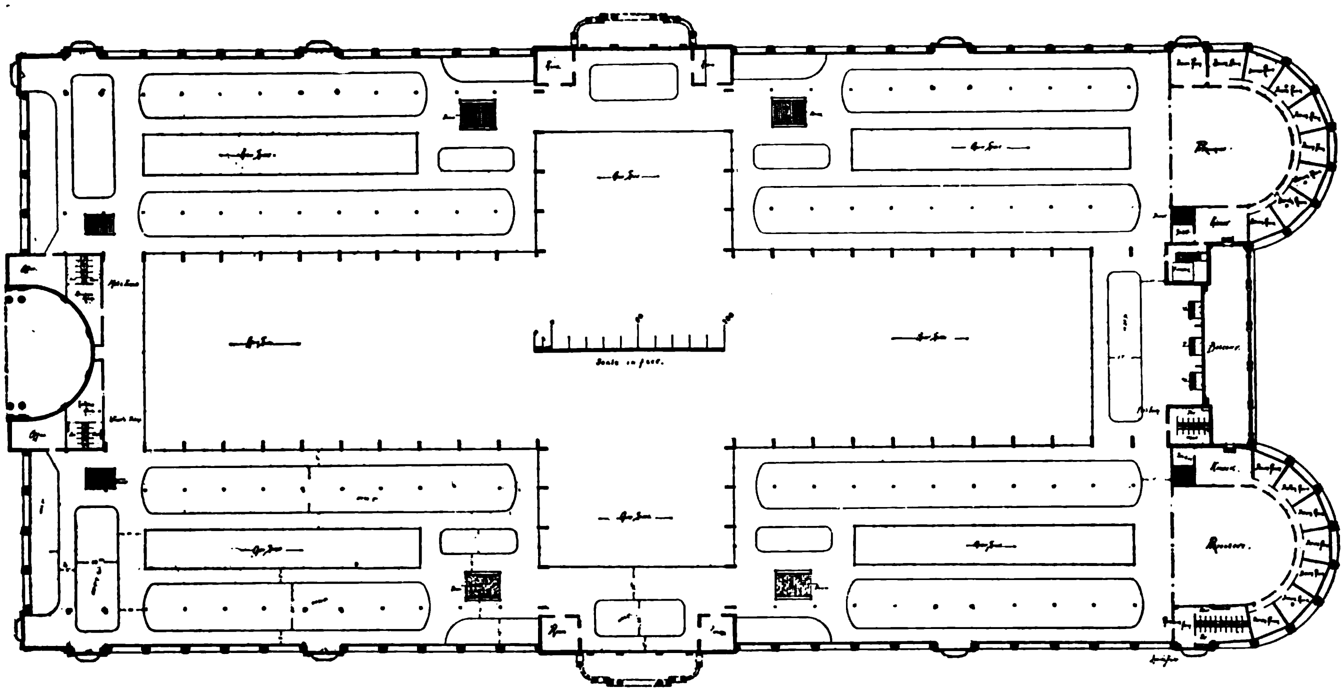
REVISED ELEVATION OF NORTH FRONT; ELECTRICITY BUILDING.

The sections are 8 feet 4 inches x 6 feet 3 inches, and in some places are reduced to 4 feet 3 inches in height, commencing at the turn north of the Government Building.

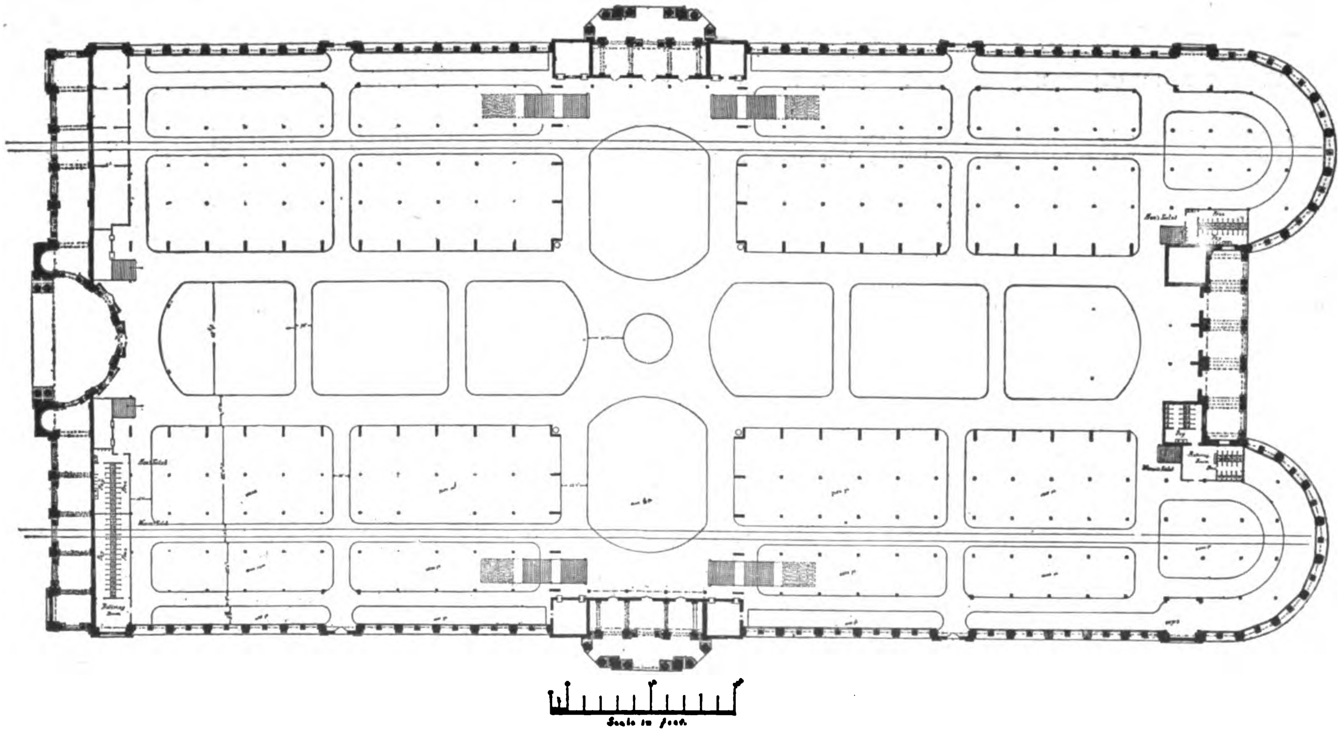
The subway is built of 3 x 8 inch joists and 2 x 8 inch planking, then covered with a metal lath and cement plastering and is lighted throughout by incandescent lamps placed in specially designed sockets made of moulded mica. At frequent intervals on the sides of the subway, cast iron uprights are let into the wall supporting tiers of oak cross-arms upon which are placed the pins carrying the insulators on which the wires are strung. Every upright has a number and also every cross-arm and every pin; and the workmen are supplied with a card of these numbers which gives them the key to every wire and shows to what use it is being put and what current it is carrying. The subway is a very substantial piece of work and is specially adapted for handling the multitude of wires that will be placed in it in the best possible manner. I have had the pleasure of walking through and inspecting it from one end to the other, and find it a very interesting trip to take.

During the recent dedicatory ceremonies a temporary plant to furnish additional lighting for the illumination of the grounds and buildings during that period was installed in the Machinery

Hall. The dynamos were manufactured by the Standard Electric Company, of Chicago, having a capacity of from four to five hundred arc lamps. Additional incandescent lighting had also been provided for. The plant was driven by Ball & Wood engines.



Plan of Gallery, Electricity Building, World's Columbian Exhibition, Chicago.



Floor Plan, Electricity Building, World's Columbian Exhibition, Chicago.

V.—ARC LIGHT POSTS.

The posts upon which the arc lights are to be placed for illuminating the grounds of the Fair will be very different from those which we see in ordinary street lighting and will emulate the beauty of design and workmanship that is so noticeable abroad, where electric lighting is done on lamp posts of architectural iron work of the most artistic and pleasing character. Some of these posts are designed to carry three lights and the others are for single lights. A contract for the single light posts of a thousand or more has been awarded to Mr. A. B. Ayers, of New York, and the work of furnishing them is under good headway. These posts are of such a height that the lamps are about 17 feet from the ground, the column being supported in a cast iron base on which is a cast iron shell 7 feet 4 inches in height. To the top of this shell is fitted a wooden pole through which the wires leading to the lamp run, and a fancy wood framework supports a handsome sheet metal hood made of galvanized iron and strengthened with iron straps connected to the iron framework. The base of all the arc lamp columns will be secured by lag screws to the wooden foundation and the contractor will erect the posts and fit the different sections together. The color which the posts are to be painted has not yet been determined upon but will be selected by the Director of Works.

Prof. Barrett reports that there will be about 1,000 electrical exhibitors, of whom 700 will be American. A great many of the exhibits will be of a very interesting nature historically, as well as technically, and alongside the latest productions of the great telegraph, telephone, electric light and electric railway companies of the present day will be placed the relics of the forefathers of the art.

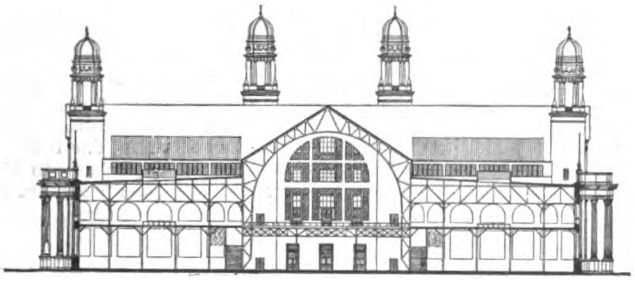
VI.—ELECTRICITY BUILDING.

The Electricity Building is now nearing completion and is one of the most handsome and imposing of the magnificent constructions composing the Exposition proper. The assignment of space in the building has now been completed, but no official authentic figures have yet been given out as to the amounts of space allotted to the different electrical industries. As regards the amount of space awarded to foreign nations, the following list is probably approximately correct:

Germany	20,000	square feet.
France	16,500	" "
Great Britain	8,500	" "
Canada	4,000	" "
Italy	2,500	" "
Belgium	2,000	" "
Austria	1,000	" "
Spain	1,000	" "
Sweden	1,000	" "
Mexico	600	" "
Russia	200	" "
	57,300	" "

It is proposed to have exhibitors furnish drawings of the display they intend making. This will enable the department of electricity to know exactly in what manner the space will be used, and to prevent any oddities or abuses.

I may add that the building is 700 feet long, and 345 feet wide. It contains 185,000 square feet of space. The nave and transept are 114 feet high. Longitudinal galleries extend along each side of the building 115 feet wide, 30 feet above the main floor. At each end these galleries connect with narrower ones. No charge is made for space. The usual regulations govern the placing of exhibits, and any special information can be obtained from the authorities.



TRANSVERSE SECTION OF ELECTRICITY BUILDING.

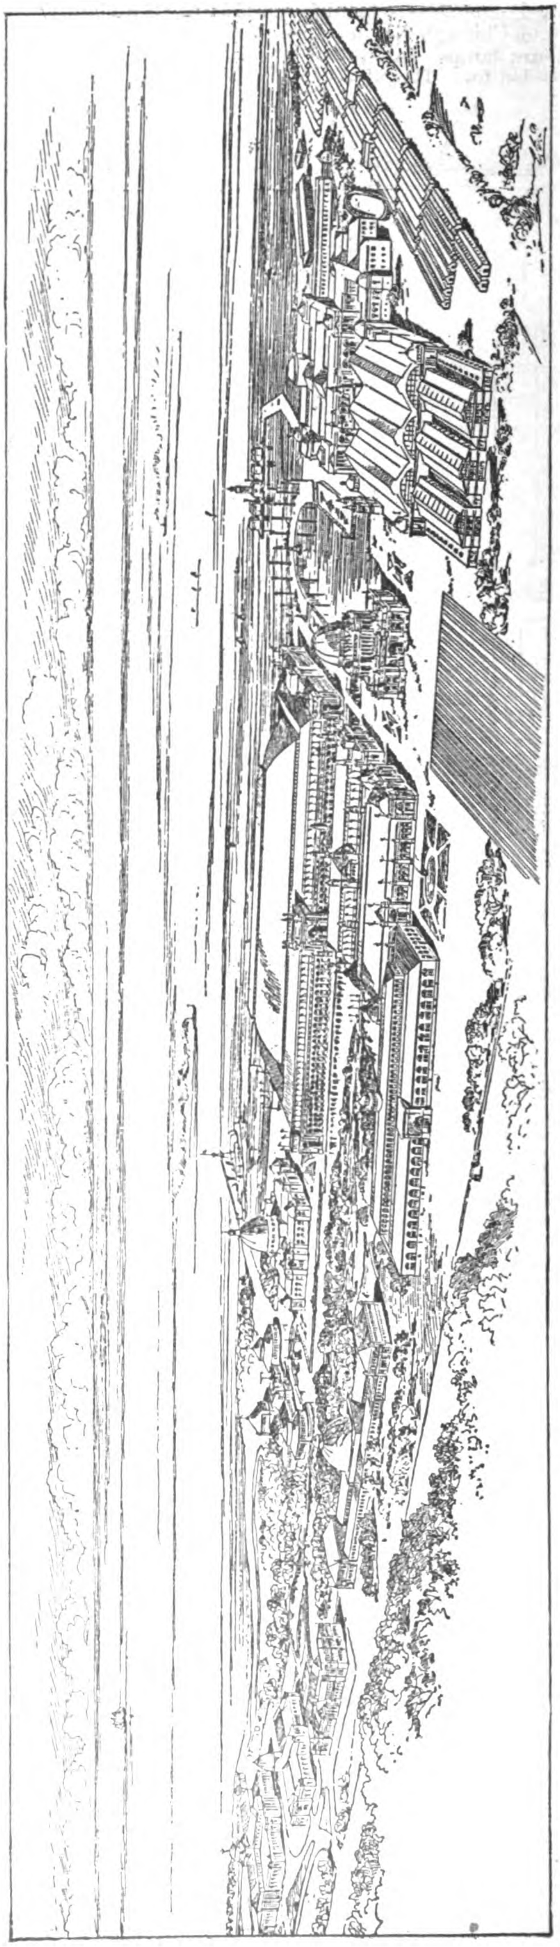
The offices of the Department of Electricity will be placed on the second floor of the Electricity Building and grouped around the hemicycle in the south end, overlooking the Administration Building.

Private rooms will be provided for the chief, assistant chief and the secretary, and apartments for the clerks and stenographers. It is hoped by Prof. Barrett, that they will be able to move into these offices shortly.

It has not yet been determined what space will be assigned to the electrical newspapers, but they will most likely be on the ground floor of the building, where some have expressed their desire to be located.

VII.—GENERATING PLANT.

The main generating plant is to be placed in the Machinery Hall, where a central plant of engines and boilers, arc and incandescent dynamos and electric railway and power generators will be placed, the plant being of a capacity to supply about 100,000 incandescent and from 5,500 to 6,000 arc lamps, and 2,500 h. p. for motors. Several electric traveling cranes will be erected in this building, slowly traversing from one end to the other and arranged for carrying passengers. Many makes of boilers and engines will be installed here, and four large Eddy power generators of 250 k. w. each will be set up. These will be driven by Phœnix engines. Several large Mather and C. & C. generators, driven by Woodbury engines, will also be located here. Sixteen 50-light Brush arc light machines driven by Ball & Wood engines are to furnish current for arc lamps, and the big Westinghouse installation comprises ten alternating current machines, as illustrated recently in THE ELECTRICAL ENGINEER, each of a capacity of 10,000 lights. Four-



BIRD'S EYE VIEW OF THE WORLD'S COLUMBIAN EXHIBITION; LOOKING EAST.

teen Ft. Wayne 50-light machines will be set up, and 20 Standard arc light dynamos, each of 50-light capacity, and 26 Thomson-Houston arc light machines of 50 lights each.

The Westinghouse Co., in addition to their furnishing all the incandescent lights, awarded them by their contract with the World's Fair, are putting in a great many lights for the special illumination of State Buildings, and will do so for exhibitors in cases where the Exposition Co. request it. The charge for this service is $12 per lamp for putting in the wires, lamp and all the work of construction and furnishing current for the same during the entire period of the Fair.

VIII.—ELECTRIC BOATS.

In accordance with the policy of the Fair officials to prevent any smoke nuisance during the exposition, it was determined to use only such boats in the lagoons for carrying passengers from one building to the other by those waterways as would be perfectly clean. While some doubts were expressed as to the feasibility of electric launches in filling the bill, specifications were prepared for them, and every bidder was required to build a boat. A trial of various classes of boats were made. Electric launches were found to do such excellent work that it was determined to use nothing else, and the contract was finally awarded by the Ways and Means Committee of the Exposition Co., acting on the advice of its chairman, Mr. H. N. Higginbotham, for 40 boats to the Electric Launch & Navigation Co. of New York, whose electric launch "Electra" was designed for the company by Mr. Frederick Reckenzaun, the well-known electrical engineer and pioneer electric boat builder of this country.

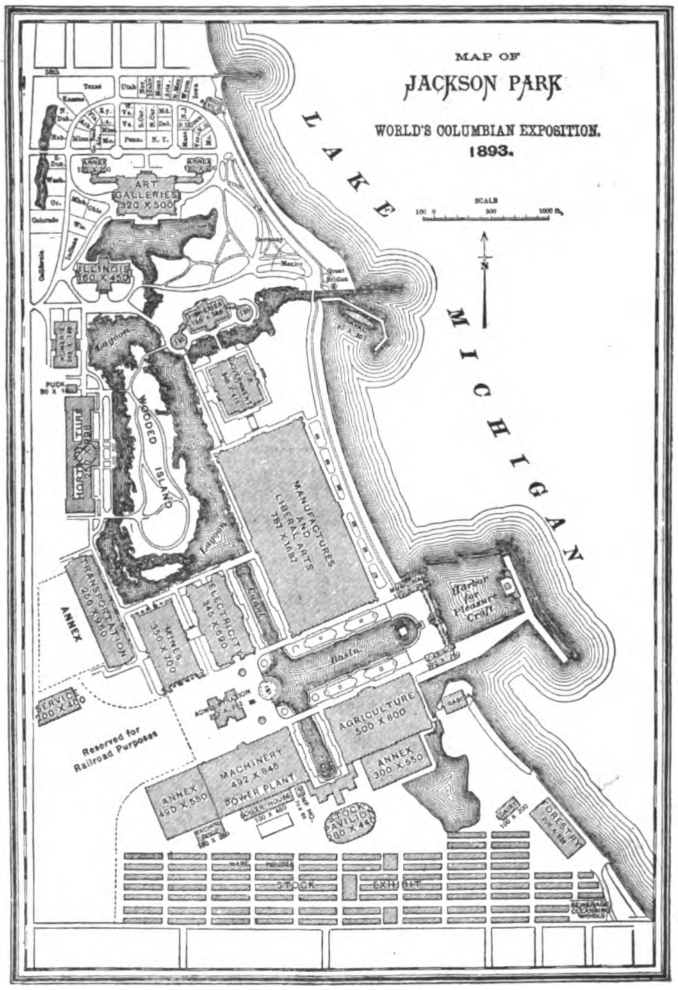
The "Electra" has been very fully described in THE ELECTRICAL ENGINEER, and is a very handsome and beautiful launch. Excellent work was also done during the trial by the electric launch built by the Columbia Launch Co. of Chicago.

IX.—ELECTRIC FOUNTAINS.

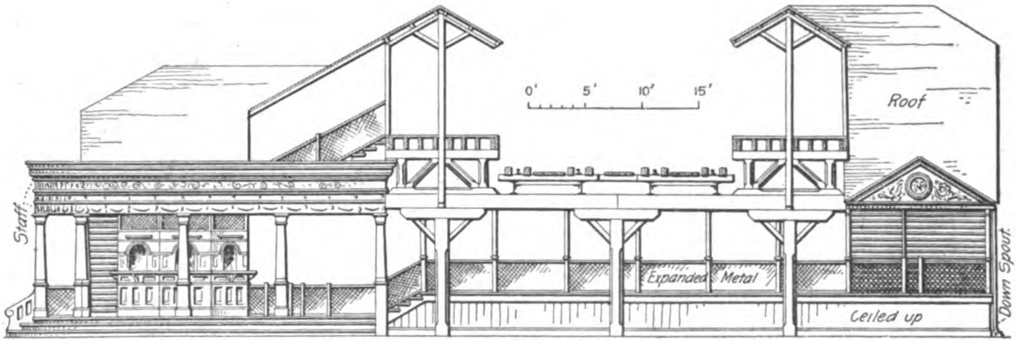
The electric fountains are to be one of the main features of the Exposition, just as electric fountains were at the Paris Exposition in 1889. Those at Chicago are to be of extremely large size, and each one will be supplied by a 24-inch water main. These electric fountains will, it is understood, be two in number, one on each side of the grand McMonnies triumphal fountain, near which the Electricity Building stands, and just adjoining the Administration Building. The work of preparing these fountains has been entrusted most wisely to Mr. Luther Stieringer, the distinguished lighting expert; and it is believed that the result will be very successful. Mr. Stieringer cares little for mere magnitude, but he will aim at producing a harmonious grouping and a beautiful effect.

X.—THE COLUMBIAN INTRAMURAL RAILWAY.

One of the most important features of the Exposition will be the elevated railway which encircles the grounds and will convey thousands of people from one part of the Fair to the other. This, like everything else about the Exposition, is to be operated by electricity, and it will serve as a good illustration to elevated railroad companies of what electric traction can do in such service. The first point about this railway is the power house, which is situated close to the Forestry Building. The main engine-room is 140 feet long by 80 feet wide; the boiler-room is 140 feet long and 50 feet wide; the construction is lumber, with a staff covering, a rear wall of brick and corrugated iron roof. In the boiler-room will be a battery of Babcock & Wilcox boilers aggregating 3,600 h. p. In the engine-room will be one 750 h. p. Allis tandem compound condensing Corliss engine, coupled direct to a 500 k. w. Thomson-Houston multipolar railway generator; one 2,000 h. p. similar Allis engine coupled direct to 1,200 k. w. Thomson-Houston multipolar railway generator; one 750 h. p. vertical Williams engine built by the Lake Erie Engine Works of Buffalo and coupled direct to a 500 k. w. Thomson-Houston multipolar railway generator; one 750 h. p. Greene engine belted direct to 500 k. w. Thomson-Houston multipolar railway generator; one 400 h. p. McIntosh Seymour horizontal tandem compound condensing engine, coupled direct to a 250 k. w. Thomson-Houston multipolar generator. All these machines generate a uniform pressure of 500 volts. The foundations for these engines are built of concrete 3 feet thick, 140 feet long and 50 feet wide, underlaid with 8 inches of timber grillage. The engine-room is so arranged as to be 10 feet above the boiler-room, and in it is placed a gallery for the public to walk around and examine the power house and machinery. A suitable pit on a level with the boiler-room is provided for five condensers and boiler feed pumps, where they are in plain view.



DISPOSITION OF BUILDINGS, WORLD'S COLUMBIAN EXHIBITION.



INTRAMURAL RAILWAY, WORLD'S COLUMBIAN EXHIBITION, CHICAGO.

The rolling stock will consist of 18 trains of three cars each, which will have a speed of from 30 to 35 miles an hour. One motor car will pull two trailers ordinarily, but is fully capable of pulling three or more if required. The motors are 40 feet long with double trucks, and four 100 h. p. single reduction special Thomson-Houston motors will be placed under each car, one on each axle. This will give an exceedingly powerful equipment.

The current for running the motors will be taken from a third rail placed between the other two, by means of a trolley wheel of special construction. It is most probable than an iron T rail fed at frequent points will be used for this purpose, but a copper rod may be installed instead. The structure of the road upon which the cars will run is being built of 12 x 12 posts supported on concrete and frame foundations. Main girders are being madeof 15-inch steel I beams upon which the ties are placed, and a rail weighing 65 lbs. to the yard. The road is a double track one, and will have frequent stations near all the principal buildings. The road is being built by the Western Railroad Dummy Co., of Chicago.

The gentlemen who are supervising and carrying out the work are Mr. C. P. Matlack, chief engineer of elevated structure; R. I. Sloane, consulting engineer of elevated structure; C. H. MacCloskie, electrical engineer; B. J. Arnold, consulting engineer and designer of the power station. Mr. Arnold, who is also the electrical engineer of the General Electric Co., in Chicago, has built some very fine electric railroad stations, notably the one at Little Rock, Ark., which is very novel and judiciously planned.

XI.—CHARGES TO EXHIBITORS.

The World's Fair authorities make a charge to exhibitors of $12 for each 16 c. p. lamp or its equivalent. This sum of $12 covers the cost of wiring, lamp and socket or current supply during the whole period of the Exposition. The $12 consists of a charge of $4 for putting in the light and of the equipments connected therewith, and $8 for the supply of current. As it is expected in the Electricity Building that most exhibitors will install their own lights, they will, in that case, only have to pay $8 for their service.

The charge per horse power for electrical energy will be $20 for ¼ h. p. during the six months of the Exposition, and $60 for 3 h. p. or over; $20 will be a minimum charge, no less amount of power being furnished. The rate for connections from motors to main line will vary from $10 to $15 per horse power in accordance with amount required. The price for arc lamps will be $60 each for the duration of the Exhibition. The rate for steam per horse power is $40 and compressed are $60.

XII.—NOTES ON WIRING.

The New York Insulated Wire Co. made a proposition to the Westinghouse Co. to furnish all wires and cables for the work on which the Westinghouse Co. had secured contracts from the World's Fair authorities. This proposition they accepted with the proviso that their wire should be satisfactory to the Exposition authorities. Grimshaw wires and cables had no trouble in settling this.

The number of incandescent lights in the Administration Building, when completed, will be 4,788 lamps; and in the Art Building, 10,066. These two buildings are nearly completed as regards the wiring. The wire in the two buildings exceeds 500,000 feet in length, and the weight of bare copper is in the neighborhood of 17 tons. The wiring on the various State buildings is progressing very rapidly. The Connecticut, Massachusetts, New Hampshire, New York, Pennsylvania, Wisconsin, Indiana and Iowa buildings are all nearly completed. Work is also being begun on the Photographic Building. The building erected by the White Star Line Steamship Co. and the Colorado Building complete the buildings upon which wiring had been begun when I last looked the ground over.

The wiring for the 5,500 to 6,000 arc lights required for the lamps on the grounds and buildings is pretty well advanced. This work is being done by the World's Fair authorities, several different makes of wire being used. All the wires will be carried in conduits beneath the elevated structure and in the subways. The ducts for the primary incandescent work have all been laid, and a portion of the wire is now been drawn in. Pumplog is used for the conduits which run from the subway, and vitrified sewer pipe under the buildings. More than 300 manholes and as many converter pits are required for the incandescent lighting.

Another item worth adding is that eight electric elevators have been contracted for to go in the Administration Building, and are, I understand, practically ready.

XIII.—THE CLASSIFICATION OF ELECTRICAL EXHIBITS.

I give below the classes into which the electrical exhibits are divided:

DEPARTMENT J.

ELECTRICITY AND ELECTRICAL APPLIANCES.

Group 122.

APPARATUS ILLUSTRATING THE PHENOMENA AND LAWS OF ELECTRICITY AND MAGNETISM.

Class 757. Statical electricity; Class 758. Thermo electricity; thermo-electric batteries; Class 759. Magnets, temporary and permanent; Class 760. Induction coils, converters, etc.

Group 123.

APPARATUS FOR ELECTRICAL MEASUREMENTS.

Class 761. Standard resistance coils; Class 762. Standard condensers; Class 763. Standard batteries; Class 764. Instruments of precision; voltmeters, ammeters, wattmeters, etc.

Group 124.

ELECTRIC BATTERIES, PRIMARY AND SECONDARY.

Group 125.

MACHINES AND APPLIANCES FOR PRODUCING ELECTRICAL CURRENTS BY MECHANICAL POWER—DYNAMICAL ELECTRICITY.

Class 765. Dynamos of direct current, constant electromotive force, varying quantity; Class 766. Dynamos of direct current, constant quantity and varying E. M. F.; Class 767. Dynamos of alternating current, constant E. M. F., and varying quantity; Class 768. Dynamos of alternating current, constant quantity and varying E. M. F.

Group 126.

TRANSMISSION AND REGULATION OF THE ELECTRICAL CURRENT.

Class 769. Cables, wires and insulation; rheostats, switches, indicators, registering meters; ammeters, voltmeters; Class 770. Safety and protective appliances; lightning rods, lightning arresters, insulators, fusible cut-outs, safety switches, etc.; Class 771. Conduits, interior and underground.

Group 127.

ELECTRIC MOTORS.

Class 772. Direct constant current; Class 773. Direct constant E. M. F.; Class 774. Alternating current.

Group 128.

APPLICATION OF ELECTRIC MOTORS.

Class 775. Street, underground, mining and other railways; Class 776. Elevators, pumps, printing presses, and general machinery; Class 777. Toys, novelties, and domestic appliances.

Group 129.

LIGHTING BY ELECTRICITY.

Class 778. The arc systems, their lamps, fixtures, and appliances; Class 779. The incandescent systems, their lamps, fixtures and appliances.

Group 130.

HEATING BY ELECTRICITY.

Class 780. For warming and heating apartments; Class 781. For heating flat irons, soldering irons, and other objects used in industrial operations; Class 782. Maintenance of constant high temperature in ovens; Class 783. Electric heating furnaces.

Group 131.

ELECTRO-METALLURGY AND ELECTRO-CHEMISTRY.

Class 784. Electrotyping; Class 785. Electro-plating, gilding and nickeling; Class 786. Electro-deposition of iron and other metals; Class 787. Electrolytic separation or metals from their ores or alloys.

Group 132.

ELECTRIC FORGING, WELDING, STAMPING, TEMPERING, BRAZING, ETC.

Class 788. Apparatus for, and methods of forging, welding or joining iron, steel and other metals; Class 789. Brazing, stamping, tempering, etc.

Group 133.

ELECTRIC TELEGRAPH AND ELECTRIC SIGNALS.

Class 790. Various systems of transmitting and receiving; Class 791. Chronographs; Class 792. Annunciators; Class 793. Thermostats; Class 794. Fire alarm apparatus; Class 795. Police telegraph and burglar alarm apparatus; Class 796. Railroad signal apparatus.

Group 134.

THE TELEPHONE AND ITS APPLIANCES. PHONOGRAPHS.

Class 797. Cables; construction and underground work; Class 798. Special protective devices; Class 799. Switch boards; Class 800. Transmitting apparatus; Class 801. Receiving apparatus; Class 802. Signalling apparatus; Class 803. Long distance systems; Class 804. Various systems of operation; Class 805. Subscriber's apparatus: Numbers, code, registers, etc.; Class 806. Phonographs. Receiving and recording apparatus; Class 807. Apparatus for the reproduction of recorded sounds and articulate speech.

Group 135.

ELECTRICITY IN SURGERY, DENTISTRY AND THERAPEUTICS.

Class 808. Cautery apparatus; Class 809. Apparatus for the application of the electrical current as a remedial agent — surgical and dental; Class 810. Apparatus for diagnosis; Class 811. Apparatus for the destruction of life.

Group 186.

APPLICATION OF ELECTRICITY IN VARIOUS WAYS NOT HEREINBEORE SPECIFIED.

Class 812. Ignition of explosives; gas lighting, etc.; Class 813. Control of heating apparatus by electricity, as applied to steam and hot air pipes and registers; Class 814. Electric pens; Class 815. Application in photography.

Group 187.

HISTORY AND STATISTICS OF ELECTRICAL INVENTION.

Class 816. Objects illustrating the development of the knowledge of electricity and of the application of electricity in the arts; Class 817. Collections of books and publications upon electricity and its applications.

Group 188.

PROGRESS AND DEVELOPMENT IN ELECTRICAL SCIENCE AND CONSTRUCTION, AS ILLUSTRATED BY MODELS AND DRAWINGS OF VARIOUS COUNTRIES.

Class 818. United States Patent Office and other exhibits of electrical models and drawings; Class 819. Foreign exhibits of electrical models and drawings.

XIV.—THE ELECTRICAL CONGRESS.

In connection with the Exhibition, a great many special Congresses will be held. One of these is the Electrical Congress, of which Dr. Elisha Gray is the chairman. A great deal of work has already been done by Dr. Gray and an Advisory Council, and it is expected that a Congress of 750 to 1,000 delegates will assemble in Chicago next August to establish new units and discuss the leading electrical questions of the day. Active and enthusiastic support is being given Dr. Gray abroad, and in this country he has secured the hearty co-operation of all the electrical societies.

A list of the electrical exhibitors, received as we go to press, will be found on page 509.

MISCELLANEOUS.

OIL VERSUS AIR AS AN INSULATING MEDIUM [1]

BY JAMES BOWSTEAD WILLIAMS, M. D.

THE instruments used in the experiments from which the results about to be set forth in this paper were obtained, were an electrometer, a discharge key, a 6-inch spark coil and a Grenet cell to operate it, and apparatus for holding the oils and other substances while they were being tested.

All of the instruments were illustrated, and the methods of using the same in making comparative tests of insulated wires explained in THE ELECTRICAL ENGINEER of March 30 and April 6, etc., 1892, in a serial by the writer, entitled "Insulated Electric Conductors." With this apparatus, using the same potential as that used in these experiments, the "dielectric after-working" of Boltzman can be demonstrated, if a few inches of a highly insulated wire are tested. The variation of the capacity of a condenser having a small bare wire for its inner coating can also be shown.

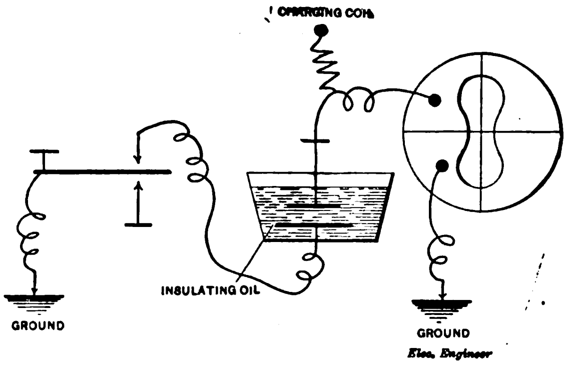


FIG. 1.—WILLIAMS' ARRANGEMENT FOR TESTING INSULATING OILS.

The apparatus in which the oils were first tested consisted of a glass cup to contain the oils and two circular brass discs, parallel to each other, which were immersed in the oil and between which layers of oil could be formed. See Fig. 1.

These discs were each 2⅛ inches in diameter, one of the discs, the lower, being fixed and the other, the upper, movable. The movable disc was soldered to the end of an adjustable screw passing perpendicularly through the centre of the hard rubber cover of the cup, which was 3 inches in diameter.

The method of testing the oils was briefly as follows: The needle of the electrometer, the induction plate, and one pair of quadrants were electrically joined to the frame of the instrument and to earth, and the second pair of quadrants joined to the upper disc.

The lower disc was connected with the binding screw of the upper contact of the discharge key, the lever of the key being depressed and held against the lower contact of the key by the trigger. The lever of the key was joined to earth. Oil was then poured into the cup, sufficient to cover the upper disc when this disk was separated from the lower disc by ⅛ inch, this being about the effective range of the screw.

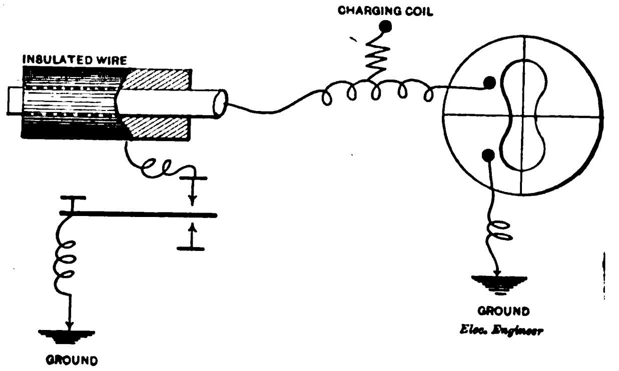

FIG. 2.—WILLIAMS' ARRANGEMENT FOR TESTING INSULATED WIRES.

The quadrants, and of course the upper disc, were then charged by sparks from the coil, to a potential of about 2,800 volts, the illuminating apparatus and scale having previously been adjusted, so that when the quadrants were fully charged the image of the cross-wire would settle at the upper end of the scale, at 300, say.

As the quadrants and discs were absolutely insulated at the potential used, there could be no leakage of the charge as long as the lower disc remained insulated from the earth; but as soon as this disc was connected with the earth, either through the medium of the discharge key or by having its electrode touched with a wire fastened to the gas pipe, leakage would take place through the layer of oil, whatever its thickness might be between the discs; and the rate at which this leakage took place was indicated by the rate at which the image of the cross-wire passed down the scale, *i. e.*, by the rate at which the electrometer was discharged.

The first set of experiments included tests of paraffin and rosin oils, air, and a specimen of a well-known insulated wire. This last test was made to show what took place when the dielectric of insulated wires was tested by means of charges of high potential, and also to make a rough comparison between specific resistance of this dielectric and that of the oils about to be tested. The temperature during the tests was 82° F., and the humidity, as idicated by a Lambrecht's polymeter, 80.

The piece of insulated wire before referred to, about five inches long, was connected with the quadrants and the quadrants charged, see Fig. 2. The edge of a pocket knife blade was then held transversely upon the dielectric, when the image passed rapidly down the scale. This experiment was repeated and the same result obtained. The ends were then paraffined and the specimen again tested. Result almost the same as before paraffining, thus showing that there had been some surface leakage at first. Many of the insulated wires now in use yield the same results when tested exactly as this present sample was tested. But there are also many which give excellent results when thus tested, and there are a few in which there is very little leakage even when several feet are formed into a condenser and tested at this same potential.

By using this method of testing, the superiority of one insulated wire over another, whenever samples a few inches long can be obtained, can easily be demonstrated. It will readily be seen that this fact may become of great importance in legal or other cases in which the comparative insulation resistance of wires is involved. Decisive results can be obtained in many cases from lengths of two or three inches only.

The second set of experiments included tests of five oils, paraffin, wax, ordinary air, and steam. The temperature was 80° F., and the humidity 75.

In this set, the layers of oil were formed between an upper disk nine-sixteenths of an inch in diameter, and a lower disc 1¼ inches in diameter. This lower disc was the flat bottom of a tin box. Its sides were covered with a thick layer of paraffin wax, so that no leakage could take place except through the layers of oil. The discs were absolutely insulated from each other and from earth.

---

[1] Abstract of a paper read at the General Meeting of the American Institute of Electrical Engineers, Chicago, Ill., June 8, 1892.

1. Paraffin oil was first tested in a layer ¼ of an inch thick, but the falling of the image was too rapid to be accurately noted. A layer ⅛ inch thick was then tested and gave a fall of 207 divisions in one minute.

2. Rosin oil tested in a layer ¼ of an inch thick, gave a little better results than the paraffin oil; but when a layer ⅛ inch thick was tested, the fall was 177 divisions in one minute. In these two tests of the two oils all effects due to the drop were eliminated by repeated chargings, so that the fall due to leakage alone was noted.

3. Linseed, cotton-seed and castor oils were each tested in ⅛ inch layers, but as the fall of potential was so much greater than that of the other two oils no further tests were made of them.

Of the three, castor oil had the lowest specific resistance; and there was but little difference between the linseed and the cotton-seed oils, what little difference there was being in favor of the linseed oil.

4. A layer of paraffin one sixteenth of an inch thick and free from air bubbles, was next formed between two tin discs, each 1⅝ inches in diameter, and tested like the layers of oils. When the ground circuit was closed the drop was just five divisions. The quadrants were again fully charged, and the falling of the image noted. This fall was one division in two minutes, or 30 divisions in one hour.

5. A brass tube 10 inches long and five-sixteenths of an inch in diameter was next used for a receptacle for oil. In the centre of this tube was a straight copper wire one-sixteenth of an inch in diameter, the wire being kept concentric with the tube by means of two hard rubber plugs with holes through their centres. The tube contained rosin oil. The wire was connected with the quadrants, and the tube absolutely insulated from the earth and neighboring objects.

The quadrants were then charged and the tube grounded. The image passed down the scale too rapidly to have its rate of falling timed. The hard rubber plugs were carefully paraffined so that all of the leakage took place inside the tube.

A torrent of sparks was poured into the electrometer, but it could not be charged on account of the rapid leakage through the oil.

6. Three plates of glass each 3 by 4 inches and one-eighth of an inch thick, were carefully cleaned and then dried over a lamp. Before they had cooled, one was covered with a film of rosin oil, one with a film of paraffin oil, each film having an area of about two square inches, and the third had a film of paraffin wax about one inch square formed on it. A No. 20 copper wire was fastened to the quadrant electrode, and its free end placed in contact with the centre of the film on the glass. The glass was insulated and the quadrants charged. The image remained stationary as long as the glass was insulated, but as soon as any conducting body, the hand for instance, came in contact with *any* portion of the glass plate, leakage over the film of material on the glass occurred. In each case there was a slight drop, but the quadrants were immediately recharged. The rate of falling of the image with the glass plates covered with the oils was practically the same, the fall being about five divisions to the second; but with the paraffin wax the image remained stationary. Repeated chargings failed to alter the rates of falling of the image.

7. The last tests were made with air and steam, and in both tests the layers were formed with the device used to ascertain the potential of the fully charged quadrants. In the first of these tests, the disks were separated a trifle more than .03 of an inch. The drop in this test was just two divisions, but after that the image did not move in 20 minutes. The writer has made this same kind of test in former years, and has allowed the instruments to stand for hours, and yet there would be no leakage through the layer of air.

The last test was made with a layer of steam of the same thickness as the layer of air in the test just described. The quadrants were fully charged and the ground circuit closed. Steam was then generated in a test tube and the mouth of the tube held directly beneath the discs. This enveloped the disks in steam and also formed a layer of steam between them. As soon as the layer of steam was formed, leakage took place through it, and the leakage increased as moisture was deposited upon the discs (thereby reducing the distance between them) until a bridge of water was formed, when, of course, the quadrants were immediately discharged. From many tests, the writer found that, as nearly as he could determine, the rate of fall, when the layer was composed entirely of steam, was about 20 divisions in one second.

From a careful consideration of the foregoing tests, the results thereof appear to the writer to prove, when continuous high-tension currents *alone* are concerned:

1. That air, even when it has a humidity of 80 per cent., is infinitely superior to oil for insulating conductors carrying such currents. 2. That pure paraffin is far superior to oil, both for insulating conductors and for preventing the escape of the current across the surface of glass. 3. That air having a humidity of 80 per cent. is superior to paraffin as an insulating medium. 4. That oil will not prevent leakage of the current across the surfaces of glass. 5. That whenever oil covers the surface of hard rubber, even when the latter is paraffined, it destroys the high surface insulation of the paraffined hard rubber, that is, the low surface insulation of the oil has been substituted for the higher surface insulation of the hard rubber, when used bare and clean, or when covered with paraffin.

The writer would state that the results of the present tests, which were made in New York City, correspond substantially with results obtained by himself and his brother, Mr. R. W. Welty, while they were making the investigation of insulating material and its applications, which is now being described in the serial before referred to.

A few words relative to the use of the oils in practice, may not be amiss here. To use oil for insulating conductors, there must be an enclosing vessel of iron, or its equivalent, for the oil and conductors. If long tubes are employed for this purpose, two things are indispensable—plugs in the ends of the tubes and means for keeping the wire or cable concentric with the tube, and the individual wires of a cable separated from each other. For the latter purpose, fibrous material is probably the most convenient means. Jute, when pure and dry, is an excellent fibre, both for the oils when used alone and when thickened with rosins, etc., for by reason of the peculiar nature of the fibre, a larger amount of insulating material can be placed within a given space than if a closely-lying vegetable fibre is used; and there will also be fewer points of contact of fibre between the wires and the inside of the tubes. Experiments made by the writer show that there is but little difference in the specific resistance of different kinds of vegetable fibre when the fibre is clean and absolutely dry. The resistance of such fibre is high as long as it remains in this condition. But it is almost impossible to keep it so. It may be a matter of surprise to many to learn that cotton which has been dried, and which therefore possesses good insulating properties, loses these properties in less than 10 minutes if exposed to a damp atmosphere. Whatever means are used for the purpose last above stated, they should have a high specific resistance and allow the use of as much oil as possible.

The plugs must be formed of insulating material which is not injuriously affected by the oils. The best hard rubber, or some special vulcanized rubber or gutta percha compound, appears to be the best for this purpose. Paraffined wood is very apt to be of little use in a short time, owing to its absorptive moisture by capillary attraction.

All oil should be carefully heated, sufficient to expel all moisture and air before it is used. If paraffin oil is used, it is better to subject the oil to a comparatively low temperature and exhaust the air by means of a vacuum than to heat the oil to a high temperature. After the moisture has been removed, the oil must be kept excluded from the air or it will again absorb moisture.

If oil is used as a covering for insulators made of inferior glass or porcelain to be of value it must contain no moisture or dirt; and if used in damp and dusty localities, means must be provided for the self-renewal of the oil, so that fresh surfaces of oil may constantly be exposed. But if insulators had surfaces formed of glass which contained a large proportion of pure silica, better insulation would be effected, if these surfaces were not covered with oil. The writer once found a molded glass vessel, having about the same dimensions and area as the "pony" insulators, which had a surface insulation vastly superior to that of the "pony" insulators. If insulators were made wholly or in part of *such* material a covering of oil would be worse than useless, for experiments have shown that when glass or other material does prevent surface leakage, covering it with oil at once ruins the high surface insulation.

Expansion should be taken into consideration when using these oils in pipes, for if the pipes are full and the oil gets heated, it will expand and probably either expel the plugs or exude at the ends. If it exudes, dust and moisture will collect upon the film of oil and cause surface leakage. This leakage at the ends of pipes containing telephone or telegraph wires, might not be detrimental to the working of the lines, but if the pipes contained wires carrying high-tension currents, serious trouble might arise.

The efficiency of oil to fill holes in dielectrics depends greatly upon circumstances. If the holes or gaps should be formed in the dielectrics of wires conveying weak currents, the oil, if not too sluggish, would have plenty of time to move into and fill such spaces; but if in the dielectrics of wires conveying strong currents, the oil must move very quickly or a disastrous burn-out is the result. And not only this, but the oil, becoming hot expands, and the pipes, if of lead, are apt to be strained or broken by the increased pressure from within, outwards. If the burn-out occurs near the ends of the pipes, the plugs may be expelled. If the filling of spaces were the *only* thing required of the oils, the lighter ones would accomplish this purpose better than the denser ones. But the heavier oils—*e. g.*, heavy and light paraffin oils—are much better for insulating purposes than the lighter.

In conclusion, the writer would state that he feels warranted in believing, unless the contrary can be demonstrated, that dry air, if employed to form a portion of the dielectrics of insulated conductors and if the conditions upon which its highest efficiency depends are fulfilled, is an insulating material superior to oil and even paraffin. Certainly air is cheaper than any other insulating material, and it is not destroyed or injured by intense currents. Burn-outs do not affect it, and if it can be kept dry, which is the great difficulty attending its use, the conductors which it insulates will have a high insulation resistance, and a low electrostatic capacity—two things which are of the greatest importance in electrical engineering.

LETTERS TO THE EDITOR.

THE COMPARATIVE EFFICIENCY OF THE EXTERNAL RESISTANCE AND COMMUTATED FIELD RAILWAY CONTROLLING SWITCHES.

In my "stricture" on Mr. Reid's article on the above subject, it was my intention to simply discuss his argument and not to teach fundamental principles, and as I could see no connection between his "basic" (?) assumption and this argument, I made no comment upon it. For if we follow Mr. Reid, through his juggling of turns and resistances, we bring up at our original speed, with an *increased* field, which surely shows that he had not started (in his argument) with a field equal to the constant, maximum field, which I hope Mr. Reid knows is used with the external resistance, though he now claims to have done so.

That he should claim that I start my argument from a different basis than his own is entirely unwarranted, for we both started from an immediate point. That I did is understood, while that Mr. Reed did is evident from the fact, that having made his changes and regained his former speed, he could certainly by simply weakening his field to its former value increase this speed.

The essential difference between our reasoning was, that I argued for an increase of speed, by both methods pure and simple, while he decreased his speed by a commutated field and then increased it by means of an external resistance, and drew from it a conclusion which fully repaid the experiment. Though by what method he could double his field turns and decrease his resistance I am at a loss to understand.

I can only think that Mr. Reid does not fully understand the inter-relation of speed, field and current in the two methods. And it is somewhat of an imposition upon me and upon the space of this journal that Mr. Ried should ask me to prove that the commutated field varies inversely as the speed and is therefore less intense than the constant maximum external resistance field, except at least speed, and that we should not compare our motors at greatest speed, when the commutated field is weakest, while the external resistance field has remained for all speeds at a constant maximum.

Noting this spirit in Mr. Reid, I beg to refer him to Kapp's "Transmission of Energy," or the "Electric Railway," by Crosby & Bell, for the proofs of what I give him credit for already knowing.

Harold R. Wellman.

WIRING FRAUDS IN NEW YORK CITY.

I noted with considerable interest an article in a recent numcer of your paper in regard to Mr. Low's experience on the Pacific coast with an electric light wireman. It would perhaps be very interesting reading to publish the names in full, and give the buildings in which wiring has been placed in this very city reflecting no very great credit to the so-called electrical engineer that installed the wires.

One case which I can mention exactly corresponds with Mr. Low's experience; that is, a so-called electrical engineer equipped one of the finest residences in this city with electric light wires, presumably using the Grimshaw white core wire. But the underwriters were not such fools as the so-called electrical engineer thought they were, and he had the pleasure of rewiring the building. His method of construction was to place a cheap grade of insulated wire under the floors and in the walls, etc., but wherever the wires were exposed to view, that is, at the various outlets, he very calmly stripped off the cheap insulation, and slipped on pieces of Grimshaw white core insulation. I would advise our mutual friends, the Grimshaw people, to make their white core wire so that it cannot be stripped, and thus made to cover the faults of a cheaper grade of wire.

I trust that your energetic and upright journal, now that this question on dishonest wiring has again been started, will keep the fight up until the architects and owners are made to realize the fact that it requires brains and experience, as well as integrity of character to get good work. It is almost impossible to convince architects that they do not know any more about electric light wires than all the rest of the community put together, and architects are the ones who should he held by the owner of every new building financially responsible for poor electric light equipments.

Insurance Expert.

New York City, Nov. 17, 1892.

ELECTRICITY ON THE FARM.

Your editorial in a recent issue of The Electrical Engineer, on "Electric Motors for the Farm," bears directly upon some work that I did at this college last Spring, an illustrated account of which appeared in the columns of the Engineer, June 1st. As far as I know, this was the first application of the electric motor to *farm work*. This plant has been in successful operation since April 15th, threshing oats, wheat, rye and barley, cutting up silo, grinding up corn, and ginning and pressing cotton.

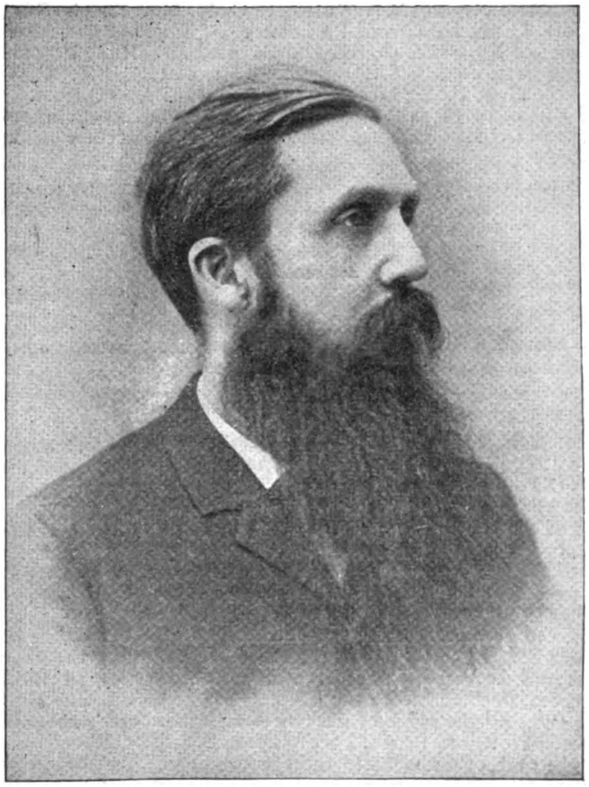
A. F. McKissick.

Alabama Polytechnic Inst., Auburn, Ala.

PERSONAL.

JOHN R. MARKLE.

In the spring of '81, Mr. John R. Markle, then residing in Chicago, made the first out-and-out sale of an isolated incandescent plant to Norton Bros., the owners of the flour mills at the Madison street bridge. This was a small 15-light incandescent machine made by the Edison Co. Previous to this time, Mr. Markle had turned his attention to the question of electric lighting, and having faith from the first in its commercial adaptability, was not afraid to enter into its promotion, although at the time he could hardly have appreciated the difficulties with which, as a pioneer, he was to meet. He then went to Michigan and sold the first plant in the State to a saw mill at Ludington, Mich., this being also a small 15-light machine, the only size at that time manufactured by the Edison Company. In Detroit he put in the first stationary electric motor, to run a shop for shoe manufacturing, and finally succeeded in capitalizing the first central station companies in the West having any considerable investment for low tension direct current constant potential electrical distribution. Since that time Mr. Markle has been continuously connected with the electrical business, and he has now associated himself with the great German company of Siemens & Halske in America, to manage what is known as the central district, comprising the States of Ohio, Michigan, Indiana, Kentucky, Tennessee, North and South Carolina, Florida, Georgia and Alabama, with offices corner Race and 5th streets, Cincinnati, Ohio. With him is Mr. Harnish, late president of the Peninsular Electric Co., of Grand Rapids.



John R. Markle.

MARRIED.

GRAHAM—PHELPS.

HELEN LAPHAM PHELPS, daughter of Mr. and Mrs. George M. Phelps, was married at her parents' house in Brooklyn, N. Y., November 17, 1892, to George Wallace Graham, of Minneapolis, Minn. The ceremony was conducted by the Rev. Stephen H. Camp, of the Third Unitarian Church, at 12 o'clock, in the presence of the immediate families and near relations, and three girlhood friends of the bride.

After the marriage a wedding breakfast and reception were held from 12:30 till 2 o'clock p. m., during which many friends came to offer their congratulations. During the wedding and reception delightful music was played by a detachment of Anton Seidl's orchestra of four stringed instruments headed by Mr. John Cheshire with his harp. Everything was of the most informal and unconventional character. There were no bridesmaids nor best man, the bride being attended by her father and mother only. The ushers for the reception were: William L. Fort, George Phelps Fort and Harvey Crissey, all cousins of the bride. Among the wedding guests and those present at the reception were: Dr. and Mrs. Schuyler S. Wheeler, Miss Virginia Fitz-Randolph, Mr. and Mrs. T. Commerford Martin, Mr. Joseph Wetzler and Mr. George Barton Muldaur, of New York; Mr. and Mrs. Oscar Pfeiffer, Mr. and Mrs. James Young, Mrs. Caleb Shepard, and Mr. Fredrick O. Pierce of Brooklyn, N.Y.; Mr. and Mrs. C. Stoddard, Mr. and Mrs. Walworth Cady, Miss Phoebe Stoddard and Mrs. Laura Hewitt, of Plattsburg, N. Y.; Rev. and Mrs. Olin Hallock, of Norwalk, Conn., and Dr. and Mrs. R. F. Benson, Jr., Mr. and Mrs. Joseph A. Powers and Mr. and Mrs. M. M. Waterman, of Troy, N. Y.; Mr. A. C. Shaw, of Boston, Mass. Soon after the close of the reception Mr. and Mrs. Graham started westward for Minneapolis, where they will make their home.

LEGAL NOTES.

THE EDISON—SAWYER-MAN CASE.

EDISON ELECTRIC LIGHT COMPANY AND EDISON GENERAL ELECTRIC CO. *vs.* SAWYER-MAN ELECTRIC CO.

Defense of the Sawyer-Man Company.

THIS case, adjourned November 4–11, 1891, came up for hearing before Judge Lacombe, Friday, November 18, 1891, in the United States Circuit Court, on a motion for a preliminary injunction.

The allegation that the complainants are a monopoly, in violation of the Sherman Anti-Trust Law, was the defense offered. Clarence A. Seward, Grosvenor P. Lowrey and R. N. Dyer are counsel for the Edison interests, and Edmund Wetmore, Elihu Root and Leonard E. Curtis for the Sawyer-Man Company, which supplies the Westinghouse Company with lamps.

Mr. Curtis, in arguing for his side, resisted the granting of any injunction on the ground that the complainants are violating the Anti-Trust Law. He read an affidavit from George Westinghouse, Jr., declaring that the General Electric Company substantially owns all the stock of the two complainant companies, of the Thomson-Houston, Brush, Fort Wayne, Schuyler, Excelsior, Van Depoele and other electric light companies. The affidavit declares that the General Company is trying to get a monopoly of the whole business of electric lighting, and, on the strength of the Court of Appeals decision, is trying to prevent the Westinghouse Company from making and selling dynamos. The decision applies only to lamps. Mr. Westinghouse said that the General Company people told the World's Fair directors that his company could not supply lamps, so that it might not get the contract to light the buildings.

Mr. Westinghouse says he has invented a lamp which does not infringe the Edison patent. By January 1 he will be able to manufacture it in sufficient quantities to supply his trade.

Upon the opening of Court Saturday, November 10, Judge Lacombe stated to counsel that his time was very fully taken up in the near future by other causes, that he would not be likely to reach a decision in this case at a very early date, and in view of the importance of the question at issue and the magnitude of the interests involved suggested that the suit be referred to the U. S. Appelate Court which would convene in this city, December 6.

His Honor's suggestions was accepted by counsel for both sides and an order was agreed to accordingly. The agreement included the issue of a preliminary injunction and a stay of the same till the session of the Appelate court, December 6, and a further stay from that date provided the defense be then ready to proceed with the argument of the case. This disposition of the suit leaves the whole matter in *statu quo* until December 6.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED NOVEMBER 8, 1892.

Alarms and Signals :—

Electric Railway Signal, A. J. Wilson, Port Chester, N. Y., 485,728. Filed Feb. 29, 1892.

An automatic block signal for steam railways.

Thermostat and Alarm, G. Fischer, Chemnitz, Germany, 485,739. Filed July 20, 1892.

Claim 1 follows :

In a fire-alarm, a flat spring held, against its normal tendency, in a strained position by a hard coating or sheet of gelatine.

Railway Signal Apparatus and System, J. W. Lattig, Easton, Pa., 486,047. Filed Aug. 18, 1892.

An automatic electric lock signal for steam railways.

Water Indicator for Boilers, W. H. Rodgers, Bay Side, N. Y.. 485,054. Filed May 21, 1892.

Distribution :—

Electric Transmission of Power, E. W. Rice, Jr., Lynn, Mass., 485,658. Filed Sept. 18, 1891.

Comprises at both generating and receiving stations direct and alternating current machines, the receiving station having its machines mechanically connected and having a connection seperable from the current mains and leading from the direct current machine to the field of the alternator.

Electric Transmission of Power, E. W. Rice, Jr., Lynn, Mass., 485,659. Filed Sept. 18, 1891.

Invention consists in causing a single direct current alternating machine to first act as a motor, to start the main motor, and then as a generator driven by the main motor, and feeding the field currents thereof.

Dynamos and Motors :—

Design, 21,981, *Electric Motor Frame*, B. D. Southard, Chicago, Ill. Filed June 20, 1892.

Lamps and Appurtenances :—

Manufacture of Carbon Filaments, T. A. Edison, Llewellyn Park, N. J., 485,615. Filed Dec. 15, 1886.

Manufacture of Carbon Filaments, T. A. Edison, Llewellyn Park, N. J., 485,616. Filed Dec. 15, 1886.

Employs carbonized asphaltine for the filament.

Incandescent Lamp Filament, T. A. Edison, Llewellyn Park, N. J., 485,617. Filed July 17, 1888.

The method of making carbon filaments from asphalts or hydrocarbon residues.

System of Lighting Railway Cars and Platforms, D. B. Nichols and C. L. and C. A. Cotton, Dedham, Mass., 485,647. Filed Sept. 7, 1891.

Employs a lamp at each end of the car both on the same side, a switch for each lamp and reflectors arranged to distribute the light along the steps and side of the car.

Incandescent Electric Lamp, A. C. Carey, Lake Pleasant, Mass., 485,682. Filed June 15, 1892.

Employs couplings for the leading-in wires and filaments composed of tubes constructed between their ends and applied to the ends of the wire by crimping.

Electric Arc Lamp, G. Kirkegaard, Brooklyn, N. Y., 485,744. Filed May 13, 1892.

Employs a train of wheels for feeding the carbon and an escapement wheel mounted in a separate stationary frame, pivoted concentrically with the escapement wheel so that the centre of gravity of the latter will remain constant while that of the frame is shifted.

Electric Arc Lamp, J. R. Steers, New York, 485,895. Filed May 28, 1892.

Has for its object to simplify the construction and arrangement of focusing lamps.

Measurement :—

Voltmeter, E. R. Carichoff, Richmond, Ky., 485,896. Filed May 12, 1890.

Makes use of the heating instead of the magnetic action of an electric current so that the elevation of temperature is measured by expansion.

Metal Working :—

Electric Forge, G. D. Burton, Boston, Mass., and E. E. Angell, Somerville Mass., 486,029. Filed Dec. 22, 1891.

An electric forge in which the electrodes for supporting the bars to be heated may be readily adjusted for different lengths and thicknesses of metal.

Miscellaneous:—

Apparatus for and Process of Refining Copper by Electricity, F. Farrel, Ansonia, Conn., 485,618. Filed April 26. 1892.

Rheostatic Controller for Electric Motors, J. P. B. Fiske, Lynn, Mass., 485,619. Filed Feb. 5, 1892.

A rheostatic controller having a rheostat connected to the armature of a shunt-wound motor, a short circuit connected to the field magnet and containing a circuit breaker and a circuit reverser in the field magnet connections.

Electric Motor Controller, J. P. B. Fiske, Lynn, Mass., 485,620. Filed Feb. 5, 1892.

Employs a permanently closed continuous circuit including in series the resistance and the field magnet and armature of the motor, and a rheostatic switch connected with the resistance and motor.

Electric Clock, J. D. McAnglis and H. E. Fleming, Beaver Falls, Pa., 485,645. Filed June 7, 1892.

Continuous Current Transformer, E. Thomson, Swampscott, Mass., 485,669. Filed Aug. 28, 1891.

Comprises a rotary transformer having an armature whose winding is connected through commutating devices to the circuit, and a secondary winding connected to independent commutating devices, and additional commutating devices rotatable relatively to the aforesaid commutating devices, and connected with a separate circuit and with a secondary winding.

Electric Belt, E. N. Tefft, Iola, Kans., 485,754. Filed July, 30, 1892.

Electric Perforation Pen, A. D. Lewis, Canton, Mo., 485,767. Filed June 30, 1892.

Method of Magnetically Separating Ores, T. A. Edison, Llewellyn Park, N. J., 485,841. Filed July 20, 1892.

Has for its object to eliminate the sulphur from concentrated iron ores where the original ore contains magnetic pyrites.

Method of Magnetic Ore Separation, T. A. Edison, Llewellyn Park, N. J. 485,842. Filed July 20, 1892.

Designed for the treatment of low-grade nickeliferous pyrites ores to recover the nickel therefrom and also the cobalt, gold, copper, and other metals that may be present.

Manufacture of Mandrels for Electrolytic Deposit of Tubes, F. E. Elmore, Leeds, 485,919. Filed Aug. 12, 1891.

Automatic Electric Scale, P. J. Kohbacher, Ashland, Ky., 485,950. Filed Mar. 24, 1892.

Railways and Appliances :—

Electric Railway Switch, C. A. Stone and E. S. Webster, Boston, Mass., 485,668. Filed Oct. 30, 1890.

Has for its object to control the track switches directly from the moving car, by means of a supplemental trolley and overhead conductor.

Switches and Cut-Outs :—

Switchboard for Electric Light Circuits, J. J. Moore and D. A. Henry, 485,643. Filed April 9, 1890.

Invention consists in providing two sets of wires at right angles to each other, one set connected to the dynamos and the other to the circuits, each set being provided with contact devices placed opposite to similar devices in the other set.

Telegraphs:—

Telegraph Sounder, J. Maret, Mt. Vernon, Ky., and W. L. De Graff, Homer, Mich., 486,051. Filed Aug. 4, 1891.

Telephones and Apparatus :—

Telephony, W. Bruening, East Orange, N. J., 485,859. Filed Aug. 1, 1891.

Employs a receiver, consisting of a closed hollow vessel containing a fluid and provided with dashers in movable contact with the fluid, one provided with a spring and each of the others with a diaphragm.

Telephone, J. W. McDonough, New York, 485,876. Filed July 21, 1884.

Employs a vibratory body having electrical conductors arranged parallel to one another over its whole surface; the conductors being vibratory and imparting their action to the body.

ELECTRICAL EXHIBITORS AT THE WORLD'S FAIR.

FOLLOWING is a list of those whose applications for space in the Electricity Building at the Columbian Exhibition have been granted: [See article on "Electricity at the World's Fair.]

Amateur Electrician; American Bell Telephone Co.; Anthony Elec. Instrument Co.; Arnold Elec. Mfg. Co.; American Exhibition Co.; American Graphophone Co.; Adler, Leon D.; Akron Elec. Mfg. Co.; American Tanning Co.

Bain Elec. Mfg. Co.; Brooks, R. T.; Brooks, John C.; Brush Elec. Co.; Bryan, Enholm & Co.; Billings & Spencer Co.; Belknap Motor Co.; Bottome, Turner D.; Berliner, E.; Brady, T. H.; Barton Bell Co.; Blodgett Mfg. Co.; Butler Hard Rubber Co.; Beacon Vacuum Pump & Elec. Co.

C. & C. Elec. Motor Co.; Cutter, George; Crocker-Wheeler, Elec. Co.; Consolidated Elec. Storage Co.; Commercial Cable Co.; Cook, Victor A.; Cobb Elec. Wire Co., of Wilmington, Delaware; Chicago Society of Operative Electricians; Chicago Magnetic Shield Co.; Commercial Elec. Co.; Columbia Incandescent Lamp Co.; Central Elec. Co.; Cross, Frank; Cregier, DeWitt C., Jr.

Davy Elec. Belt & Appliance Co.; Duplex Elec. Co.; Dayton Fan & Motor Co.; Devey, Matthew H.; Du Laney Clock Co.; Detroit Elec. Works; Day, S. A.; Delaware Hard Fibre Co.

Elec. Merchandise Co.; Electrical Supply Co.; *Electrical World;* Eureka Elec. Co.; Elgin Telephone Co.; Empire Gold & Silver Plating Works; Engineering Equipment Co.; Eureka Tempered Copper Co.; Electrical Industries Pub. Co.; Edgerton, N. H.; Electric Gas Lighting Co.; Electrical Forging Co.; ELECTRICAL ENGINEER; *Electrical Review;* Electricity Newspaper Co.; Electric Secret Service Co.; Electric Eng. & Supply Co.; Elec. Heat Alarm Co.; Eddy. Elec. Mfg. Co.; Elec. Advertising & Display Mfg. Co.; Elec. Machine Co.; Elec. Appliance Co.; Excelsior Elec. Co.; Egan, Chas. E.; Empire China Works; Electrical Age Publishing Co.; Electro-Medical Battery Co.; Edgerton, E. M.; Electrolibration Co.; Edison, Thos. A.

Field Engineering Co.; Fibre Pipe Co.; Ft. Wayne Elec. Co.; Ford-Washburn Storelectro Co.; Franklin Elec. Appliance Co.; French, H. W. & John Warren.

Guillaume, Alfred; Gray, Elisha; Greeley, The E. S. & Co.; Goodwin, F. O.; General Electric Co.; Gamewell Fire Alarm Tel. Co.; Germania Elec. Co.; Great Western Elec. Supply Co.

Hanson & Van Winkle Elec. Co.; Heisler Elec. Co.; Hirlimann, Chas. J.; Hornell Iron Works; Hall, Chas. Fred.; Huestis, Chas. D. C.; Holmes, Nathaniel L.; Houlehan, James; Hope, Elec. Appliance Co.

Interior Conduit & Insulation Co.; India Rubber Comb Co; International Elec. Ry. Co.; Illinois Alloy Co.; Indiana Insulated Wire & Rubber Co.

Jenney Elec. Motor Co.; H. W. Johns Mfg. Co.; Johnson Elec. Co.

Kirwin Elec. Indicator Co.; K. A. P. Elec. Novelty Co.

Lang, J. & Co.; La Roche Elec. Works; Le Clanché Battery Co.; Leatheroid Mfg. Co.

C. McIntire Co.; Munson Lightning Conductor Co.; Marcus, Wm. N.; Moore, Alfred F.; Mather Elec. Co.; Mather, A. C.; Munson Belting Co.; Municipal Fire & Police Tel.; Mason, Jas. H.; McCaskey, Alfred S., & J. A. Ellis; Manhattan Elec. Supply Co.

New York Insulated Wire Co.; National Elec. Mfg. Co.; Newman Clock Mfg. Co.; Norwich Insulated Wire Co.; New England Butt Co.; North American Elec. Co.; New York & London Elec. Ass'n.; National Carbon Co.

Owen, Dr. A.

Perkins, Frank C.; Paiste, H. T.; Page Belting Co.; Pumpelly, Jas. K.; Pennock Battery, Elec. Light & Improvement Co.; Perkins Elec. Lamp Co.; Phœnix Glass Co.; Praul Rotary Steam Engine Co.; Phelps, A. H., M. D.; Wm. Powell Co.; Perry & Runlett; Pulvermacher Galvanic Co.; Pratt Electro Medical Supply Co.

Quin, J. B.; Quinby, Wm. C.; Queen & Co., Jas. W.

Railway Equipment Co.; Ravell, Alex.; Rich. Elec. Heating Co.; Rogers, J. Harris; Ries Elec. Specialty Co.; Roessler & Hasslacher Chemical Co.; Rauscher, John; Robinson Machine Co; Ringler, F. A. Co.; Riker Elec. Motor Co.; Ries, Elias E.; Rosseau's Elec. Works.

Sperry Elec. Mining Machine Co.; Standard Underground Cable Co.; Sponholz, Carl L.; Short Elec. Ry. Co.; Swan Lamp Mfg. Co.; Standard Paint Co.; Striemer, A.; Siegler, Jas. O.; Steward Mfg. Co., The D. M. Strowger Automatic Telephone Exchange; Sample, H. C.; Sarony, H. J.; Stanley Elec. Mfg. Co.; Schieren, Chas. A. & Co.; Standard Elec. Signal Co.; Standard Battery Co.; Sanden Elec Co.; Stoelting, Christ. H.

Thermo. Elec. Heat Regulating Co.; Thomson-Houston Elec. Co.; Ticonderoga Machine Co.; Thomson Elec. Welding Co.; Todd, John T.; Thompson & Robertson; Tompkins, Mrs. Jennie E.; Tropical American Tel. Co.; Tate.

Utica Elec. Mfg. and Supply Co.; Union Elec. Works.

Vetter, J. C. & Co.; Vail, Stephen; Viaduct Mfg. Co.

Western Elec. Co.; Weston, Wm. H. & Co.; Writing Tel. C.; Washburn & Moen Mfg. Co.; Waterhouse Bros.; Western Electrician; Weston Elec. Instrument Co.; Westinghouse Elec. & Mfg. Co.; Western Union Tel. Co.; Wing, L. J.; Waddel-Entz Co.; Webb, Dr. G. F.; Wiesinfeld, Robt. S.; Woods, Granville T.

Zucker & Levett Chemical Co.

NEW ISSUE OF GENERAL ELECTRIC BONDS.

A DISPATCH from Boston of Nov. 15 says:—The General Electric Company will issue a circular offering common shareholders the right to subscribe for $6,000,000 additional 5 per cent. bonds at par, making the total issue $10,000,000. There is $30,067,200 common stock, and the allotment will be in the ratio of one in five. The outstanding bonds sold last week at 104 and are now 102, so that not much value attaches to the right. The issue has been underwritten for a small commission, which is a practical gratuity to the underwriters, as the bonds would naturally sell themselves. It is announced that the proceeds are required for working capital.

SOCIETY AND CLUB NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

AT the monthly meeting of council, held November 15th, the following associate members were elected:

Arnold, Craig R., electrician and treasurer, Arnold Electric Mfg. Company, Chester, Penn.

Bohm, Ludwig K., Ph.D., consulting electrical and chemical expert, 81 Nassau street, New York City.

Durant, Edward, electrician with F. Pearce, 115 East 26th street, New York City.

Gale, Horace B., consulting electrical and mechanical engineer, 40 California street, San Franciso, Cal.

Hunting, Fred S., electrical engineer, Fort Wayne Electric Company, Fort Wayne, Ind.

McElroy, James F., mechanical superintendent, the Consolidated Car Heating Company, 131 Lake avenue, Albany, N. Y.

Stahl, Th., Creusot Works, Creusot, France.

The following associate members were transferred to full membership, their applications having been approved by the Board of Examiners:

Bourne, Frank, electrical engineer, Field Engineering Company, 143 Liberty street, New York City.

Thomas, Benjamin F., professor of physics, Ohio State University, Columbus, Ohio.

Wurts, Alexander J., electrical expert, Westinghouse Electric & Mfg. Company, Pittsburg, Pa.

Metcalfe, George R., electrical engineer, editor, *Electricity*, New York City.

Stillwell, Lewis B., electrical engineer, Westinghouse Electric & Mfg. Company, Pittsburg, Pa.

At the meeting of the institute in the evening, Dr. J. B. Williams made a series of tests of the insulating qualities of different oils, referred to in his paper read at the Chicago meeting of the institute. The insulation of samples of various wires was also tested, and the use of his apparatus was fully explained. Dr. Williams had an electrometer mounted on the lecture table, and the spot of light was reflected on a scale pinned to the wall. The members were thus able to follow his demonstrations very closely.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

A good advertisement keeps off wrinkles, and is better than a hair restorer.

THE PENNSYLVANIA ELECTRIC ENGINEERING CO.

The excellent and thorough work done by the Pennsylvania Electric Engineering Co., of Philadelphia, has naturally resulted in the acquisition of large contracts throughout the country. One of the most recent of these is in the new Philadelphia & Reading Railroad terminal depot in Philadelphia and consists of a lighting plant comprising 300 Western Electric arc lights, 10 Western Electric dynamos and the entire construction work.

The company has issued a handsome lithograph of the depot, which is said to be not only the finest building of its kind in the world, but one of the most handsome public buildings in America. The building occupies four city squares, is fireproof and cost, together with the elevated tracks, upward of ten million dollars.

MR. PAUL T. KENNY.

The representation of Mather dynamos and motors was recently taken in this vicinity by Mr. Paul T. Kenny, who has been in the field as an electrical contractor and engineer for some time, and who now has his offices in the Bennett Building, Nassau St., this city. Mr. Kenny reports having sold the *New York Herald*, for its new building on Broadway and West Thirty-fifth street, four Mather generators of 450 amperes each; one 40 h. p. Mather motor and two of 20 h. p. each. This apparatus is to be delivered by January 1. Four other recent contracts secured by Mr. Kenny are a 1 h. p. motor for J. B. Hecker, optician, Brooklyn; a 3 h. p. motor for T. F. Larkin, printer, Brooklyn; a 15 h. p. for the Jennings Lace Works, Brooklyn; and a 10 h. p. to C. H. Jones & Co., printers, New York City. Mr. Kenny sees plenty of good business ahead.

THE JENNEY ELECTRIC MOTOR COMPANY.

The well-known Jenney Electric Motor Company, of Indianapolis, Ind., are complaining that orders will persist in coming in so rapidly that the demand exceeds the supply, and they are under the painful necessity of enlarging the works and increasing facilities. Their "Constant Pressure" power generators are meeting with high favor, as are also their lighting and plating dynamos. The company are also contractors for complete light and power plants.

WESTERN NOTES.

New York Insulated Wire Co.—In the office of the New York Insulated Wire Co., at No. 80 Franklin street, Chicago, is in operation one of the most novel electric lighting plants in the country. The current is furnished by a dynamo, driven by an arc circuit motor, both installed by Mr. Chas. E. Gregory, the well-known dealer in dynamos, motors, etc., and the wires are encased in Vulca ducts from the dynamo to the lamp, the circuits being laid out so as to show a complete distributing system of Grimshaw white core wire in Vulca duct, with all the necessary appliances in the way of junction boxes, fishing boxes, elbows, etc., and any wire can be disconnected and taken out from the lamp to the switchboard. Among the novelties used in the construction of the plant are the Electric Engineering and Supply Co.'s sockets, switches, etc., the Cutter Electric Mfg. Co.'s flexible brackets, and the Sunbeam incandescent lamps. Mr. Geo. H. Meeker cordially invites all who are interested, especially architects, to inspect this model plant. A constant source of attraction is an illuminated picture of the grounds and buildings of the World's Columbian Exposition, showing Grimshaw white core wire in Vulca ducts, lighting all the incandescent lamps. Every architect or electrician should inspect this plant, as it is an exceedingly interesting one.

Messrs. A. M. Morse & Co., contracting engineers, Commercial Building, St. Louis, Mo., have closed contracts during the past month for a number of Buckeye engines, boilers and complete power outfits for central stations, and isolated plants at Monticello, Ind., Spring Valley, Ill., Fulton, Mo., Springfield, Mo. and Kansas City, Mo.

J. Lang & Co., 44 Michigan street, Chicago, are in receipt of numerous orders for their Lang and Andrew switches, which have a high reputation and are prime favorites among electrical people for carrying heavy currents. They use the best material in their construction and the workmanship is also most excellent.

The Railway Equipment Co., Pullman Building, Chicago, have just closed two extensive contracts with the Cincinnati Street Railway Co., and the Cincinnati & Covington Street Railway Co. for overhead supplies, line material, etc. These contracts were secured in the face of keen competition and are both for a very large amount of material. The volume of electric railway supply business being handled by this company is exceedingly extensive, and the quantity of goods being shipped every day from their store is an impressive sight.

The Electric Appliance Company have just closed arrangements with the Whitney Electrical Instrument Company, of Boston, to handle their celebrated line of test instruments in the West. The Whitney has already established a reputation for accuracy and ability to stand rough usage wherever it has been in use. It is also particularly neat in appearance. The Electric Appliance Company will carry a large and complete stock, and push them extensively in the West.

The Chicago Electric Manufacturing Co., 73–75 West Jackson street, Chicago, are very busy and doing a good business. They manufacture a fine line of electric and combination fixtures and also electrical apparatus of various kinds and do all sorts of electrical work. Since Mr. E. R. Crolius assumed the management of the company, their business has largely increased.

The Osborne Steam Engineering Co., 167 Dearborn street, are building several power plants for electric work. They have now in the course of construction the plant for the Pabst Heat, Light & Power Co., of Milwaukee, which is of 2,000 h. p. capacity. Mr. Osborne, engineer of the company, has carried out a large number of important power and heating contracts.

Mr. Osgood, agent for the Premier Steel Co., of Indianapolis, Ind., is now settled down in his new quarters in the Manhattan Building, Chicago, and is busy introducing their new electric elevators for which many novel and advantageous features are claimed; and also taking contracts for the well-known hydraulic elevators manufactured by this company.

Mr. Edw. R. Grier, 1522 Monadnock Building, Chicago, is agent for the new switch manufactured by Russell & Officer, of Denver, Colo., enabling the lights to be controlled from any one or any number of points. It can also be used for controlling current from any distant point for any electrical translating device such as a motor, lamp, etc.

The Bain Electric Manufacturing Co, 47 South Jefferson street, Chicago, have their shop full of orders for dynamos, motors and mining machinery. They are making quite a specialty of electrical machinery for mines and are constructing some fine electric locomotives for this purpose.

The Mosher Arc Lamp and Manufacturing Co., of 127 Ontario street, Chicago, are enjoying a brisk run of trade on their Mosher arc lamps for constant potential circuits, both direct and alternating. Present auguries tend to show that they will do an immense business with their new alternating lamp.

Rattenburg & Jones, electrical contractors. 435 Rookery Building, Chicago, are doing a general contracting business installing electric lighting plants complete, electric bells, gas lighting and burglar alarms. They also deal in fixtures.

Mr. Geo. McKinlock, of the Central Electric Co., Chicago, spent a very pleasant time while abroad this summer. He visited Ireland, Scotland, England and Paris and made some interesting inspections of electrical work during his trip.

The Chicago Incandescent Lamp Co., No. 75 Clinton street, manufacturers of the Pray incandescent lamp, have received some reports of recent tests of their lamps which speak very highly for their durability and efficiency.

Geo. Meeker, Chicago manager of the New York Insulated Wire Co., says that his business is continually on the increase and Grimshaw wires and cables are holding their own in a very gratifying manner.

The Great Western Electric Supply Co., South Canal street, Chicago, report their sales for the last month as exceedingly heavy, and the demand for their specialties particularly good.

Mr. A. S. Terry, of the Sunbeam Incandescent Lamp Co., Chamber of Commerce Building, Chicago, says business is good and the demand for Sunbeams fully up to his expectations.

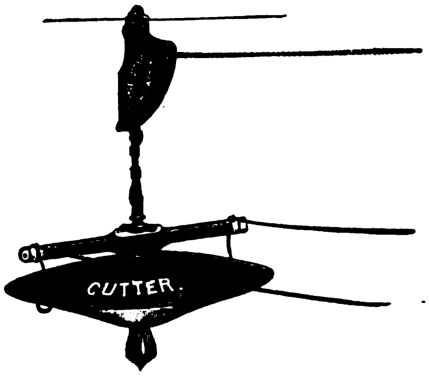
Mr. R. E. Gallaher, secretary of the New York Insulated Wire Co. spent a week or so recently in Chicago.

The Telegraphers' Mutual Benefit Association, at its annual meeting last week, reported a very successful year, and President Merrihew congratulated the members on the great good work done by the society during its 25 years of existence; $1,000 was appropriated to push the membership this year. The old officers were re-elected. In the evening the Magnetic Club gave a very successful dinner.

CUTTER'S SUSPENSION STREET HOOD.

Street lighting with incandescent lamps is getting to be quite a common practice in all parts of the country, and in many places the lamps are hung over the centre of the street. This plan is considered the best on shady streets where the foliage would cut off much of the light from a lamp placed at the corner. Then in order to get a proper distribution of the light it is necessary to have a specially designed reflector, which can be combined with the protecting hood. In many cases the hoods, hooks and pulleys used have been picked at random from the nearest stock, the result being a combination which neither looks neat nor is well adapted to the purpose.

After studying the needs in this line for some years, George Cutter has perfected the suspension street hood shown in the cut. It embodies a number of novel features. The hood is designed so as to protect the socket thoroughly from the weather, while a unique spring-catch and hinge allows it to be opened when desired. The nozzle which supports the socket is arched, so that it can be readily wired, and the tin parts are separable so that they can be nested for shipment. Another patented feature is the method of clamping the parts of the crossarm, whereby the hood itself is insulated from the suspending cable. The pulley used with this hood is known as "Cutter's Petite" and is a small size of the lamp-supporting pulley designed for arc lamp practice, holding the hood safely even if the hoisting rope should slip.



Cutter's Suspension Street Hood.

The same suspension outfit is also used by some plants on alternating circuits with the transformer hung just above the hood, and in all cases it makes a neat and very serviceable combination. George Cutter, of Chicago, is the patentee and sole maker.

A DESIRABLE AND PRAISEWORTHY APPOINTMENT.

Mr. J. E. Ham, who has for some years held the position of chief clerk, and, as well, for a portion of the time, managed the business of the New York office of the Kerite Co., has been appointed general agent with headquarters at New York, by Mr. W. R. Brixey, who has succeeded to the entire wire business of the late A. G. and S. A. Day, respectively. Mr. Ham is one of those young men who by strict attention to business and by sterling business qualities has reaped a portion of the reward commensurate therewith. The acquisition is a desirable one and the interests of that old, tried and trusted wire, Kerite, will be perfectly safe in the hands of the subject of this little note.

ELECTRICITY WASN'T IN IT THIS TIME.

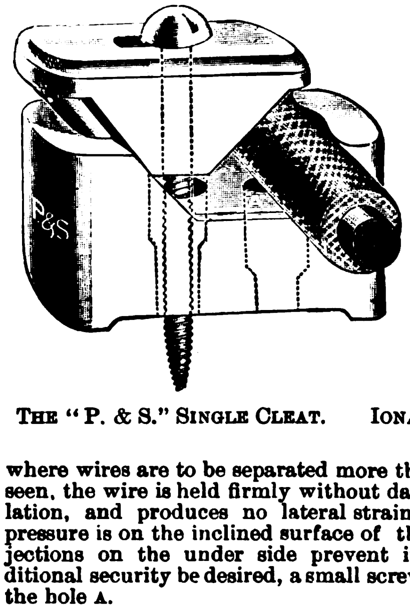
A very good story has been going the rounds lately in the city of Albany, N. Y. It seems that a short time after the celebrated Empire Express was put on between New York and Buffalo, three colored men employed in one of the large Hudson River brickyards had never seen the famous train pass, although they had heard a great deal about it, the reason being that in any position they had heretofore taken the train had passed and all the sight they had been able to get of it was a mere glimpse of the fluttering rear signal flags. Well, one day the three arranged to stand thus:—No. 1 at the north end of the yard; No. 2 at the south end and No. 3 in the middle, and as the train approached each would notify the other so as to secure a good look at the train as it sped by them. They had but a few seconds to wait. It came. The man at the south end called out: "Here she comes;" the one at the north end, "There she goes;" and the one in the middle "Gee! Whiz! Whar am she! aint she greased lightnun!" The Empire Express, is, indeed, fast enough to travel over the wires, and that is one of the reasons why it is so popular in electrical and business circles.

IONA HAND LIGHTING BURNER.

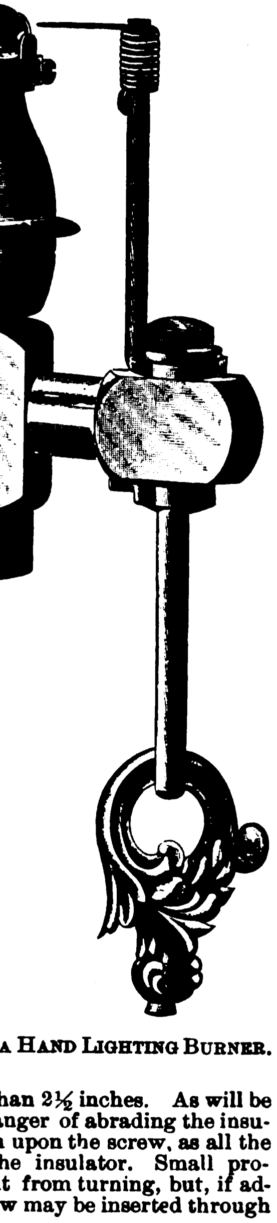
We illustrate below the Iona hand lighting burner, which is being placed on the market by the Redding Electric Co., 41 Federal street, Boston, Mass., and which, as will be readily seen from the cut, is entirely new in design and is simplicity itself. There are no cams or complicated springs to get out of order, and being operated only by the key, it is absolutely safe from leaking gas. This burner, like the Iona safety pendant mentioned in our last edition, is made in the most careful manner, the valves being hand ground and the stems made in various lengths to suit fixtures. From the orders already received by the Redding Co., these burners seem likely to have a very large sale.

THE "P. & S." SINGLE CLEAT.

Prominent among the latest novelties introduced by Messrs. Pass & Seymour, of Syracuse, N. Y., is the adjustable single cleat shown in the accompanying illustration, and designed for use where wires are to be separated more than 2½ inches. As will be seen, the wire is held firmly without danger of abrading the insulation, and produces no lateral strain upon the screw, as all the pressure is on the inclined surface of the insulator. Small projections on the under side prevent it from turning, but, if additional security be desired, a small screw may be inserted through the hole A.



The "P. & S." Single Cleat.



Iona Hand Lighting Burner.

This cleat, in common with the other specialties made by this company, is of their well known Syracuse china, thoroughly vitrified.

AN IMPORTANT LICENSE.

Queen & Co., of Philadelphia, have granted a license to George Cutter, of Chicago, to sell a new line of ammeters and voltmeters, which will be known as the "Cutler non-inductive instruments." These goods come under the Cardew patent, which is the property of the former concern, and covers instruments that make use of a heated wire.

NEW YORK NOTES.

Col. H. C. Adams, who has been the New York agent of the Fort Wayne Electric Company for some time past, has resigned that position, and will hereafter conduct the affairs of the Phillips Insulated Wire Company as its president. Its specialty is the weatherproof and damp-proof "O. K." line and house wires. Col. Adams is a very old and experienced hand at the wire business, which he goes back to with the added advantage of knowing the other side of the question. The Phillips Insulated Wire Company have a large factory at Pawtucket, and are already doing a very satisfactory trade. Col. Adams retires from 44 Broad street with many regrets on the part of his associates; and it is understood that he has received a very handsome acklowledgment of his past services from Mr. C. A. Coffin.

E. A. Gay respectfully announces that he has engaged in the general electrical specialty and supply business under the firm name of E. A. Gay & Co., with an office in the new Beckley Building, South Clinton street, Rochester, N. Y. He has the general agency for the Carpenter electric heating and cooking apparatus. Wire, cord, lamps, and other staple electric lighting supplies are carried in stock. The old partnership of Putnam, Gay & Co., is dissolved. J. E. Putnam and S. A. Ellis will continue under the firm name of J. E. Putnam & Co.

Mr. W. F. Richardson, who, by the way, is a member of the firm, the Enterprise Electric Co., of Chicago, has been making a flying trip through the East, in the interests of his company. Mr. Richardson honored this office with a call. Several large manufacturing concerns have been visited and some desirable connections made although his company has been organized but a few months. Trade has been better far than anticipated. Mr. Richardson left for the World's Fair city on Monday night.

The Genett Air Brake.—A cheering and at the same time unfortunate report comes from the New York office of the Genett Air Brake Company. The orders received by them since the street railway convention at Cleveland have "outclassed," as it were, their capacity. Moral—The many good points of this simple and yet postive acting brake were appreciated by the many interested ones who saw the mechanism in operation.

Electric Engineering and Supply Co., Syracuse, N. Y., have issued a very tasteful and effective folder in colors, calling attention to the fact that they have the order for the World's Fair detail supplies, and giving text of the order from the New York Insulated Wire Co. for the work. It is a neat piece of design and printing, and emphasizes a triumph that the Syracuse concern is justified in being jubilant over.

J. Jones & Son, 39 Vesey street, this city, report large sales of their contact protected bells. The agency in the West has now been taken by the Central Electric Co., of Chicago, who propose in the future to sell the contact protected bell only. This speaks well for the class and quality of this article, as the Central Co. is one af the largest users of these goods in the territory named.

Mr. William M. Sturges, 22 Main street, Utica, N. Y., has opened offices at the address named as a consulting electrical engineer, particularly in connection with electric railway work. He has had fifteen years' experience, and is familiar with questions of management, construction, etc. His fees for mechanical and electrical work are small.

PHILADELPHIA NOTES.

Warren Webster & Company, 491 North Third street, Philadelphia, Pa., patentees and manufacturers of the Webster Vacuum Feed Water Heater and Purifier, and licensees for the sale of patent rights of the Williames vacuum system of steam heating, report the following orders during the month of October: David Lupton Sons, Philadelphia, Pa.; Lord & Taylor, New York; Armour & Co., Chicago; Chicago Malleable Iron Works, Chicago; Boughen Engineering Company, Cincinnati, O.; Jas. McClurg & Co., Pittsburgh, Pa.; M. H. Crane, Cincinnati, O.; Lalance & Grosjean Manufacturing Company, Harrisburg, Pa.; Prahar & Bro., Brooklyn, N. Y.; Apollo Iron and Steel Company, Apollo, Pa.; Roaring Spring Blank Book Company, Roaring Spring, Pa.; Pennsylvania Railroad Company, Union Depot, Pittsburgh, Pa; Pennsylvania Steel Casting & Machine Company, Chester, Pa.; Remington Paper Company, Watertown, N. Y.; Armour & Co., Kansas City, Mo.; Botsford Paper Mill Company, Kalamazoo, Mich.; M. Price, Newark, N. J.; Risdon Iron and Locomotive Works, San Francisco, Cal.; Charles Kaestner & Co., Chicago, Ill.; Maryland Steel Company, Sparrow's Point, Md.; Commonwealth Hotel, Harrisburg, Pa.; Harrisburg Foundry and Machine Company, Harrisburg, Pa.; Crompton Company, Quidnick, R. I.; American Fire Engine Company, Seneca Falls, N. Y.; Royal Weaving Company, Pawtucket, R. I.; Pennsylvania Steel Company, Steelton, Pa., this order being for 8,250 h. p. They have just issued a new catalogue, and visit plants at their expense, and furnish apparatus upon trial under guarantee.

The Spreckels Sugar Refinery.—A notice has been going the rounds of the press of the increase in the Spreckels Sugar Refinery in Philadelphia, calling for the placing of five large engines. One of these is to drive an addition to their electric light plant, consisting of an 800-light toothed armature alternating dynamo and exciter for same, which will go in their present dynamo-room and be coupled in to the present system. This increase makes this isolated plant take rank as one of the largest in the country, the total capacity being over 3,000 lights, and the whole arranged as a central station; no fewer than 24 separate circuits being carried to different parts of the buildings. The original plant was installed several years ago by Messrs. M. R. Muckle, Jr. & Co., and it is notable that it has operated till the present time without costing a dollar for repairs, and for the greater part of this period has been run night and day. The contract for the new plant goes to the same firm. No gas piping whatever has been installed in the refinery, and it is interesting to note that the total cost of the original electric light plant including the dynamos, engines, convertors, wiring, etc.; in fact, all details except boilers, was no more than the bid for properly piping the entire refinery for gas. The bid for piping included, however, a six-inch main to be run for two squares in the street since there was no main immediately at the refinery of sufficient capacity to supply the amount of gas which it was calculated would be needed to light the works.

A Reception at Queen & Co.'s Laboratory, Ardmore.—At the invitation of Messrs. Queen & Co., a large party of gentlemen visited the laboratory of the company at Ardmore, a short distance from Philadelphia, last Saturday. Upon their arrival they were shown over the building and given the opportunity to inspect the methods employed by Queen & Co. in constructing and testing the large variety of electrical instruments manufactured by them. The visitors were afforded ample opportunity of judging of the variety of work by an excellently arranged exhibit of the Queen instruments, to which were added a number of foreign make. Among the latter was a Boys radio-micrometer, the first brought over to this country. The party were very handsomely entertained at luncheon. Mr. E. G. Willyoung, superintendent of the laboratory, deserves great credit for the success of this most entertaining and instructive affair, which was greatly enjoyed by all present.

The Philadelphia Engineering Works, manufacturers of the Philadelphia Corliss engine, have under construction over 40 engines, ranging in power from 50 to 500 h. p., among which are two 500 h. p. vertical cross-compound condensing engines for the Hudson Electric Light Co., of Hoboken, N. J. The plant is designed for four of these massive engines, two of which will not be shipped for several months. The fly-wheels will measure 17 feet in diameter, 54 inch face, and will weigh 45,000 pounds each. The speed will be 100 revolutions per minute. These engines are designed to operate an arc and incandescent plant and railway generators. The Philadelphia company are about to ship two large double compound condensing tandem engines, for the Springfield (Mass.) Armory; two tandem compound non-condensing engines, for the Omaha Grant Smelting Co., of Denver, Col., and two coupled high pressure engines, for the Watervliet Arsenal of West Troy, N. Y.

Messrs. M. R. Muckle, Jr., & Co. have lately finished the installation for the Weisbrod and Hess Brewing Company, of a 350-light dynamo and 35 h. p. Westinghouse Standard engine. The lights displace all other kinds of illumination throughout the brewery and have proved themselves of especial value in the beer cellars. A feature of the installation is the use in several places of 150 c. p. lamps in preference to groups of lamps of smaller candle power. This week there is a large trade display on the street which runs past this brewery, and a handsome arch has been erected, on which a large amount of decoration has been done with incandescent lamps to be operated from the brewery dynamo. This work is of course only temporary but has a very fine effect.

Mr. C. S. Clunn, a well-known mechanical and electrical engineer, has opened offices at the Scott Building, 1217 Filbert street, where he will act as agent for the Hoover, Owens & Rentschler Company, builders of the Hamilton-Corliss Engine and the Valley Iron Works, of Williamsport, Pa. Mr. Clunn is prepared to install complete steam and electric light plants, including construction work, and has contracts for several which are now under way.

The Fort Wayne Electric Co., through their agent, Mr. G. A. Wilbur, have sold an additional 75 Wood arc light machine to the Millville (N. J.) Electric Light Co., and 60 Wood double arc lamps of the new clutch style to the Powellton Electric Co.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.

THE
Electrical Engineer.

VOL. XIV. NOVEMBER 30, 1892. No. 239.

THE LIGHTING OF WASHINGTON PARK, CHICAGO, ILL.

BY

Fred A. Schaffler

WASHINGTON PARK is located in the south-eastern part of the territory now included and known as Chicago proper, and is one of the many parks controlled exclusively by the Board of Commissioners of South Parks and Boulevards. The lighting of Washington park and adjoining Boulevards was formerly accomplished by the ordinary gas lamp-post system. The entire park and the four principal Boulevards are now illuminated by the most comprehensive system of park underground installation ever undertaken by any city in the West, if not in the United States.

The electric companies throughout the country fully realized the value of the opportunity to equip such a plant, and much sharp competition was the result of the commissioners' advertisement for bids for the work which occurred in February last. The specifications were unusually exacting in all details, especially that of insulation of the dynamos in multiple and single, and in the line and underground construction.

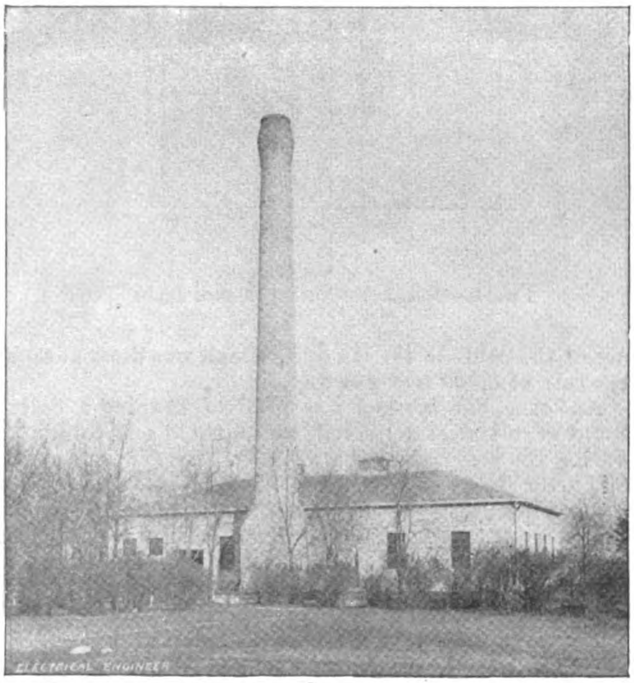


FIG. 1.—ELECTRIC LIGHT STATION, WASHINGTON PARK, CHICAGO.

The contract for the entire plant was awarded to the Brush Electric Company, from among five competitors, and they sublet it as follows: The steam plant to Messrs. Fraser & Chalmers, of Chicago, who furnished their new type of high speed Corliss engines and Campbell & Zell safety water tube boiler. The underground cables were sublet to the Safety Insulated Wire Company, and the tubing work was given to Thomas Jackson & Son, who did the work under the direct supervision of the Brush Electric Company's representative.

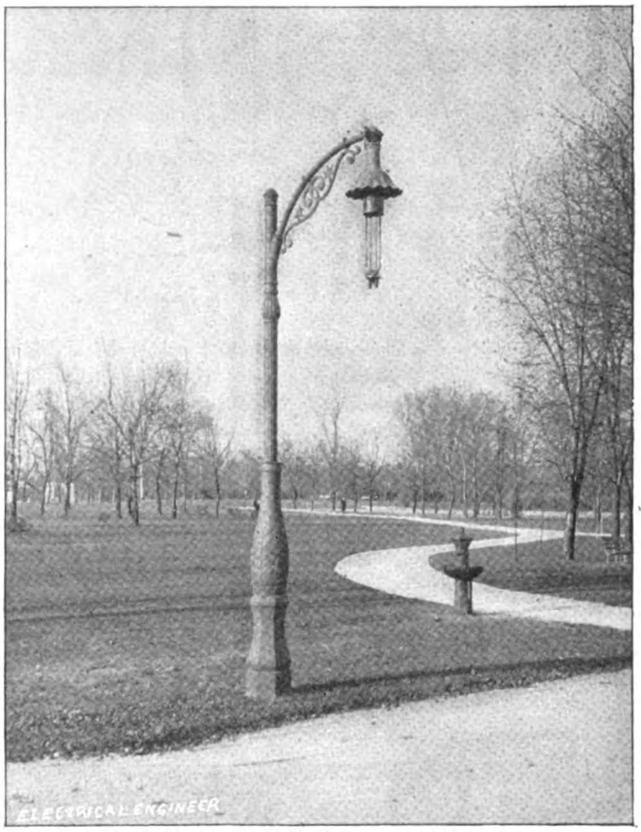

FIG. 2.—ORNAMENTAL LAMP POST, WASHINGTON PARK, CHICAGO.

The station plant Fig. 6, consists of three 10 x 14½ x 24-inch non-condensing compound engines, each of 110 h. p., running at 140 revolutions per minute, belted direct from six 10-inch pulleys to six Brush dynamos, each having a capacity of 50 lamps of 2,000 c. p. each. The belt speed is 4,350 feet per minute. The engines have capacity to operate three extra dynamos of the same size, when such increase of plant is deemed necessary. The station is fully equipped with all electrical apparatus of the latest type, and is also furnished with a switch-board of proper design to accommodate eight dynamos and eight circuits, and arranged to quickly transfer any dynamo on any circuit with specially devised safety cables and plugs. This switch-board is also fitted with an exceedingly ingenious ground detector for locating grounds, at the station, any circuit. Steam is supplied by the water tube boilers at a pressure of 120 pounds per square inch. The commissioners built a very substantial power house to accommodate the plant, according to the designs of their engineer, Mr. Charles Livings. All the installation has been, on behalf of the commissioners, under the direct supervision of Mr. J. Frank Foster, general superintendent of South Parks.

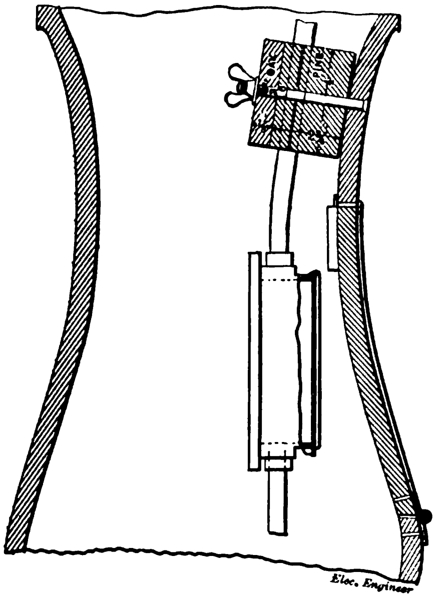

FIG. 3.—CUT-OUT SWITCH IN LAMP POST.

The outside work consists of 29¼ miles of cables laid underground in a conduit made of 1½-inch and 2-inch steel pipe, standard gauge, with screwed couplings, and is laid from 14 inches deep in lawns to 5½ inches deep under cable railway crossings. The underground cable consists of No. 5 solid B. & S. gauge copper wire covered with $\frac{3}{16}$-inch rubber insulation, one wrapping of tape outside of this, and the whole covered with a lead casing $\frac{3}{16}$-inch thick. The specifications called for this cable to have an insulation resistance of 100 megohms per mile when disconnected, and the system to have an insulation resistance of one megohm when connected with lamps and dynamos in running order.

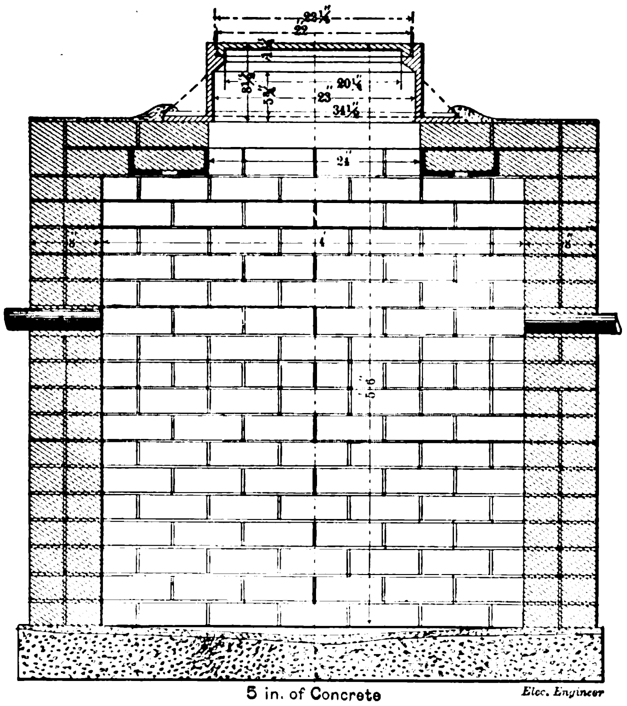

FIG. 4.—MANHOLE, WASHINGTON PARK, CHICAGO.

The conduit throughout the system is furnished with 30 deep manholes and 340 handholes at proper locations, the manholes being placed where there are more than two cables in the conduit. These manholes, Fig. 4, are made in circular form, of hard brick, and are thoroughly water tight in construction, the roof and cover being supported by heavy T irons. The handholes are cast iron receptacles of ample size, furnished with self-locking covers, also of cast iron.

Considering the fact that the ground was not broken until August 1, and the entire underground work, including the foundations for the lamp-posts, was completed by September 27, much credit is due to the persons immediately in charge of the work for the rapid completion of the undertaking. A little calculation will show that, deducting Sundays and days on which the weather interfered, the actual number of working days was forty-six, and that the average amount of conduit laid per day was 2,152 feet. On several occasions 6,000 feet was laid per day of ten hours. The above, of course, does not include the laying or drawing of the cable in the conduit, which was done at an average rate of 5,000 feet per day.

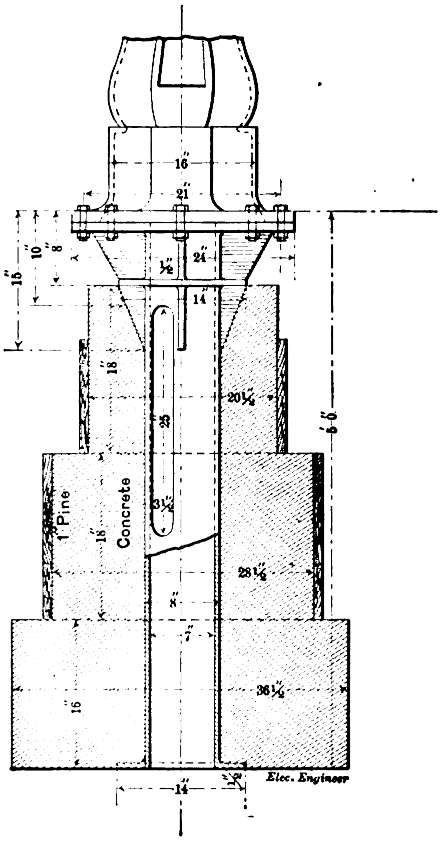

FIG. 5.—BRICK FOUNDATION FOR LAMP POST.

An excellent method was used of keeping a daily account of material delivered, conduit laid and cable drawn, during the progress of the work. It is very interesting to look over these daily records as the work progressed—or did not progress—as they show specifically just what the causes for delay were—sometimes on the conduit blanks, non-delivery of sufficient material, stones and rocks, cable railway or a network of piping, or other causes.

There are 260 lamp-posts of special design, approved by the commissioners. Each post is of cast iron, and is supported on a substantial brick foundation, shown in section in Fig. 5. The general design of the post complete may be seen in the view, Fig. 2, which shows the lamp located in front of the Park casino. The post carries a hood also specially designed and approved, the whole harmonizing well with the surroundings. The lamps are hung somewhat lower than is the usual custom for this class of illumination, principally on account of there being many placed under trees in the Park; but they are distributed generously, so that the effect is an excellent general illumination. Each post is also furnished at the base with an independent switch for cutting out the lamp and short circuiting it, access to which can only be obtained by opening with suitable key a door in front of the switch. The latter, as shown in Fig. 3, is mounted on a hard rubber base $\frac{1}{2}$ inch thick, and is encased in a cast iron box fitted with a sliding glass cover. The hood is furnished with the usual hanger board and cut-out switch. There was used in wiring the lamp-posts two miles of No. 5 B. & S. flexible cable, covered with $\frac{3}{16}$-inch rubber, taped and braided.

The plant was started in operation for the first time on October 20, on Park circuits, just in time to assist materially in the ceremonies connected with the dedication of the World's Fair. The entire installation was in operation November 1. The type of lamp in use on this system is the now well-known Brush-Adams No. 31, 2,000 c. p. double arc lamp.

The whole system, as installed and operated, is unquestionably a model one for use in large cities where such parks and boulevards or streets should be as well illuminated as practical and scientific methods, and the finances of the city, will permit, whether the city owns the plant or purchases the illumination from a lighting company.

To Mr. Alex. Dow, engineer of the Chicago district of the Brush Electric Company, should be given the credit of pushing the work forward, in a careful and systematic manner, as the work on behalf of the Brush Electric Company has been under his direct supervision.

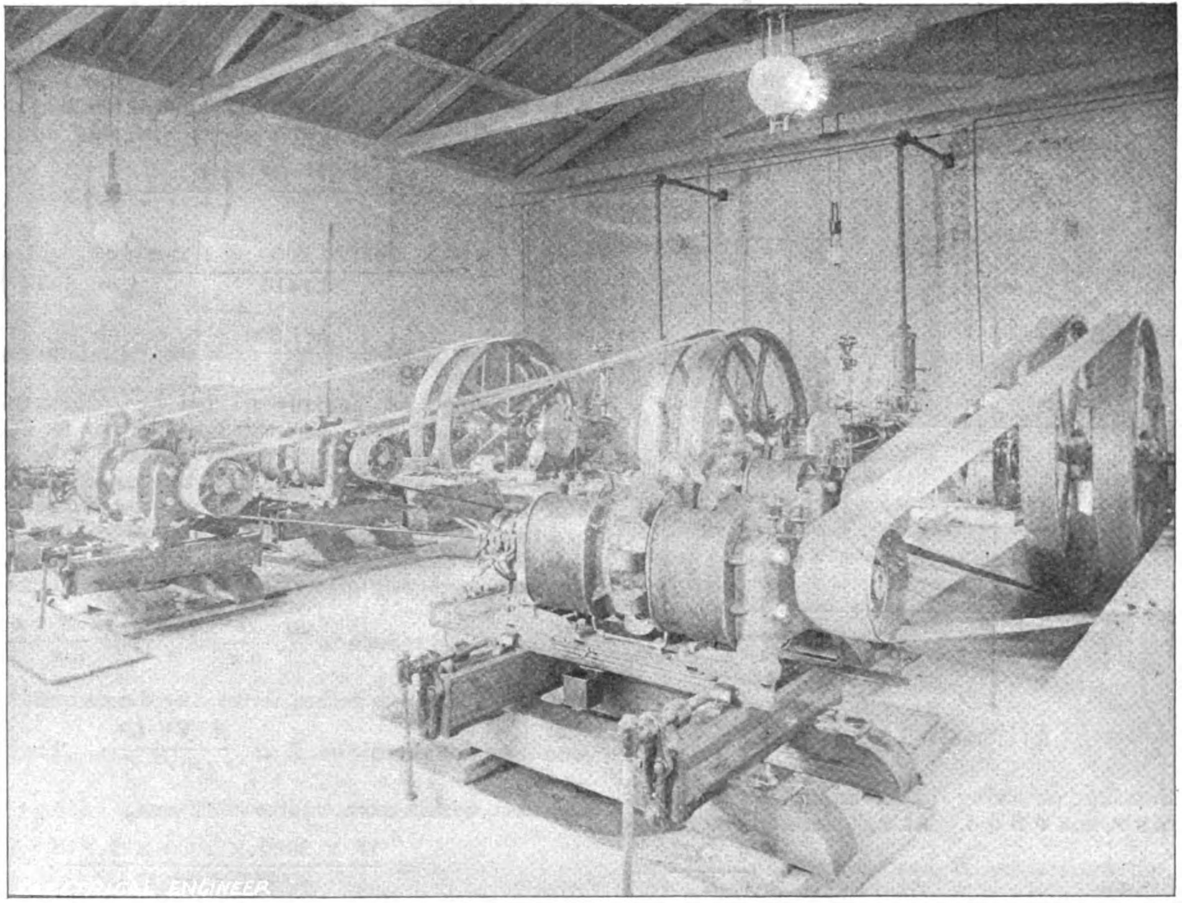

FIG. 6.—ELECTRIC LIGHT PLANT, WASHINGTON PARK, CHICAGO, ILL.

THEORETICAL ELEMENTS OF ELECTRODYNAMIC MACHINERY.[1]—XIII.

BY

A. E. Kennelly

ALTHOUGH the distribution of stress in a magnetic circuit may always be found by summing the vector products of flux and current on each element of conductor, it is sometimes more readily obtained by determining the local values of $\frac{B^2}{8\pi}$ throughout the system, and from these their resultants.

As an example of some practical importance, we may consider a closed hollow ring or circular solenoid with a uniform winding of N turns, a square cross section of A sq. cms. $= b^2$, and generating radii of r and R cms. as represented in plan and diametral section by Fig. 33. By preceding results, we know that when excited by a current of C units, the intensity B within the core at any radius ρ is $\frac{2\,N\,C.}{\rho}$ The flux paths are all circles and exert a tension of $\frac{B^2}{8\pi}$ dynes per sq. cm. along these circles, but which tensions are nowhere directly impressed upon the walls of the ring. If the intensity within the ring were uniform, the total tension exerted across any section

---

[1] Copyright 1892, by A. E. Kennelly.

PR of the hollow core would be $\frac{A\,B^2}{8\pi}$, but since the intensity diminishes outwardly, the total tension must be found by subdivision of the area into elements and summing the elementary tensions on each. In this instance the surface integral of the tension $T = \int_r^R \frac{B^2}{8\pi}\,dA$, where

$$B^2 = \frac{4\,N^2\,C^2}{\rho^2} \text{ and } dA \text{ becomes } b.\,d\rho, \text{ so that}$$

$$T = \frac{4\,N^2\,C^2\,b}{8\pi}\int_r^R \frac{d\rho}{\rho^2} = \frac{N^2\,C^2\,b}{2\pi}\left(\frac{1}{r} - \frac{1}{R}\right) \text{dynes},$$

and this is the stress exerted across any radial sections such as P R and S Q when the thickness of the conductor wound on the ring need not be considered.

The stress that is directly brought to bear upon the walls of the core consists of the side thrust or outward pressure of $\frac{B^2}{8\pi}$ dynes per sq. cm. The stress on the plane surfaces D E F G, and H J K L being equal, opposite, and equilibrating through the substance of the walls, may be omitted from consideration, reserving for examination the curved surfaces R E S F, and P D Q G. At any point on the former and outer circumference, *B* has the value $\frac{2\,N\,C}{R}$ and the pressure is $\frac{1}{8\pi} \times \frac{4\,N^2\,C^2}{R^2}$ dynes per sq. cm. radially outwards. At any point on the inner surface, *B* is $\frac{2\,N\,C}{r}$ and the pressure is $\frac{1}{8\pi} \times \frac{4\,N^2\,C^2}{r^2}$ dynes per sq. cm. directed towards the center O. Two symmetrical systems of stress are thus established, one resident at the outer circumference and directed radially outwards, the other resident at the inner circumference and directed radially inwards.

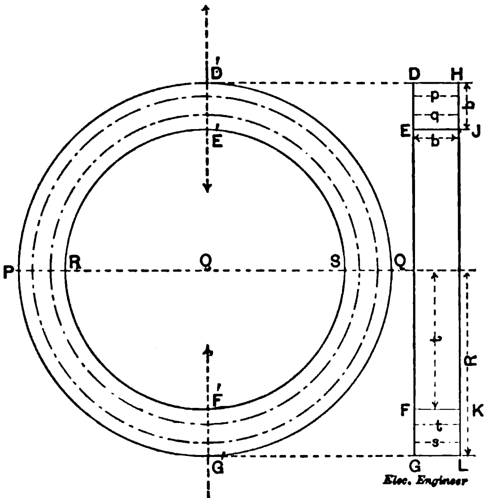

Fig. 33.

Selecting any diameter, such as P O Q, the resultants of the first system directed across this plane are stresses $\frac{b\,N^2\,C^2}{\pi R}$ dynes along O D', and O G', while the resultants of the second system are two equal stresses of $\frac{b\,N^2\,C^2}{\pi r}$ dynes along E' O, and F' O, respectively. These forces do not equate but leave a balance directed inwards of $\frac{b\,N^2\,C^2}{\pi}\left(\frac{1}{r} - \frac{1}{R}\right)$ dynes along E' O, and F' O. This will be the stress which, if the ring were actually divided by the plane P O Q, the two halves would mutually exert upon each other, or the magnetic attraction which they would evince. Its amount would be equally shared between the two sections P R, and S Q by symmetry, and each section would support a stress of $\frac{b\,N^2\,C^2}{2\pi}\left(\frac{1}{r} - \frac{1}{R}\right)$

The stress exerted tangentially through the walls of the solenoid may be ascribed to the resultant side thrust from the flux and is here equal to the total tension exerted by the flux within the interior. This proposition has very general applications, for in any active coil it is evident that equilibrium could not exist across any section of the coil, unless the stress supported by the substance of the walls counterbalanced the total tension of the flux, and the resultant tension is generally more readily determined than the resultant pressures that equate it.

As a numerical illustration of the foregoing case presented in Fig. 33, let $r = 10$, $R = 14$, $b = 4$, $N = 2000$, $C = 2$ (absolute units) or 20 amperes. Then the total force exerted across any diameter of the ring would be

$$T = \frac{b\,N^2\,C^2}{\pi}\left(\frac{1}{r} - \frac{1}{R}\right)$$

$$= \frac{4 \times 2000 \times 2000 \times 2 \times 2}{3.1416}\left(\frac{1}{10} - \frac{1}{14}\right)$$

$$= 581{,}900 \text{ dynes} = \frac{581{,}900}{981} = 593.2 \text{ grammes weight.}$$

If the ring were actually divided by a diametral plane P O Q the upper half, suspended at its centre E^1, would support the lower half vertically beneath it by magnetic force under these conditions, if the mass of that lower half did not exceed 593 grammes, each section, P R and S Q exerting a total stress of 296.5 grammes weight.

If the difference of intensity over the cross-section of the ring were negligible, the tension exerted across any section would reduce to $A.\,\frac{B^2}{8\pi}$ simply, or $\frac{A}{8\pi} \cdot \frac{4\,N^2\,C^2}{r^2}$ and the total stress acting across any diameter of the ring would be double this or $T = \frac{A\,N^2\,C^2}{\pi\,r^2}\cdot$ Thus in the last case, with a mean radius of 12 cms.,

$$T = \frac{16 \times 2000 \times 2000 \times 2 \times 2}{3.1416 \times 12 \times 12}$$

$$= 565{,}800 \text{ dynes} = 576.8 \text{ grammes weight.}$$

The tension across each section being 283.4 grammes weight and by the adoption of the approximate formula, the stresses would have been here underestimated by about three per cent.

The formulæ indicate that the tensions exerted across a section of any closed circular solenoid without iron, are proportional to $(N\,C)^2$ or the square of the current turns. This is a direct consequence of the facts that *B* is proportional to the current turns, and the tension in its turn is proportional to B^2.

We may next consider the distribution of stress within a double solenoid or pair of concentric rings, one of which is enclosed within the other. Such a system is related to the practical case of a solenoid with more than one layer in its winding. In Fig. 33, the dotted lines through *p q s* and *t* represent the walls of an internal concentric ring of radii r_1 and R_1, current C_1 and N_1 turns. All the walls of the double solenoid may be supposed rigid, but of negligible thickness.

Exciting the outer coil only, the intensity at any point within it of radius ρ will be $B_0 = \frac{2\,N\,C}{\rho}$. Exciting the inner coil only, the intensity will be $B_1 = \frac{2\,N_1\,C_1}{\rho}$ at any point within its walls, but zero beyond them. Exciting both coils simultaneously, the intensity at any point in the internal ring will be that due to both coils, or

$$B_0 + B_1 = \frac{2}{\rho}\,(N\,C + N_1\,C_1.)$$

For a point within the outer ring but without the inner, $B_0 = \frac{2\,N\,C}{\rho}$ remains undisturbed.

The stress per sq. cm. under these conditions will be $\frac{(B_0+B_1)^2}{8\pi}$ within the inner ring, and $\frac{B_0{}^2}{8\pi}$ within the outer only. Across any section such as S Q, the surface integral of tension over the inner ring will be

$$t_1 = \frac{b\,(N^2\,C^2 + 2\,N\,N_1\,C\,C_1 + N_1{}^2\,C_1{}^2)}{2\,\pi}\left(\frac{1}{r_1} - \frac{1}{R_1}\right)$$

Similarly between radii r and r_1 of the outer ring the total tension will be $t_2 = \frac{b\,N^2\,C^2}{2\,\pi}\left(\frac{1}{r} - \frac{1}{r_1}\right)$ and again between radii R_1 and R, $t_3 = \frac{b\,N^2\,C^2}{2\,\pi}\left(\frac{1}{R_1} - \frac{1}{R}\right)$. The total tension across the entire section must be $T = t_1 + t_2 + t_3$.

It might, at first sight, be supposed that since the total tension within the inner ring is t_1, its walls must sustain a stress of this amount. If, however, the side thrust pressures due to the intensities adjacent to the walls, be summed and compounded, it will be found that the stress on those of the inner ring will only be

$$\frac{b\,(N_1{}^2\,C_1{}^2 + 2\,N\,N_1\,C\,C_1)}{2\,\pi}\left(\frac{1}{r_1} - \frac{1}{R_1}\right),$$

while the balance of t_1, or $\frac{b\,N^2\,C^2}{2\,\pi}\left(\frac{1}{r_1} - \frac{1}{R_1}\right)$ is supported by the stress from the external intensity B_0, and is carried over to the outer coil. The stress supported by the walls of the outer ring is thus increased to

$$\frac{b\,N^2\,C^2}{2\,\pi}\left\{\left(\frac{1}{r} - \frac{1}{r_1}\right) + \left(\frac{1}{r_1} - \frac{1}{R_1}\right) + \left(\frac{1}{R_1} - \frac{1}{R}\right)\right\}$$

across any section, or simply $\frac{b\,N^2\,C^2}{2\,\pi}\left(\frac{1}{r} - \frac{1}{R}\right)$; and this would be the stress on those walls if the inner ring were absent or remained unexcited.

In a compound circular solenoid, therefore, the total stress sustained by all the walls together is equal to the surface integral of tension over the whole area to the limits enclosed by the outermost, but its distribution among the rings is such, that the inside coils take less than the integral tensions over their own sections, leaving the balance to the walls outside. This tends to secure a more uniform distribution of the total tension on the walls. The outside layer always carries the stress that it would support if all the inner rings were removed or left unexcited.

The introduction of iron into the magnetic circuit produces no change in stress principle, but usually a great change in its degree. If the magnetized iron be regarded as the equivalent of a certain solenoid, or combination of solenoids, the magnetic stresses that would be developed in that equivalent solenoid, are developed in the iron. While, however, we have seen that equilibrium of stress exists throughout the hollow core of a simple coil or solenoid, and that stress is only manifested in the walls, or turns of active conductor, the stress in iron is developed throughout its substance. A uniformly magnetized bar of iron when divided across by any plane exhibits attractive force between the severed portions all over their opposed areas, just as its equivalent solenoid would do, if the insulated wire was spirally wound in a groove on a core of copper or silver, so rigidly that the stresses exerted by the wire became imparted to the encircled substance. Apart from the artificiality of the hypothesis by which an equivalent solenoid is substituted for a magnet, this distribution of the stress through the substance of the iron must follow from the molecular nature of magnetization demanding in strictness a correspondingly large number of molecularly small solenoids to adequately represent the theory, whereas, for practical magnetic purposes a single solenoid representing the entire mass might give sufficient approximation.

INCREASED COMMERCIAL EFFICIENCY AND HIGHER ECONOMY IN CENTRAL STATIONS.—III.

BY

J. H. Vail

CONDENSERS.

The expert engineer is, of course, familiar with the value of each type of condenser, but a brief explanation of the different types, the requisite conditions for their use, and the saving to be derived may be of interest to central station managers.

Under favorable conditions, we may expect a marked saving in coal by the application of the condenser. This saving should be from 20 to 25 per cent. and yet it is possible that by employing a condenser wasteful of steam or with engine and exhaust pipes in leaking condition, the condenser may cause a positive loss. Condensers should preferably be used with compound or triple expansion engines.

One of the essential conditions is an ample supply of cold water. Another important point is that the system of exhaust piping shall be absolutely air tight. Special attention must be given to the pipe joints, piston and valve rod packing, and all leaks should be stopped, no matter how minute. The writer has seen an increase of several inches in vacuum by simply hunting out and stopping small air leaks.

The economy to be secured by the condenser is due to the vacuum formed on the exhaust side of the engine piston and the consequent removal of atmospheric pressure therefrom as well as back-pressure in exhaust passages and pipes. The application of the condenser removes the back pressure and forms a constant vacuum equal to from 12 to 14 pounds per square inch on the exhaust side of the piston; the steam can consequently be expanded to nearly absolute zero pressure, thereby obtaining its full expansive power.

We will briefly review the condensers under two divisions or types, viz., Surface Condensers and Jet Condensers. As to the leading conditions under which one or the other type of condenser should be applied, I will assume that the cost of feed water is the essential point on which the decision should usually be made. There may be other conditions which are of minor importance, but we will leave them for future attention.

Surface Condensers.—The surface condenser with its appurtenances, *saves* the condensed steam which is delivered to the hot well and the water may be used over continually for boiler feed, the waste of feed water being very small. The circulating water being separate from the condensed steam, it may be salty or otherwise unfit for boiler feed; its principal requisite is low temperature. The surface condenser should be used where feed water is expensive and where water for condensation is not sufficiently good to be combined with the feed water and returned to the boilers. Therefore, its economy in saving feed water is a matter that should not be overlooked, as the feed water saved may soon more than repay the extra cost of surface condensers. As an illustration, in the Cincinnati Edison Station, condensing water (unsuitable for boiler feed) is obtained from artesian wells; with 600 h.p. average daily service, the total cost of water from city mains is about $4 50 per month, the same feed water doing constant service with but slight addition of supply from city mains.

The jet condenser, when applied in the customary manner, does not save the feed water. In original cost and in the cost of maintenance, the surface condenser is more expensive than the jet condenser. For a given horse power station capacity, the surface condenser and its necessary appurtenances, hot well, etc., will cost fully twice as much as the jet condenser.

A point of advantage that may be placed to the credit of the surface condenser with its air and circulating pump, is, that it can be started independently of the engine, thus forming a partial vacuum in advance of starting the engine. The grease taken up by the steam during its work in the cylinders is partially retained and held in suspension in the condensed water; this grease must be thoroughly extracted so as to avoid injury to boilers.

The Jet Condenser.—With the independent air pump and jet condenser, the exhaust steam from the engine is admitted into the top of the condenser and on its descent is met by a fine spray of cold water; the complete mechanical mixture of steam and induction water is thus obtained. The water deprives the steam of nearly all its latent heat, condenses it, and a vacuum is formed. With the jet condenser, it is understood that the feed water is united with the water of condensation and discharged. If, however, the condensing water is suitable for boiler feed, then an efficient form of grease extractor should be inserted in the exhaust pipes between engines and condenser, and the discharge from jet condenser can be run to a hot well and from there used as boiler feed; in this case the original feed water is saved, as with the surface condenser, but the feed water will be several degrees lower in temperature than from the hot well of surface condensers.

When a feed water heater is already located, if air tight, it need not be laid aside, as the same will partially act as a surface condenser between the engine and the independent condenser, the interposed heater increasing the temperature of the feed water, probably to about 150° F. Great care must be taken to insure against air leakage through heater shell and connections.

Therefore, we may say that when feed water is costly, use the surface condenser which saves it, and when feed water is cheap enough to be thrown away, use the jet condenser. The latter will apply when the condensing water is salty or unfit for boiler feed. Also by comparing the annual cost of water for boiler feed with the difference in cost between the surface or jet condenser, and the interest on the same, we can readily determine which type to apply.

The quantity of condensing water required depends upon its capacity for cooling, the lower the temperature the less water necessary. In this latitude, the water required will be from 20 to 25 times the amount required for boiler feed. There will be found certain stations of medium capacity where there is not obtainable a 24-hour supply of condensing water. Such a station might with profit be arranged so as to run a simple high pressure engine for all hours of light load, storing in reserve the water supply to be used with condensing engines during the few hours of heavy load. This type of combination station cannot fail to show good results.

INSULATED ELECTRIC CONDUCTORS.[1]—XIV.

BY

James Bowstead Williams M.E.

REMARK 3. Any remarks upon the third statement are almost superfluous, for it is evident that if lead or any other metallic conducting substance is present in a layer of paint, the I. R. of such layer is necessarily diminished in proportion to the amount of conducting material it contains. Lead compounds may be used in fireproofing paints, however.

Remark 4. No volatile liquid should be used as the *only* solvent for paint. If used at all, there should always be a non-volatile fluid, such as oil, used with it, so that the paint, when dry, may be tough and flexible. Unless oil or *its equivalent* is used, and in suitable proportions, the hardened paint is apt to soon become brittle, and also detached from the fibre.

Remark 7. Statement 7 can best be explained by a practical example. Take a wire covered with one thick braid, and saturate the braid with a paint containing a considerable amount of any volatile solvent. As soon as the paint is exposed to the atmosphere the outermost portion of the layer of paint dries first of all, and this hardened surface will then act as a barrier to the free exit of the volatile solvent in the paint beneath it, and the body of the paint will remain in a liquid state for some time. When the solvent does finally evaporate the paint will be found to contain numerous small air spaces which cause the entire covering of the wire to act somewhat like a sponge in absorbing moisture. Furthermore, this irregular drying of such a paint will also prevent paint subsequently applied from passing into and filling the spaces left after the first application unless a vacuum be used. Therefore, but one application of paint should be made to form a dielectric or layer thereof; and the proportion of solvent to solids should be such that the entire body of paint will either of itself harden uniformly or can be made to do so, and that few or no air spaces may be left in the covering. No rules can be given for this proportion, and experiment alone can determine it. In other words, every separate combination of solids will require a certain amount of solvent, and this amount can be ascertained only by preparing several specimens of the paint, saturating fibre on wires with them, and then selecting the best.

Remark 8. Driers may be used in some cases to accelerate the drying of oil in paints. But such driers should contain no lead or zinc salts when used, although they may have been prepared by the aid of such salts. The best driers are those containing a large proportion of shellac. Driers, although they facilitate the change of oil from a liquid to a flexible solid form, when the oil is exposed to the air, also cause the oil to change to a brittle resinous mass sooner than if the driers were omitted.

Remark 10. A good test of a paint is that it will not change in color or consistence, nor deposit *any* of its ingredients, after standing for several days, or even weeks. Nor must any of its ingredients separate during the drying of the paint. All of the ingredients must be freely soluble in the solvent or solvents used. Many paints which are apparently chemical solutions when fabricated will deposit some of their principal ingredients after standing for three or four days. The writer found this to occur more frequently when the hard resins, amber, copal, and shellac form a principal ingredient of paints.

---

[1] *Copyright, 1892, by J. B. Williams.*

Remark 11. The writer has never yet been able to find a composition or combination of ingredients which could be combined and applied by means of water but what would dissolve in water after it had hardened either in air or by the aid of heat. Again, many commercial liquids which could be used as solvents contain water when purchased. This is especially the case with oil of turpentine.

A BIOGRAPHICAL SKETCH OF THE KHOTINSKY ACCUMULATOR.—VIII.—(*Concluded.*)

BY

Capt. A. de Khotinsky

THE reasons which have led up to the construction of the present form of my accumulator have already been given, and it now only remains to show in what manner this construction has been carried out in practice. The engraving, Fig. 36, shows one section enlarged, of the plates shown in Fig. 37. The latter shows two plates built up of five horizontal strips laid one above the other, as seen in the engraving Fig. 38, which shows the plates assembled ready to be placed in the containing jar. The horizontal strips are placed together at certain distances from each other, and the lugs cast in the lead frame surrounding the plates, serve to support the cell upon glass plates, which raise the bottom of the elements a short distance above the bottom of the jar. This permits free circulation of the electrolyte, as well as avoids the danger of short circuiting from any material which might accidentally fall to the bottom. The engraving, Fig. 39, finally shows the cell as built ready for use.

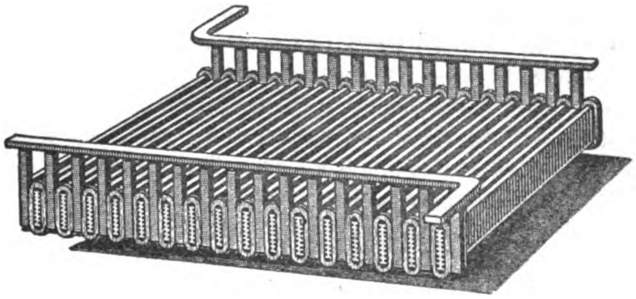

FIG. 36.

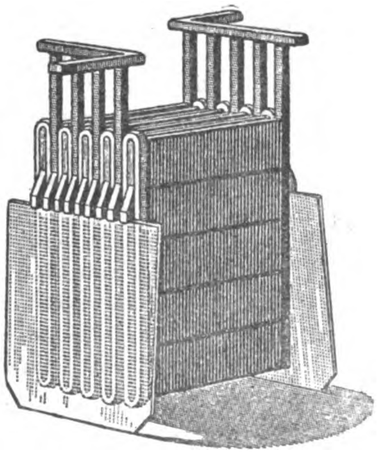

FIG. 38.

From the record of my work here concluded, it will be evident that the experiences which I have passed through have enabled me to learn what to avoid in the construction and operation of storage batteries. I confidently believe that the type of cell which is the result of all these experiences fulfills all the demands which the most exacting practice can call for.

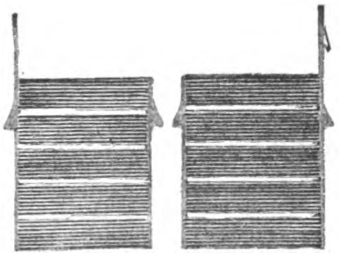

FIG. 37.

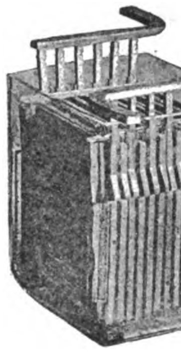

FIG. 39.

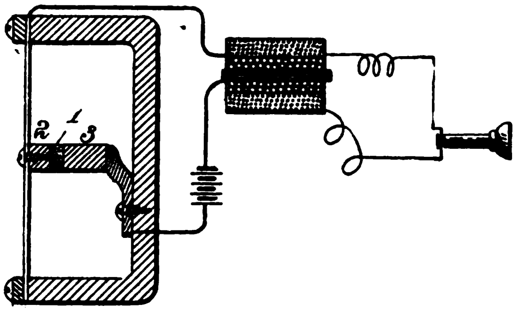
THE CLAMOND MICROPHONE.

A NOVEL method of overcoming the difficulties due to imperfect variation of resistance in telephone transmitters has recently been devised by Mr. Charles Clamond, of Paris, in which the resistance employed consists of a plastic body placed between the electrodes and lending itself readily to their vibrations; becoming long and thin, or short and thick, as the electrodes recede from, or approach, each other. The accompanying illustration shows a vertical section of the device included in the working circuit of a transmitter. The diaphragm has secured to its case the electrode (2), while a second electrode (3) is supported by a bracket fastened to the casing as shown. Between these, and adhering to each, is the plastic resistance (1), surrounded by a very thin casing of elastic, non-conducting material.



CLAMOND MICROPHONE.

The working resistance is made by mixing metallic or other conducting powders with viscid, non-conducting liquids or plastic substances, such as glycerine or vaseline, and the casing is made by coating the resistance with collodion or some similar substance.

ELECTRIC TRACTION IN BROOKLYN.

THE cars have been steadily arriving for the Atlantic Avenue Road in Brooklyn, from the St. Louis Car Company, St. Louis, Mo., equipped with Westinghouse motors on Peckham trucks. The road will be started as soon as the power-station is completed, which will take about two months.

The foundations are nearly ready for the building that will contain the power plant for the Eastern district of the Brooklyn City Electric Railroad. This power station will have a capacity of 12,000 h. p. The building is located at the foot of Division avenue on the river front.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 203 *Broadway, New York City.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

Scientific knowledge makes the great man greater, adding to his powers, while it guards the weaker brethren from many follies.—Fleeming Jenkin.

THE COST OF ELECTRIC SUPPLY.

HOWEVER great an engineering enterprise may be and whatever credit it may reflect upon its projectors and those who carry it out to completion, the fact remains that there are very few such undertakings which can be for one moment considered, independent of the question, Does it pay? We might go further even, and say that, as a rule, the engineering enterprise that does not pay, whatever benefits may accrue to those directly influenced by it, is a drawback to the development of the profession, in that a bad investment must shake the courage and confidence of capitalists, by whom such enterprises must of necessity be carried through. Electrical distribution as an engineering enterprise is no exception to this rule, but the designer of a station has now sufficient data at hand to so plan the details of construction and operation that he may be able to tell, with a tolerable degree of certainty, just what revenue can be expected from a station of given size in any particular locality. As an example of a method of predetermination of the probable cost of supplying electricity, we may call attention to the recent presidential address by Dr. John Hopkinson, F. R. S., delivered before the Junior Engineering Society in London.

Dr. Hopkinson starts by stating broadly that to attain the best results, a scientific engineer ought to have in charge the working out of the plans. In analyzing the elements which confront the engineer in a design of this nature, it is shown that the expenses of an engineering undertaking may be broadly divided into two classes. Thus, we have, first, the expenses which are quite independent of the extent to which the undertaking is used, and again, expenses which are absent unless the undertaking is used, and which increase in proportion to the use. Again, in some undertakings the service which the undertaking is designed to render can be performed at a time selected by the owners; in others, at a time selected by him to whom the service is rendered.

In the application of these principles to the supply of electricity for lighting, Dr. Hopkinson has chosen an imaginary station designed to supply 40,000 16-candle lamps; first, on the hypothesis that it shall always be ready to supply the 40,000 lights at half an hour's notice, day or night, but that the lights are hardly ever required; secondly, on the hypothesis that the 40,000 lights are steadily and continuously supplied, day and night. These, of course, are the two extreme cases possible. In the former the load factor is nil, while in the latter it is 100 per cent. If the charge is by meter at 8 pence per kilowatt hour, in the former case the revenue will be nil, and in the latter case it will be £730,000 a year.

Dr. Hopkinson then divides the cost of supplying electricity into two parts—a charge which is independent of the hours the supply is used, and a charge which is directly proportional thereto, and estimates each amount accordingly. To provide the maximum of 40,000 lamps requires an estimated outlay of £145,000. The fixed charges, including interest, taxes, depreciation, etc., would amount to £16,410 running light, and to £18,750 fully loaded. Coming to the most important item, the coal account, and adding it to the previous items, we get at the charges for running light, and fully loaded, viz.: £28,010 and £59,250 respectively. Thus, as Dr. Hopkinson shows, the cost of being *ready to supply* current for 40,000 lights at any moment throughout the year would be £28,010, whereas the cost of *actually supplying* the amount of current required for every minute in the year would be £59,250.

Based upon these figures, Dr. Hopkinson points out what he had already urged on the Board of Trade committee in 1883, viz., that a differential charge ought to be made to consumers, giving the benefit to those who used current during light load hours, and thus affording a revenue during hours of comparatively high running expense to the central station. Dr. Hopkinson has also prepared a chart comparing the charges at a fixed rate per kilowatt hour, and what he terms a "compound" rate which involves a certain fixed charge whether the current be used or not, and an added light charge for the amount of current actually consumed. This chart shows that for anything over 500 kilowatt hours, the compound charge is more economical to the consumer than the simple flat rate, and this gain in his favor increases rapidly with the increased use of the current. The curve also shows the enormously decreased cost of production with a heavily loaded station as compared with a lightly loaded one. In this connection, it may be pointed out that many American central stations might be said to charge a compound rate in that they have increased rebates with increased use of current by consumers, by which practically the same end is reached.

Thus far Dr. Hopkinson's calculations assume that the supply of electricity is carried on without the aid of accumulators. In view of the neglect of these adjuncts to central stations in this country, it is of special interest to follow his calculations regarding them. In order to show first the difference in the nature of storing electrical energy as compared with the problem as presented to the gas companies, Dr. Hopkinson shows that a gas holder of 7,000,000 cubic feet capacity, such as is now being constructed in Manchester, England, will cost £60,000, and 7,000,000 cubic feet of 16-candle gas are equivalent to 56,000 kilowatt hours. The accumulators capable of storing 10 hours' supply cost about £50 per kilowatt hour, so that the equivalent battery would cost about £280,000. The latter item does not include the allowance which must be made for renewals and repairs; also the further allowance due to the fact that while the gas holder gives back all the energy given to it, the accumulators may be assumed to waste 20 per cent.

Taking up the cost again of an assumed station with 40,000 lights, with accumulators capable of supplying a continuous maximum demand for ten hours, a battery would cost £62,500, and to maintain it and to allow for depreciation, would involve a fixed charge of £12,500 for the batteries alone. The battery, of course, if distributed at various points, would allow the boilers, engines and dynamos, etc., to be reduced one-half, and the conductors correspondingly, since smaller and shorter feeders would be required. The wages also could be reduced. Taking all things into consideration, Dr. Hopkinson arrives at the figure £28,105, as the cost of operating such a station with storage batteries. Curiously enough, this figure is practically the same as that for operating the station without storage batteries, but running light. Thus, in a station of the size assumed, the cost of being *ready* to supply, and to *continue* to supply, is about the same whether accumulators are used or not. The additional cost of actually supplying current is about 40 per cent. more, in the case assumed, where accumulators are used, than where they are not used.

In making this calculation Dr. Hopkinson, of course, takes the accumulator as he finds it, but he is careful to point out that a very little improvement in the cost, durability, and efficiency of accumulators would render them valuable even in very large stations for the mere purpose of diminishing the machinery required. The certainty that accumulators would be improved in time, and largely so, appears to him a strong argument for the use of the direct current, wherever the distance over which the current is to be conveyed is not too great. He also lays special stress on the fact that this calculation is based on the assumption of a very large station, and he does not hesitate to say what has already been, we believe, practically demonstrated, that in most small stations giving a continuous supply, accumulators ought to be used, notwithstanding their expense and defects. Dr. Hopkinson goes so far even as to assert that, in the not very distant future, accumulators will be used in connection with most large stations also.

In considering the employment of alternating currents with transformers, a modification in the calculations would naturally be caused for conductors principally, but on the other side of the balance sheet, would be the cost of the transformers. If the distance were small, increased cost of transformers will exceed the saving in conductors, and vice versa. In both cases the general character of the result will be the same as before, viz., that the cost of being prepared to give a supply will be considerable, and the cost of actually giving the supply will be much smaller than is generally supposed. Dr. Hopkinson concludes that to be ready to supply a customer with electricity at any moment he wants it, will cost those giving the supply not much less than £11 per annum for every kilowatt hour, which the customer can take if he wishes; and afterwards to actually give the supply will not cost very much more than ½ penny per kilowatt hour. This is a very interesting result, and its application to the method of charging customers ought to be closely studied by all central station managers. It will be noted that in the above calculations Dr. Hopkinson has not taken into consideration the question of supplying current for electric motors, which, so far as this country is concerned, is a source of revenue, practically not calculated upon abroad; and as the rates for power per kilowatt hour in the United States are greater than those obtained for the same amount of current when used for lighting purposes, a considerable modification in the calculation would be introduced.

OPENING THE WORLD'S FAIR AT NIGHT.

The question of opening the World's Fair at night has continued to be the subject of agitation and discussion. The management of the Fair, having been invited to reconsider the rule closing the grounds every night at 7 o'clock has done so, but its statements as to a possible opening two or three times a week are regarded as vague and unsatisfactory. What is wanted, and should be given, is an assurance that a portion of the grounds and some of the buildings, will be open regularly at night, including such buildings as Electricity, Fine Arts, etc. The matter has been taken up by the newspapers, and in New York, the *Tribune* and the *Sun* have both expressed themselves in favor of night opening. In view of the immense success of night opening at Paris, in 1889, there is every reason to believe that regular night opening at Chicago in 1893 would be very successful and a great boon.

THEORIES OF SECONDARY BATTERIES.

There is something very attractive, says *Industries*, about the theory of the lead secondary battery, and the subject seems to be a happy hunting ground for scientists afflicted with theories. The conversion of sulphate of lead on both plates to lead on one and peroxide on the other during charge is simple, but it leaves no scope for wild originality. We have, therefore, to put up with all kinds of ridiculous theories—such as those of occluded gases, formation of litharge, and others more complicated. The latest addition hails from the Continent. We are now told that, on charging, sulphate of lead is reduced to sulphide, and the E. M. F. is due to the laudable but eccentric desire of the sulphur to jilt the lead and take up with oxygen to form sulphuric anhydride. We wonder whether this theorist thinks that carbide of lead is formed when carbonate of lead is reduced in a solution of carbonate of soda.

LIVERPOOL OVERHEAD RAILWAY.

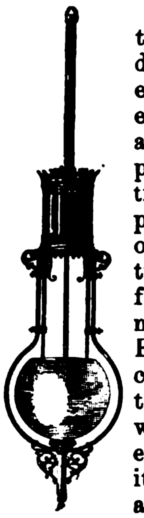
The first train was run on this railway on November 7, carrying the directors and their friends. The trip was satisfactory, the behavior of the generating engines and dynamos being all that was anticipated. There were present the chairman of the Railway Company, Sir William Forwood, and the whole of the directors; Mr. J. H. Greathead and Mr. Francis Fox, the engineers.

Ball Dynamos, and How They Are Made.

BY

Leslie W. Collins

I.



Ball Lamp.

The appearance at the Philadelphia Electrical Exhibition in 1884 of the Ball unipolar dynamo—a machine with two armatures each exposed to a single pole—created one of the most exciting and interesting controversies that ever arose in the field of arc lighting. It was persistently urged by many, including authorities of note, that such a machine could not possibly work; but as it was seen in steady operation for several weeks without interruption, the criticism fell rather flat. It was further objected that the machine, if it ran, must prove very inefficient; but the well-known Franklin Institute tests did not bear out the contention, the only report obtainable after the five days' trial to which the Ball dynamo was put being one that established a high efficiency of conversion—so high, in fact, that it outranked many be-lauded competitors. The arc lighting industry has seen many changes since that time, but the Ball unipolar machine has survived them all, and is to-day the basis of a large and prosperous electrical industry, which has just completed its decade, and of which, therefore, some account will be of more than usual interest.

The foundation of the industry was due to Mr. Charles E. Ball, a mining engineer, who, prior to 1880, had taken a deep interest in electrical development, and who, being a man of great inventive genius, had devoted a large portion of his time to the perfection of electrical apparatus for the mining and reduction of ores. He is in reality entitled to the credit of being practically the first mining engineer in America to appreciate the full importance of the changes that electricity was about to cause in the mining industries of the country. In 1880 he made his *debut* as an electrical mining inventor, and produced an electrical plunger and rock drill. But, as we all know, the time was hardly ripe for such things, and a man so far advanced in his ideas passed not merely for an enthusiast but for a fool. He was not intimidated or discouraged, however, but belonged to the class of Maxim, Fuller, Sawyer, Van Depoele, Westinghouse and others, who were attracted from mechanical inventions and mechanical interests by the evidence of great opportunities in the domain of electric lighting; and it was there that he now proposed to concentrate his energies. To this end, he began at once, and very naturally, the construction of his own dynamo. In those days, the ideas of electro-dynamic generation were still very vague, as applied to arc lighting work, and sad havoc with machines was the result. Large dynamos that would operate a long circuit of arc lights in series, without committing suicide in the process, as the result of their own high tension, were very much in demand. Mr. Ball had an idea that the use of two armatures connected in series, each taking its share, would overcome the trouble, and on these lines he constructed his first machine. It did not quite realize his expectations, so he went at it again. After his modifications had been carried out, the machine was reassembled, and a great transformation resulted. Whereas the machine had previously run hot, its armatures were now perfectly cool, and the output was vastly larger, for much less power applied to the pulley. The most striking singularity of all,—half accidental it might be considered,—was that while there had formerly been four poles, or two for each armature, there were now two, placed diagonally across the machine, or one only for each armature. This was the origin of the now celebrated Ball "uni-pole" machine, around whose youth such fierce battle waged, when its originality of design challenged the criticism of the world. As might be expected, the oppo-

Royal E. Ball.

sition of experts and theorists, many of whom stood very high, had its effect, and the progress of the machine was slow. But it still did make headway, as a commercial enterprise, on the ground of its high economy, and Mr. Ball persevered in the development of other parts of the system. In 1882, the experimental work and investment of himself and associates were acquired by the Ball Electric Manufacturing Company, which organized under the laws of Pennsylvania, with a capital stock of $200,000.

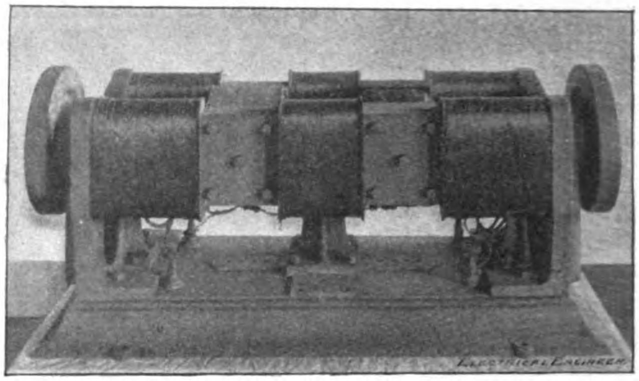
II.

It was thus that ten years ago the Ball dynamo entered a field where demerit is fatal to long-continued existence; and the demand for a machine from which, if needed, two independent circuits could be run, at once became active. Mr. Royal E. Ball, a brother of the inventor, and a civil engineer, graduate of the Rensellaer Polytechnic Institute, of Troy, became identified with the company, as its electrician. A small factory was started at Reading, Pa., and an experimental shop was kept busy in New York City. The first dynamo built by the company for sale was sold for an electric light plant in Mexico, and the first central station on the Ball system was put in operation at Scranton, Pa. That is a long time ago, as electrical history and development run, but it is worthy of note that those first machines are still in active use, giving excellent results; from which it may be inferred that the electrical and mechanical details of the system had been early perfected. The business of the Ball Electric Manufacturing Company was not extensive, but from the very beginning the system stood on its merits, paid its way, and gathered some little surplus.

Charles E. Ball.

III.

As has already been stated, the Ball system was placed on view, in operation at the International Electrical Exhibition of the Franklin Institute, in Philadelphia, in 1884, and at once attracted the greatest attention. A great many other arc machines were there, of more or less merit, but it is safe to say that none was so often or so critically inspected as the Ball, from which a number of lights were run every night. When the International Electrical Congress convened during the exhibition, and the subject of dynamo-electric machinery came up, it was the Ball machine that again came in for an undue share of attention. One of its sharpest critics on the floor of the Congress was Prof. Silvanus P. Thompson, who did not hesitate to reiterate his derogatory opinions later on in the earlier editions of his great volume on "Dynamo-Electric Machinery," the standard book on the subject. But mere criticism can never kill a good thing, and recognition will come, even if tardy. Mr. Ball has therefore had the satisfaction of seeing that while Prof. Thompson, with an Englishman's tenacity, is slow to give up his views as to the correct theory, he is compelled to admit the practical merits of the Ball "unipole" machine, for his last edition (page 477) says: "It remains, however, to be stated that in spite of these imperfections of design, *the Ball machine has given great satisfaction, its construction having evidently been carried out with good engineering skill.*" The proof of the pudding, if we may believe an old adage, is in the eating. The Ball machine is one of the few that have survived the stress of time and progress, and one of the few which, seen at Philadelphia in the Electrical Exhibition in 1884, will go with colors flying and the trophies of victory to the Chicago Exhibition of 1893.



FIRST BALL DYNAMO, 1881.

IV.

To complete the historical sketch that has been given of the development of the Ball system and industry, it should be mentioned that in 1886, the interests of the Ball Electric Manufacturing Co. were bought out by a corporation formed under the laws of New York State, called the Ball Electric Light Co. A factory was thereupon established in this city, on Second avenue. The business of the new company increased so rapidly that it soon became evident that larger and more desirable quarters must be moved into without delay. To this end the company secured early in the year 1886, a large four-story manufacturing building on the corner of Ninth avenue and Twenty-seventh street, where it is still in occupation. This desirable building has a frontage of 200 feet on Twenty-seventh street, and 100 feet on Ninth avenue, the location being on a corner, insuring perfect light, ventilation, etc. Nearly everything necessary for the establishment of a first-class manufactory was already there,—for instance, a large battery of first-class boilers, Corliss engine plant aggregating over 150 h. p., freight elevators, and in fact everything needed to start at a moment's notice. Once in this building with the admirable facilities at hand, the company was in a position to

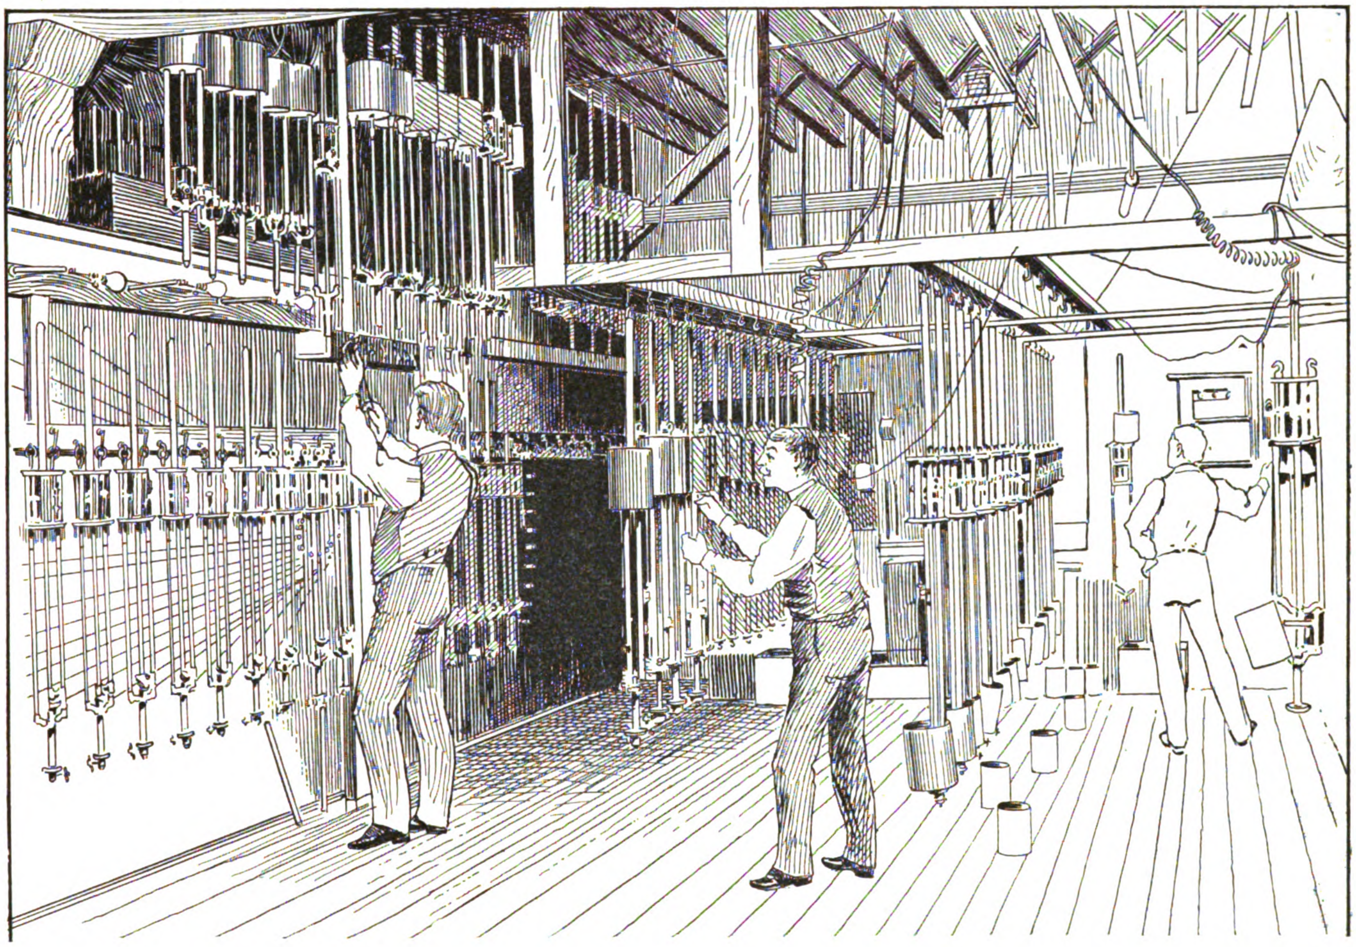
W. A. Nicholson.

accept and fill without any delay all orders for apparatus with which it was intrusted, and thus entered on its present career.

V.

Coming to a brief description of the factory before passing on to the apparatus itself, I would remark that electrical factories such as this is are rare examples of steady application to the production of one thing. Passing in at the main entrance, which is located on the Twenty-seventh street side, we proceed to the third floor. This may, in reality, be called the main floor of the factory, as on it is located a desirable suite of offices. A partition running along the north or Twenty-seventh street side affords an allotment of space for the said offices, which combine general, private, and managers' offices. The office of the superintendent Mr. W. A. Nicholson is also on this floor, as most of his time is spent here. This floor, as our illustration shows, is very large, being an entire open floor of the building 100 by 200 feet, and contains the large lathes, planers, turning and boring machines necessary in the construction of the dynamo. The assembling department is also on this floor with a convenient testing room close at hand. The assembling room occupies a desirable space in the centre of the main floor within easy reach of the machine department. The illustration of this room gives a good idea of a number of the Ball dynamos in waiting for the armatures, and final connections. We are afforded here an excellent opportunity of inspecting freely and closely the Ball automatic regulator, and the special automatic machine, the regulating part of which is entirely self-contained. This last machine is claiming a great deal of attention just at present, and the Ball people believe that they stand first in the field with this particular type of dynamo.

The Ball Company manufacture also all the arc lamps for use in their system, and have a splendidly equipped department, occupying a space of one of the floors of the factory about 70 by 70 feet square. This room, facing as it does on the north of Twenty-seventh St. and on the West on Tenth avenue, gives the workmen what is most needed in the construction of the more intricate parts, that is, excellent light. This portion of the factory is capable of turning out over forty complete lamps every day. On this same floor is located a well-adapted armature-room, having a number of large windows on two sides, giving excellent light and ventilation. There is ample room in this department for at least fifty trusses or stands for armature winding. The testing-room, still another important department, is also located on this floor, and is one of the most complete departments in the factory. It is here illustrated. This room is an adjoining one to the lamp manufacturing department, and has a capacity for the hanging and testing of about 200 lamps at one time.

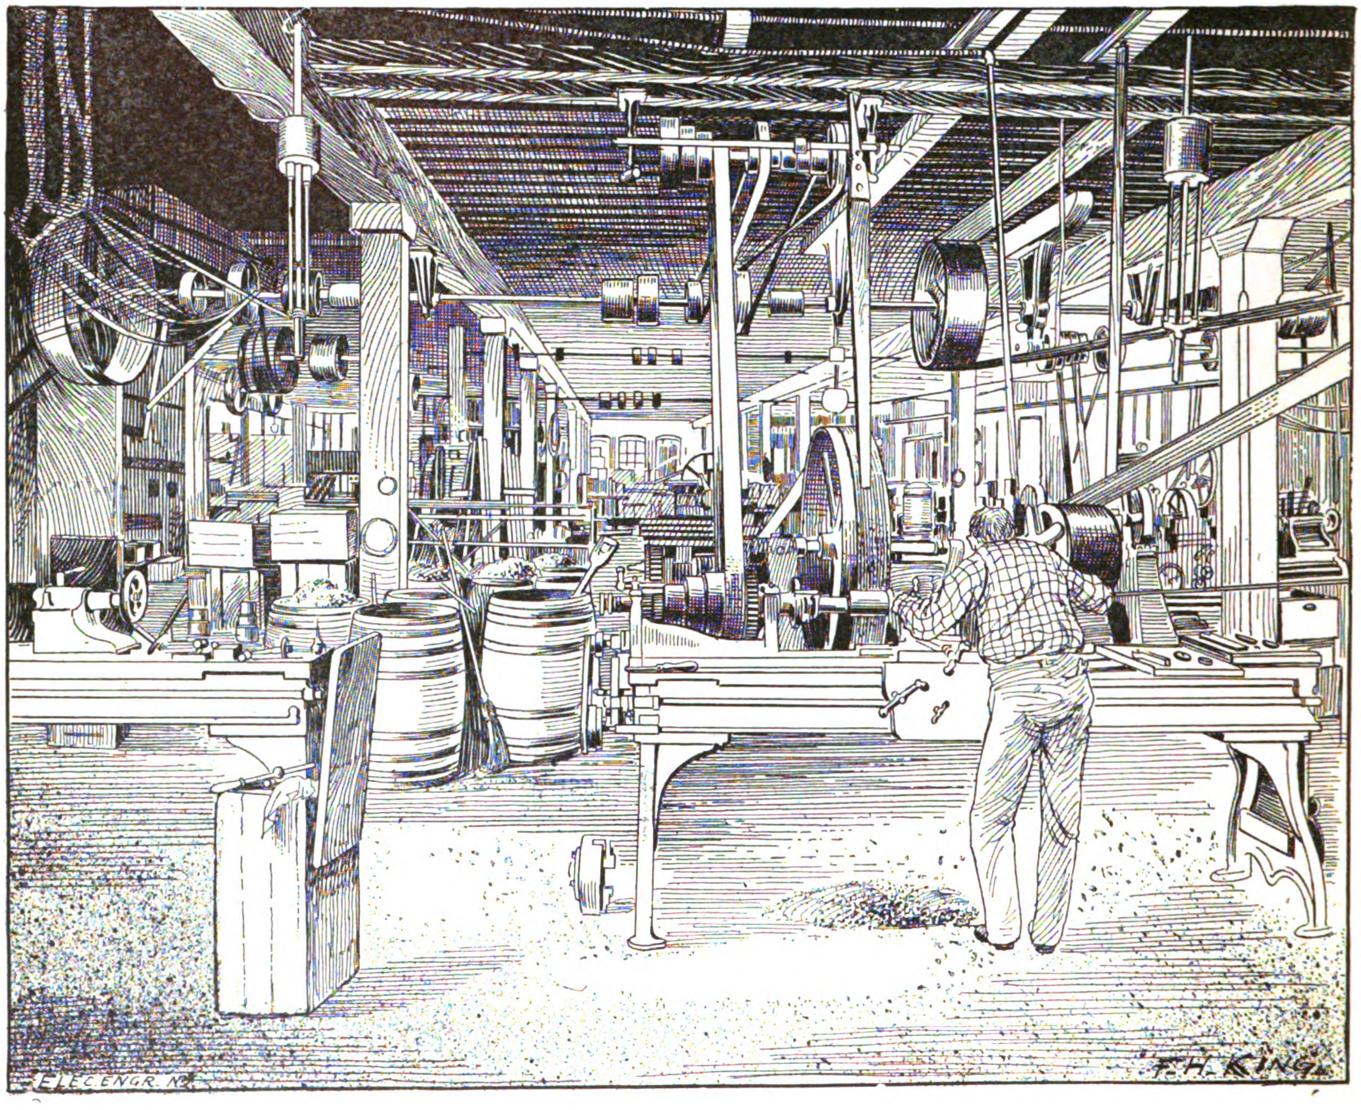


In the Lamp Testing Department.

A most novel and interesting lamp has recently been placed upon the market by the Ball Electric Light Co., and may be here spoken of. It is an all-night lamp, with a reciprocating carbon attachment. This lamp has all the familiar advantages, it is said, of the double, triple, and disc carbon lamps, but at the same time is entirely free from the unreliability of complicated mechanisms. To obtain the protracted burning, an attachment is placed upon the regular Ball arc lamps, which produces the swinging or reciprocating of the top or positive flat carbon across the lower or round carbon, the former being made with a greater cross-section than the later. Thus, as the upper carbon wastes away and is fed to the arc it is periodically fed across the arc so as to consume one portion after another. The illustration of this particular lamp which we present is so nearly perfect as to be almost self-explanatory.

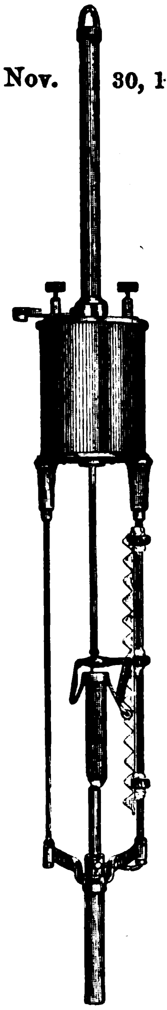
VI.

Like all of its competitors, the Ball dynamo was, no doubt, a little crude at first, but as improvement has been the all-important point in the development of electrical interests, the Ball Electric Light Company have kept abreast of the times, and have from time to time added perfections and left out discovered imperfections in their dynamo, so as to have a machine which could be classed second to none at present manufactured.



Vista of the Main Machine Shop, Ball Factory.

The Ball machine during all these years has gained its reputation and business on its merits as a dynamo. Until recently the company have refrained from the manufacture of a dynamo having automatic regulation, their claim being that their dynamo without an automatic regulator was superior to any dynamo with it. In order to enlarge its range of manufacture, and to meet the wishes of those who wanted machines with automatic regulation, recently the Ball Company have perfected and are now placing on their dynamo an automatic regulator of new and novel construction. By reference to the illustration of the Ball dynamo with automatic regulator, it will be seen that the armatures each revolve in proximity to a single pole piece, leaving one-half of the armatures as exposed parts. An armature in answering its purpose as a generating device is, at the same time, to a certain extent at least, a magnet having its field of force responding to the rising and falling of the main current through the armature. A small magnetic bridge is placed over the exposed parts of one of the armatures as an external magnetic circuit between the two poles of the armature. By a combination of levers, this bridge is connected to a step-by-step motion which operates the brush-holding yoke and moves forward or backward according as the field of force of the armature varies from the rising or falling main current flowing through it. It can be seen by this short description that the Ball Company have a simple, uncomplicated and what should be, a positive regulator. Not content with this, however, they have gone beyond, and have perfected and are placing on the market a self-contained, automatic dynamo. It is simply a trifling modification of the regular Ball dynamo. The automatic feature or principle is at once self-contained and without external mechanism or complications whatever. Trifling changes are made in the shape and size of some few of its parts. The yoke or brush-carrier is made of a magnetic material, and extends backwards in the shape of a disc to fit loosely into a cored-out part of the end frame.



Ball Reciprocating Lamp.

Thus, the yoke is at the same time a brush-carrier and a movable part of the main magnetic circuit. This yoke is supported by ball bearings and is so constructed as to have two axes of different magnetic reluctance and at right angles to each other. Of course, the tendency of the yoke is to set itself with the axis of least magnetic reluctance parallel to the magnetic flow through the end frame. This tendency is counter-balanced by the proper disposition of weight (see illustration of the "Ball Automatic Dynamo"), and accordingly the yoke with its brushes responds to changes of magnetic flux, thus maintaining a constant field and current. Its action is direct, positive and instantaneous from full load to no load.

VII.

The Ball Company continue to pay especial attention to their 800 c.p. arc lamps, which have a consumption of four amperes and an E. M. F. of 49 volts, and they maintain their claim to give over three lights per horse power. This the company believe due to their double armature and the finer or high tension winding. The double armatures actually produce two currents or circuits, thus dividing the tension and necessarily the load, whereas in other machines the one armature is compelled to bear the whole load. This, at any rate, is no experiment with the company, as they have been selling the four ampere system for six years and undertake to guarantee the above results to purchasers. The Ball Company have also just completed what is asserted by them to be the largest arc dynamo ever built. This machine has a capacity of 120 full 2,000 c. p. lamps. The machine is, of course, a regular Ball two armature machine with the self contained regulating device. It is practically a two circuit machine with 60 lights on each circuit, and being automatic at both ends, permits, in case of any posible accident to either armature, the running at a high speed of the uninjured one, thereby insuring a capacity under these conditions of at least 90 lights. This machine has 3,000 volts on each circuit consuming ten amperes. The facilities of the company at the present time are such that almost any sized machine and its regular complement of lamps can be secured within at least thirty days' time.

VIII.

In closing my article, I should add that the Ball Company have manufactured and sold a good many 8 and 10 ampere dynamos and lamps, additional to those of which I have ventured to give a more detailed description. They have also had occasion to supply frequently their Ball series system for long-distance incandescent lighting, and have now upwards of 10,000 such lamps on Ball circuits in this country, Canada, Mexico, Central America and South America.

At the present time the affairs of the company are managed by W. L. Brown, president; Chas. E. Ball, vice-president and general manager; R. E. Ball, electrician; Geo. R. Cullingworth, treasurer, J. S. Bell, secretary, and W. A. Nicholson, superintendent. Of the latter gentleman I have also given a vignette portrait, and I wish to take the liberty here of acknowledging the many courtesies received at the hands of Secy. J. S. Bell, Supt. Nicholson and the Messrs. Ball, in my inspection of the factory and the apparatus.

ELECTRIC RAILWAY DEPARTMENT.

THE NEW RAE CAR MOTOR EQUIPMENT.

BY

Frank B. Rae

SOME four years ago at Elkhart, Indiana, the first attempt was made to equip a street railway with single motors geared to both axles, the plan proposed by the writer being one in which a rigid frame supporting the motor and countershaft was carried upon the axles, and the power transmitted by bevel gearing from the countershaft to the car axles. This method of applying the power was criticised, particularly by the builders of two other motor systems, who predicted failure on account of the rigidity; but the advantage of a single motor driving both axles seemed sufficiently great to warrant a thorough test, and some forty roads equipped with the Rae system demonstrate the success of the single motor. Extreme rigidity of the motor carrying frame and perfect alignment is necessary to keep the bevel gears in proper mesh; at the same time sufficient spring in the whole arrangement must be allowed to avoid lifting one wheel of the truck on curves, and when this condition is not exact, broken gears and other troubles immediately ensue.

To more thoroughly overcome the difficulties and objections to the rigid method of driving both axles from a single motor and at the same time obtain the advantages of flexibility claimed by employing a motor on each axle the writer has brought out the arrangement illustrated below. While the bevel gearing has been adhered to, all the other features of the Rae system familiar to the readers of this journal have been greatly modified.

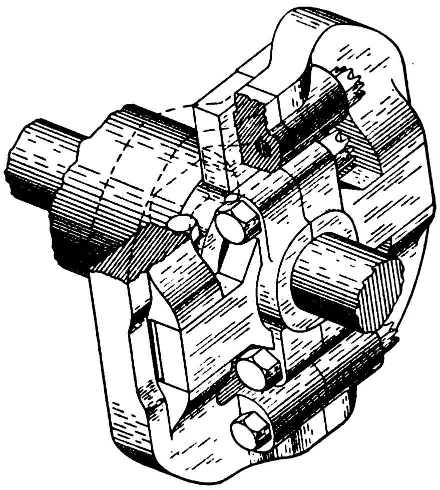


FIG. 3.—FLEXIBLE COUPLING, NEW RAE CAR MOTOR.

The frame heretofore used has been dispensed with, and the motor itself forms the frame and is directly supported on the axles, as shown in Fig. 1, which represents a plan view of a 40 h. p. truck equipment. The countershaft is dispensed with, the motor being of the slow speed type and geared direct between the armature shaft and car axles. At one end the bevel gear is directly upon the axle, while at the other it is mounted upon a sleeve or quill in bearings which are a part of the motor frame. This quill end of the motor frame rests upon springs, which relieve the motor greatly of jar and consequent crystallization, and permit the axle within the quill to take any position without putting any twisting strain upon the motor. This construction is seen in Fig. 3.

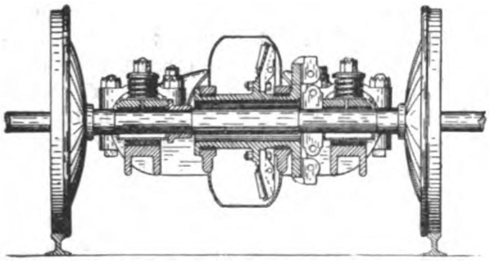

Fig. 4.—New Rae Car Motor—End View.

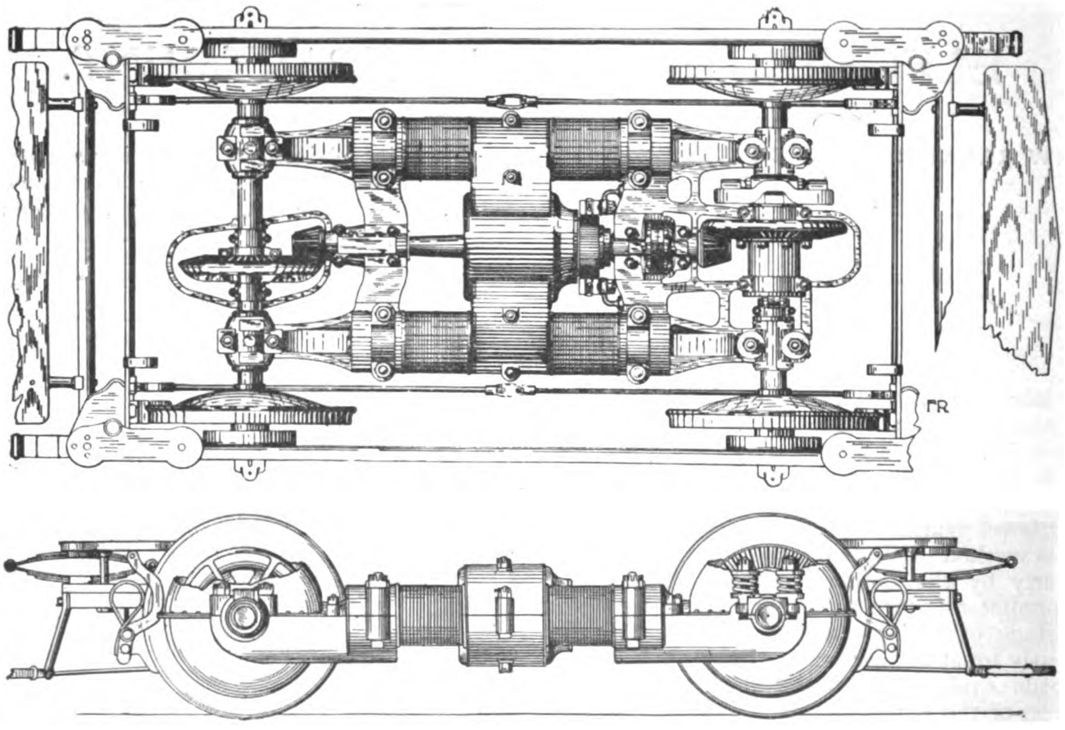
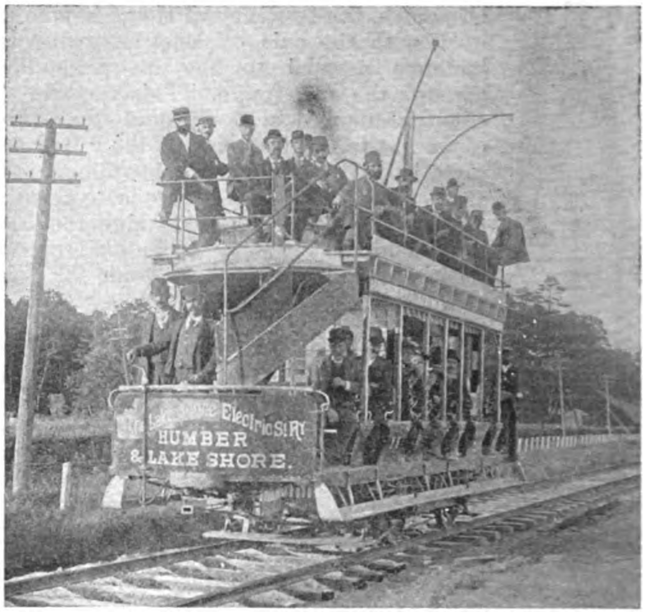
The power is transmitted to this axle by means of a flexible coupling between the quill and axle, and will be understood by reference to Fig. 3, which is an isometrical drawing of the coupling. This device consists of three parts, the first being clamped to the axle and provided with two projections which fit loosely into recesses in the second part. Upon the quill is clamped a piece with two projections similar to that upon the axle, the projections also fitting into the second part, but at right angles to the other. It will thus be seen that the axle may take any position in relation to the quill and still drive without altering the angular velocity between the quill and axle and without cramping the motor frame or affecting the gears; the work upon the gears being in proportion to the duty at any point of rotation.



Figs. 1 and 2.—New Rae Single Reduction Car Motor.—Plan and Side View.

Upon the rear axle, or the one to which the gear is directly attached, the motor bearings are held from movement endwise by a thrust bearing formed directly upon the axle, similar to that used upon propeller shafts, which effectively prevents any shifting of the motor upon the axle.

The field magnets of the motor are of round wrought iron to which the pole pieces, each formed of two parts, are cast and bolted to the field pieces. The magnet yokes which also form the supports upon the car axles as well as the boxes for the armature shaft are in one piece. This construction reduces the entire motor to eight distinct pieces plus the armature and gears. These eight pieces are put together with 12 bolts, and the locked nuts for these bolts are all upon the top and accessible through the traps of the car. As will be seen by the side elevation, Fig. 2, the clearance between the motor and ground is greater than in other single reduction equipments.



Double Decked Car with Rae Motor Equipment.

The electrical design of the motor has been carefully worked out, the efficiency agreeing with that of the best design. The motor proves upon extreme work to be absolutely sparkless with any load. The rise in temperature in field coils, armature and commutator is hardly perceptible after a full day's duty. Contrary to the usual practice of rating street car motors, this equipment is designed to furnish its full rated horse power continually and not intermittently.

The first road to equip with the new Rae system is the Toronto & Mimico Electric Railway, a suburban line along the lake shore near Toronto, Ontario, operating only during the summer months. Double deck cars are used which are mounted upon McGuire trucks.

RAIL BONDING AND MEASURING GROUND RESISTANCE.

BY

Franklin Sheble

Electric railway engineers must have read with interest the article on "The Resistance of Return Circuits," in The Electrical Engineer of Nov 9. In it Mr. Warner has brought out fully the importance, and even the necessity, in roads of average size, of relying on the rail as a conductor for the return current, rather than laying expensive supplementary wires for this purpose.

In using the rail, the important question is—How to secure good bonds between the rails? The bonds connecting the rails must be of sufficient size to carry the total return current in case one of the bonds on the opposite rails should loosen or break. The bonds joining the rails of a single track road should be cross-connected at each joint, and if the road is double track, the two tracks should, in addition, be cross-connected at every 500 feet, or oftener, according to the amount of traffic.

It has recently been proposed to use a galvanized iron cable, about three feet long and ¾ inch in diameter for bonding rails. This should be carefully connected to the rails; a good way is to use a split plug, and drive the plug, with the cable in the centre, into a hole in a web of the rail, care being taken that all surfaces are bright.

The use of iron for bonding rails has been objected to, on the ground that it will corrode and be eaten away more rapidly by electrolysis. If the iron cable proposed is galvanized, and if the cable and the joints are well coated with pitch or asphaltum, the life of the bond should be as long as the life of the rail.

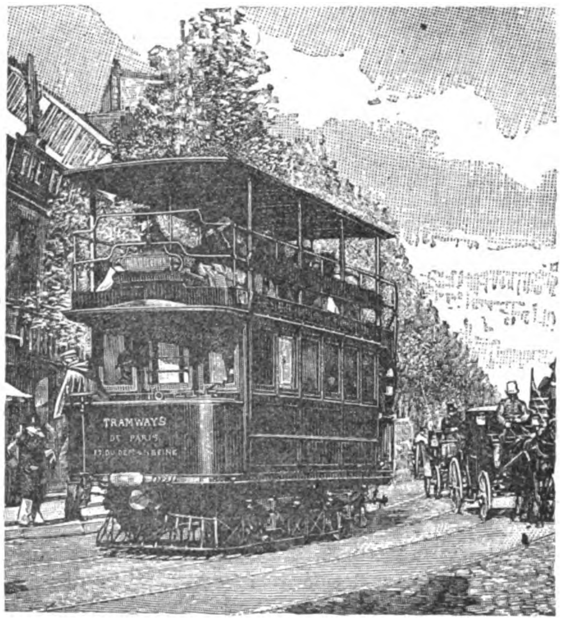
In the paper referred to, Mr. Warner used the top wire of a barb wire fence for the potential wire. I would suggest that one of the guard wires be used for this purpose. I have measured the resistance of the ground circuit in the same manner as given in the article mentioned, with the exception that a motor car and trailer were run out on the road after all the other cars were in for the night. Through the kindness of the local telephone company, a direct connection was made from a subscriber's telephone along the road through the telephone exchange to the power station. A connection was made from the line side of the subscriber's telephone through a high resistance voltmeter to the rail, and from the line side of the telephone at the power station to the ground side of the generators. The connections through the central exchange was made from line to line. These connections were made for five minutes and then disconnected, in case any one wished to telephone to either party, and made again, until perhaps a dozen readings could be taken. The brakes were set on the cars, current put on the motors, and ammeter and voltmeter readings taken. Simultaneous readings were taken on the instruments in the car and on the voltmeter in the rail circuit. The voltage at the power station was kept constant. The difference between this voltage and the voltage around the motors gave the drop in both line and rail circuits. The difference between this and the drop in the rail circuit gave the loss in the line. The resistances of the line and rail circuits are determined, knowing the current. In this way the resistance of the line and rail circuits can be determined at different points along the route of the road, at any distance from the power station.

The importance of having private telephone lines run from the power station to different parts of the city, in case of accident on the line, has often been brought up. These same lines can easily be used as potential wires at different times during the day, and the drop in the rail or line circuits read at the power station. Connections can be made from the telephone stations through a portion of the guard wire to other sections of the line or rail, and by this means the drop in the different circuits can be determined exactly, and copper added to the line, or grounds added to the rail, as conditions require.

STORAGE BATTERY CARS IN PARIS.

As already announced by us, the Compagnie des Tramways de Paris et du Department de la Seine have recently put into regular operation storage battery cars on their line running from the Madeleine to Saint Denis. A view of one of these cars, taken from *La Nature*, is shown in the accompanying engraving. It has seating capacity for 56 persons, and is double decked. The storage battery charging station is situated at Saint Denis, and the current is furnished by two Desroziers 60 kilowatt-machines running at 600 revolutions, and furnishing 200 amperes at 260 volts. A third dynamo of like capacity is kept in reserve.

The accumulators employed on the cars are manufactured by the Société Anonyme pour le Travail Electrique des Metaux and are of the Laurent-Cély type, built at the works of the company at Saint-Ouen-les-Docks. They consist of 11 lead plates, 200 mms. square, and have a total active surface of the positives of 40 square decimetres. The external dimensions of each accumulator are 37 cms. high, 37 cms. long, and 23 cms. wide. The normal charging rate is 17.6 amperes, and the maximum 35.2 amperes. Under the same conditions the discharge is 26.4 and 52.8 amperes. The available capacity is 264 ampere hours at normal discharge, and 158 at the maximum. The accumulators are placed in wooden boxes, 9 in each box, and 3 boxes constituting one battery. Each car carries 4 batteries of 3 boxes, thus making 108 cells to the car.



TRAMWAYS
DE PARIS
ET DU DEPT DE LA SEINE

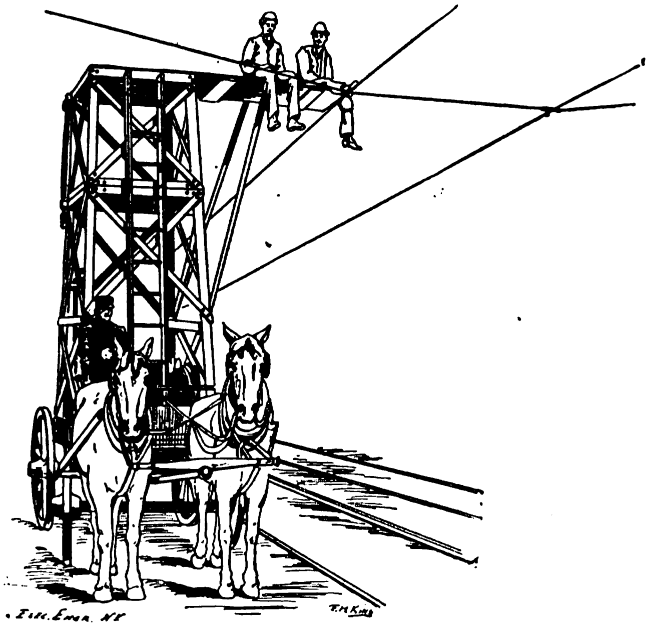
A Paris Storage Battery Car.

The motors are designed to operate at 200 volts and 50 amperes running at 1,300 revolutions per minute, which is reduced by gearing at the car axle to 108 revolutions per minute. The usual switch is provided for connecting batteries in various combinations for obtaining the different speeds required. Within the city of Paris a speed of 7½ miles per hour is permitted, while beyond the fortifications 10 miles per hour is allowed.

THE PETERSON TOWER WAGON ON THE MONTREAL STREET RAILWAY.

BY L. M. PINOLET.

It is necessary that the tower wagons at present in use for street railway construction or repair work should stand directly under the wire at which the men are working and, consequently, when such a wagon is employed for work on a trolley wire it must stand on the track and whenever a car passes the men have to stop their work while the wagon is hauled to one side to allow the car to go by. These interruptions interfere with the work of the men and if the cars pass frequently, cause a considerable loss of time.



PETERSON TOWER WAGON ON THE MONTREAL STREET RAILWAY.

To obviate these delays, the Montreal Street Railway Company in the introduction of the trolley system on its lines, is using most successfully an ingenious and simple extension tower wagon designed by Mr. A. Peterson, lately with that company. This wagon differs from the ordinary tower wagon in being provided with an extension, and when used for work on a trolley wire stands at one side of the track where it is out of the way of the cars, and thus the men can work without interruption, as this wagon does not have to be moved from its position to allow a car to pass.

As appears from the illustration, which shows two men at work on a wire, the cars can pass meantime on the track beneath. This wagon and its tower are like those in general use, but are of a somewhat heavy construction in order to secure stability. The tower at its base is 6 feet by 4½ feet, and at its top is 3 feet 3 inches square. The total height from the ground to the top of the tower is 16 feet. The extension is a light wooden platform, 5¾ feet by 3 feet projecting over the track sidewise to the tower, to which it is attached by two iron hooks that catch in rings on the top of the tower. Two wooden supports serve as brackets to sustain the extension in a horizontal position and are provided at their upper ends with hooks that catch in rings near the outer edge of the platform and at their lower ends have iron tongues that fit in rings on the tower near its base.

The extension can be folded up against the tower, by lifting the tongues out of the rings, lowering the platform and then detaching the supports by unhooking them, when the extension will hang down close against the tower. It can be removed entirely by simply unhooking it from the rings in the top of the tower and, in the same manner, may be put up at the other side of the wagon where rings are provided for this purpose.

AN ELECTRIC RAILWAY PROJECT AT INDIANA, PA.

MR. JOHN L. PAUL, the secretary of the Indiana (Pa.) Electric Company, writes us as follows: "The matter of building an electric railway 28 miles long between this town and Punxsutawney, Pa., is being discussed, and we invite interviews with electric railway people to this end. The proposed line would pass through a very good farming district and would tap about six small towns not now having any railway facilities whatever. It is believed that the matter of freights would alone be enough to warrant the building of the road without taking the passenger traffic into consideration. The writer of this can be addressed in regard to it and will give all the information in his power, and will, if desired, go over the proposed route with railway people."

MISCELLANEOUS.

THE PARSONS CONDENSING STEAM TURBINE.

PROF. EWING, of Cambridge, England, has just made public a series of tests conducted by him last August, upon the Parsons condensing steam turbine, using moderately superheated steam, by means of which very remarkable results are obtained.

TABLE I.

Trials with Continuous Current Armature, with Steam Superheated by the Gases from the Boiler Fire only.

Pressure by gauge on boiler, lbs. per sq. in.	Temperature of steam, ° Fah.	Load in electrical units per hour.	Feed-water per hour in lbs.	
			Total.	Per unit.
96	335	0.1	480	—
102	365	10.2	760	74.5
100	356	27.0	1110	41.1
102	400	49.2	1590	32.3
100	390	74.5	2170	29.1
103	398	102.0	2900	28.4

TABLE II.

Trials with Continuous Current Armature, with Extra Superheating.

Pressure by gauge on boiler, lbs. per sq. in.	Temperature of steam, ° Fah.	Load in electrical units per hour.	Feed-water per hour in lbs.	
			Total.	Per unit.
102	463	28.3	1060	37.5
102	468	49.5	1480	29.9
101	465	78.4	2170	27.7

The dynamo tested was one of the type shown in the accompanying illustration, Fig. 1, for which we are indebted to our contemporary, *Lightning*, which represents an actual machine destined for the central station at Cambridge. It was primarily constructed to generate alternating current up to 50 amperes, at a potential of 2,000 volts, but in order to put the electrical measurements beyond range of dispute, a continuous current armature, giving 400 amperes at 250 volts, was specially wound for these tests as well, the results obtained with the two armatures being afterwards found to correspond closely.

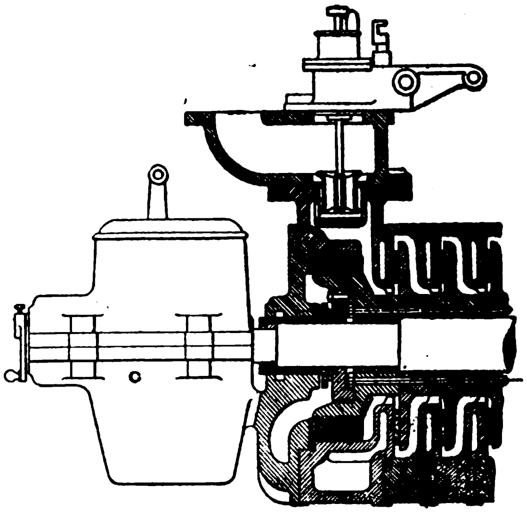


FIG. 2.—PARSONS CONDENSING STEAM TURBINE.

The turbine used, a section of which is shown in Fig. 2, contains on its shaft seven revolving discs, each of which carries on one surface several concentric rings of brass blades, traveling in spaces between rings of fixed blades carried on annular discs fixed to the outer case. Thus each revolving disc with its next fixed disc forms a series of outward flow turbines, the steam entering inside the smallest ring and traveling up to the circumference, thence over and down to the centre of the next disc, and so on to the end. The discs, the blades, and the spaces between the blades are so arranged as to allow for full expansion of the steam in its passage from 115 lbs. pressure per square inch to an absolute pressure of 1 lb. per square inch.

TABLE III.

Trials with Alternate Current Armature and Water Resistance Superheating by the Gases from the Boiler Fire only.

Pressure by gauge on boiler, lbs. per sq. in.	Temperature of steam, ° Fah.	Load in electrical units per hour.	Feed-water per hour in lbs.	
			Total.	Per unit.
99	367	31.6	1180	37.3
97	394	49.9	1550	31.1
103	399	105.2	2970	28.2

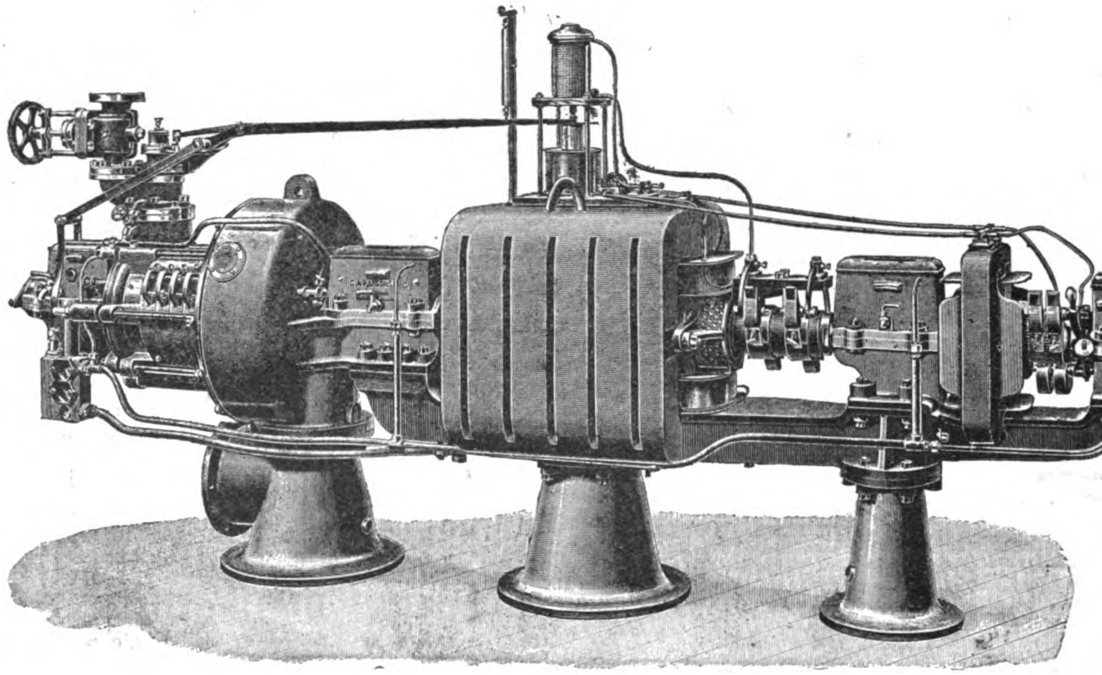

FIG. 1.—PARSONS CONDENSING STEAM TURBINE WITH DYNAMO.

The governor consists of a steam relay, in mechanical connection with the turbine shaft, which opens a double-beat lift valve, shown in Fig. 2, once in every 28 revolutions of the shaft. Thus the steam is admitted in periodic gusts. The duration of these gusts is controlled by a solenoid coil, connected as a shunt to the field magnets, and compound wound, so as to keep the volts constant. Attached to the core of this solenoid is a lever, the movement of which affects the action of the valve in such a way that at full load the admittance is almost continuous, whilst at light load it is quite intermittent.

The longitudinal pressure on the turbine shaft, due to the one-sided character of the six smaller turbine discs, is balanced at the high-pressure end by a revolving baffle piston with a number of deep grooves on its circumference, which are entered by corresponding projections on a fixed bush resembling a thrust-block. Any small amount of longitudinal thrust which may remain unbalanced is received by an adjustable grooved thrust bearing at the end of the spindle, beyond the main bearing.

The accompanying tables show three separate sets of trials made.

In the third set of trials the alternate current armature was used, giving 2,000 volts at a speed of 4,800 revolutions per minute, which made the frequency of alternations 80 periods per second.

The electrical energy was absorbed by a water resistance, the steam being moderately superheated as in the first set, up to about 400° Fahrenheit. The results are given in Table III. The close agreement of them with the corresponding continuous current trials, Table I, is important, as supplying evidence that in alternate current trials conducted in this manner the effects of lag in the external circuits are immaterial. The difference between the alternating and continuous current measurements is less than 1 per cent. of the output at full load.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED NOVEMBER 15, 1892.

Accumulators:—

Secondary Battery, R. Eickemeyer, Yonkers, N. Y., 486,091. Filed April 4, 1890.

Employs battery plates insulated from each other and arranged in a pile, the plates having corresponding openings through them which afford spaces for occupation by the fluid.

Alarms and Signals:—

Test Circuit for Burglar-Alarm Systems, E. R. Wilder, Kansas City, Mo., 486,149. Filed Aug. 22, 1891.

Police Signal System, J. C. Wilson, Boston, 486,206. Filed Oct. 14, 1887.

Electrical Annunciator, F. S. Carter, Burlington, N. J., and G. B. Stumpf, Philadelphia, 486,213. Filed Aug. 13, 1891.

Has for its object to reset the pointer by means of the current operating the annunciator at the time the return call is made.

Messenger-Call System for Buildings, F. H. Fuller, Springfield, and C. B. Perkins, Holyoke, Mass., 486,282. Filed April 5, 1892.

A system in which a single centrally located call box serves the purposes of a number of different individuals, by means of an inductor adapted to be set to designate any one of several rooms.

Electric Alarm, H. A. Hull, New Brunswick, N. J., 486,333. Filed April 30, 1892.

Invention consists of a rod having a contact point adapted to pass successively over the opposite faces of a contact spring, one of the faces being insulated.

Electro Magnetic Bell, J. J. Ross, Detroit Mich., 486,354. Filed December 29, 1891.

The armature is evenly poised between two or more electro-magnets so as to be unaffected by the inequalities of the magnets or the variations in the power of the battery.

Galvanic and Thermo-Electric Batteries:—

Electric Battery, J. J. O'Lalor, Boston, Mass., 486,264. Filed Oct. 3, 1891.

A battery in which the connections are automatically made by the act of placing the cover in position, and having a small motor or other device mounted upon the cover.

Distribution:—

Circuit Controller, H. W. Leland, Jersey City, N. J., 486,212. Filed Jan. 11, 1892.

Employs a disc provided with one or more elastic ridges and circuit controlling contacts embedded in the ridges.

Dynamos and Motors.

Electric Locomotive, W. E. Allington, E. Saginaw, Mich., 486,038. Filed June 9, 1891.

Provides means for varying the ratio of the speed of the motor to that of the driving-axle to facilitate starting.

Armature for Dynamo Electric Machines and Electric Motors, C. S. Bradley, New York, 486,078. Filed Nov. 17, 1890.

A drum-armature employing individual coils of windings placed in slots and held by their own mutual binding action.

Governing Electric Motors, R. Lundell, New York, 486,213. Filed Dec. 19, 1891.

Employs a motor whose armature and field magnet are each wound with independent sections of coils, and circuit changing devices for varying the series and relations of the coils.

Governing Electric Motors, R. Lundell, New York, 486,214. Filed Jan. 2, 1892.

Invention consists in providing a motor with several field magnet and armature coils, connecting the motor to a three wire supply system, and switching the coils in such a manner that the desired changes in speed shall be attained.

Armature for Dynamo Electric Machines, A. L. Parcelle, Boston, Mass., 486,234 Filed Nov. 7, 1891.

Employs an armature having apertures for containing the coils; each coil being composed of a number of independent insulated lengths of wire.

Regulator for Dynamo Electric Machines, A. Dow, Elgin, Ill., 486,417. Filed Mar. 20, 1891.

The combination of a pulsating current dynamo with a regulator adapted to vary the current in the field responsive directly to the varying range of pulsation of such current; the field magnets and regulator being independent of the main working circuit.

Lamps and Appurtenances:—

Regulable Electric Lamp, G. W. Hall and J. J. De Marr, Georgetown, Colo., 486,334. Filed Dec. 1, 1891.

Employs several filaments of different resistances.

Electric Arc Lamp, D. Higham, Boston, Mass., 486,377. Filed July, 9, 1892.

Employs a variable resistance in series with the carbons and a yielding connection between the feeding mechanism and the resistance, whereby the latter is acted upon to compensate for variations of the resistance at the arc.

Measurement :—

Electric Meter. J. Perry, London, Eng., 486,123. Filed June 5, 1892.

Employs a rotary circular body, means for sending a current from its edge to its centre, or vice versa, and means for producing Foucault currents in the body.

Miscellaneous:—

Wire Covering Machine, J. A. Barrett, Brooklyn, N. Y., 486,270. Filed May 2, 1892.

Sign for Electric Lamps, E. W. Clay, Louisville, Ky., 486,324, Filed July 21, 1892.

Apparatus for Recording Speech or Other Sounds, W. Bruening, E. Orange, N. J., 486,394. Filed July 28, 1891.

Workman's Time Register, C. J. Garnett and A. Moore, 486,399. Filed Oct. 20, 1891. Keighley, Eng.

Metal Working :—

Electric Forge, G. D. Burton, Boston, and E. E. Angell, Somerville, Mass., 486,176. Filed Jan. 12, 1892.

Employs an electrode readily manipulated, adjustable and interchangeable to suit differently shaped bars, and easily removable when worn out.

Railways and Appliances :—

Electric Railway Conduit, A. W. Wright, Chicago, Ill., 486,315. Filed May 13, 1892.

Has for its object to provide a solid subway structure in which the yokes resist the pressure of traffic directly upon the pillars thereof, and in which the slot-rails are supported against deflection.

Trolley for Electric Railways, A. H. R. Guiley, South Easton, Pa., 486,333. Filed Dec. 31, 1891.

A conduit for street railways having outwardly opening hinged covers.

Switches and Cut-Outs :—

Double Snap-Switch, R. Lundell, New York, N. Y., 486,215. Filed Feb. 10, 1892.

Electric Switch, E. P. Warner, Chicago, Ill., 486,241. Filed Feb. 16, 1891.

Employs a shield of insulating material placed in front of the metallic parts of the switch and containing a slot through which the handle projects.

Telegraphs:—

Telegraph System, A. Gipperich, Richmond, Va., 486,332. Filed July 30, 1892.

Has for its object to permit all main-line circuits leading to a central station to pass through the signal and switch mechanism, which is set in motion by some propelling mechanism and is adapted to open and close in rotation each main-line circuit to connect and disconnect it with a single call instrument.

Telephones and Apparatus :—

Microphone, C. Clamond, Paris, France, 486,244. Filed Mar. 21, 1892.

Employs a working resistance composed of elastic material adhering to both electrodes. (See page 519, this issue.)

LITERATURE.

The Standard Electrical Dictionary. By T. O'Conor Sloane, Ph. D. New York, 1892. Norman W. Henley & Co., vi + 624 pages. Cloth, 5 x 7 inches. Price, $3.

The lexicographer who at the present time undertakes the work of collecting and correlating the electrical nomenclature is met by a serious problem, owing to the fact that in many cases the meaning of terms is, and has been for some time, in a state of transition; and, again, he is confronted by the fact that in order to bring his work within the compass of a handy sized volume, such condensation is required as must of necessity make the definitions appear in many cases not sufficiently broad to the critical examiner. The interesting work before us shows the effect of these conflicting points in a marked degree, inasmuch as the author has attempted that most difficult undertaking, the making of a popular work on a scientific subject.

In glancing over the book we frequently encounter the obstacles above referred to, due to the transitory state of the science. Thus, in the definition of the word "anode," without necessarily going back to Faraday's definition which locates the anode as the limiting surface of the electrolyte in contact with the positive plate, the author defines it "as the positive terminal in a broken metallic or true conducting circuit;" also as "the terminal connected to the carbon plate of a galvanic battery, or its equivalent in case of any other generator. In general practice it is restricted to the positive terminal in a decomposition or electrolytic cell, such as the nickel anode in a nickel-plating bath, or the anode of platinum in a gas voltameter. It is the terminal out of, or from which, the current is supposed to flow through the decomposition cell."

It will be noted that the author has defined the anode more particularly with respect to its function in the plating cell, and has, to our minds, left out the broader view of the function and nature of the anode in general, as applied in the primary cell. It will also be noted that he applies the word "terminal" in a manner which, we believe, is not generally supported by current usage, and which might be apt to lead the novice astray.

Turning to the term "cathode," on the other hand, we find it defined as "the terminal of an electric circuit whence an electrolyzing current passes from a solution. It is the terminal connected to the zinc plate of a primary battery." Here it will be noted the author has again restricted the definition to the electroplating cell, but in this case the second phrase is still more misleading than in the case of the anode.

We must also take exception to the general definition of the term "characteristic curve," which the author states is a "curve indicating the variations in E. M. F. during the rotations of the armature of a dynamo or other generator of E. M. F." Although more specifically explained later on, this statement in itself would hardly convey to the reader the broad, fundamental idea of the characteristic curve.

The author defines a "Voltaic or Galvanic Couple," as "the combination of two electrodes, and a liquid or liquids, the electrodes being emerged therein, and being acted on differentially by the liquid or liquids." Without laying too much stress on the narrowness of the word liquid, considering the gelatinous electrolytes and other forms of modern "dry" batteries, we hardly think that the differential action of the liquid or liquids can be called the true source of E. M. F. It is certainly not the case in the zinc-carbon cells, such as the Bunsen, in which the function of one of the liquids, the depolarizer, is the oxidation of the hydrogen formed on the carbon electrode. There is no *differential* action in this case.

In defining the electromagnetic theory of light, the author has, we think, fallen into an error due to the transposition of terms, by stating that "with few exceptions dielectrics or non-conductors are transparent." If he had put it the other way round, so as to read, that most transparent bodies are non-conductors, the statement would be more correct, and in keeping with the theory propounded.

Under the head of "Rotating Field," the author gives as an example the Mordey alternator, in which "the armature, nearly cylindrical, surrounds the field, and the latter rotates within it, the arrangement being nearly the exact reverse of the ordinary one." This definition does not to our mind cover Mr. Mordey's alternator, as built for the last few years.

Under the head of "Ions," the author has given another example of the chaotic state in which the whole question of "positive" and "negative," as applied to the voltaic cell, is in. Thus, he says that the ion "which appears at the anode, or *negative* electrode, is the anion;" while a few lines below in the same paragraph he states that, "the anion means the ion, which goes to the anode, or *positive* electrode." Surely it is time that this everlasting tangle be finally unraveled, and it would not be out of place to bring the matter to the attention of the Electrical Congress to be held in Chicago next year.

We have here merely drawn attention to some of the more important points, which seem to us to require comment, but we cannot help drawing attention to the fact that the work has suffered considerably from bad proof-reading. We have also noticed a somewhat curious fact that in not a few instances the illustrations given are of English apparatus. We do not mention this in any spirit of chauvinistic envy, but merely to remark that the author might with advantage have illustrated American apparatus, preferably, in more than one case.

The dictionary gives evidence of a large amount of painstaking work on the part of the author, and possesses features which must be commended. Thus, among these, we have noticed that the author, wherever occasion required it, has furnished the synonyms of terms, and the book is given an additional value by an alphabetical index, which enables it to be consulted for terms both collectively and individually. As it stands to-day, the work will prove of value to the reader whether professional or non-professional; but we are convinced, and we do not hesitate to say, that with a thorough revision, which the second edition will without doubt receive, it can be brought to a high state of accuracy. The definitions are, as a rule, put tersely and concisely, so that the inquiring reader can carry away a defined, net impression as to what is meant; while any student who will spend his leisure hours over the volume will be amply repaid for his time and trouble. The book is very clearly printed in bold type on good paper, and is well bound.

SOCIETY AND CLUB NOTES.

MEETING OF THE NEW YORK ELECTRICAL SOCIETY.

THE next meeting of this society will take place in Prof. Chandler's lecture-room, Columbia College, Forty-ninth street and Madison avenue, on Thursday, Dec. 1, at 8 p. m.

Prof. Edwin J. Houston, of Philadelphia, will deliver a lecture on the "Magnetic Field," which will be illustrated by lantern projections and experiments.

The following is a synopsis of Prof. Houston's lecture:

Definition of field. Group of curious properties possessed by the magnetic field. Early knowledge of the world respecting magnetic phenomena. Various facts concerning the attractive and other forces of the lodestone. Magnetic effluvia—Boyle's early conception of the magnetic field. Experimental study of some of the more important properties possessed by magnets. Various magnets. Faraday's conception of lines of magnetic force. Various methods on the graphic representation of the magnetic field. General principles of magnetism deduced from a study of magnetic fields. General phenomena of magnetic induction. The part which induction plays in the production of magnetic figures. Magnetic permeability and susceptibility. Coercive force and magnetic retentivity. The magnetic and electrical flux. Paramagnetism, and diamagnetism. Methods of magnetization. Discovery of Oersted. Theories and hypotheses of magnetism. Fluid theories. Ampere's theory. Hughes's theory. Ewing's theory. Phenomena of the earth's magnetism. Causes of the earth's magnetism.

NATIONAL ELECTRIC LIGHT ASSOCIATION.

SECRETARY GEORGE F. PORTER announces that it has now been arranged to hold the sixteenth convention of the Association in the Bell Telephone Building, St. Louis, Mo., Feb. 28, March 1 and 2, 1893. Mr. Porter is now busy on preliminary work.

BROTHERHOOD OF ELECTRICAL WORKERS.

THE Brotherhood of Electrical Workers of America at Chicago have elected the following officers and adjourned: Henry Miller, grand State president, St. Louis, Mo.; P. F. Haley, first grand vice-president, Jersey City, N. J.; and J. I. Kelly, grand secretary-treasurer, St. Louis.

BROOKLYN INSTITUTE OF ARTS AND SCIENCES.

A LECTURE on "Arcs and Arc Lighting" by Mr. Robert S. Dobbie, illustrated by apparatus, lantern photographs and experimental demonstrations, will be delivered on Friday, evening, Dec. 2, at 8 o'clock.

LETTERS TO THE EDITOR.

THE SPRAGUE-PRATT ELEVATOR.

WITH reference to Mr. William Rosenbaum's comments in your issue of November 16th, it is evident that the gentleman has had a very limited experience with electric motors, and especially as applied to elevator service. It would be well to remind him that with any well constructed machine, free from internal friction, where the duty required of the motor is measured by the work at the hoisting ropes, the motor cannot be stalled by any load which will be in practice put upon it.

It seems possible that Mr. Rosenbaum is the spokesman of someone else, and the purport of his comments would be more clear if he had so announced himself.

FRANK J. SPRAGUE.

NEW YORK, Nov. 26th, 1892.

LONG ELECTRIC ROADS.

IN the issue of November 9, of the ENGINEER, it was stated that the electric road between Baltimore and Washington was the largest project of the kind on foot at present. I understand that there is an electric road planned between Chicago and St. Louis, and work has already commenced on it in Illinois, which is expected to be finished in season for the benefit of World's Fair visitors. It is also claimed that a speed of 100 miles an hour will be attained.

I would like to ask if this is not something ahead of the Washington-Baltimore road?

J. WILSON BROWN.

BRIMFIELD, MASS., Nov. 22, 1892.

(Our statement was correct as far as it went. The difference between the two roads is that one is meant for through travel at a high rate of speed, and that the other is to be practically a street railway, running along a boulevard, and dropping passengers wherever they wish. Each is, therefore, we think, "the largest project of its kind."—EDS. E. E.)

PERSONAL.

MR. L. H. HART, who during the past year has had charge of the business of the W. J. Johnston Company, Ltd., has resigned his position and will hereafter have no connection with that concern. Associated with two or three other gentlemen well-known in trade journalism, he has bought out an old steam fitting paper in Boston, and will now publish it under the new auspices in this city, with the name *Heating and Ventilation.* It will be a handsome, well-edited monthly, and the first number issues early in January, with Frank W. Foster, president; H. M. Swetland, general manager and treasurer, and L. H. Hart, vice-president and secretary. Last week, Mr. Hart was given a luncheon by the staff of his old office, and was made the recipient of a beautiful little testimonial in the shape of a gold Odd Fellows' watch charm. Mr. Hart will now have a favorable opportunity to display his many excellent qualities, and in his new career he will start out with the hearty good wishes of a host of sympathizers and friends in the electrical field.

MR. EDWARD C. BOYNTON, M. E., recently of the Thomson-Houston Company, has been appointed electrician of the Lovell Manufacturing Company, Ltd., of Erie, Pa.

LEGAL NOTES.

TELEGRAM DELIVERY ON SUNDAY.

IN Georgia the telegraph companies will hereafter be exempt from penalties for failure to deliver messages on Sunday. The Supreme Court has decided that by Section 4579 of the Code it is made unlawful for any person (and this includes a telegraph company) to pursue his business or the work of his ordinary calling upon the Lord's day, works of necessity or charity only excepted. It follows that a telegraph company is not put by law, and cannot put itself by contract, under any duty to transmit and deliver messages on that day unless by reason of the subject matter of the messages in question that transmission and delivery can be fairly considered as a work of necessity or charity. A message from a son to his mother informing her that a particular person, a friend of the family, will arrive on a particular train, the object to apprise her that he, in company with the son, would be with her to take dinner, is not a message which can give to the work of transmitting and delivering it the character of either necessity or charity. A failure to perform the work on the Lord's day with reasonable dispatch will not subject the company to the statutory penalty, and an action therefor is not maintainable.

PATENT NOTES.

THE CANADIAN PATENT LAW.

SINCE the passage of the new Canadian patent act applications for patents have been rapidly increasing. Before the new act, inventors in this country were obliged to postpone applying for patents in Canada, until the United States patent was actually issued; otherwise the term of the latter would be but 15, instead of 17, years. Now, however, the inventor may file his applications in the United States and Canada at the same time, as the term in Canada has been changed from 15 years to 18 years. No models are required by the new act, except (as in the United States) that the Commissioner has the right to call for a model in particular cases.

All caveats expire upon issue of the United States patent for the same invention. For a period of one year after the grant, a United States inventor may import the patented article, to learn if his invention takes in Canada and to make arrangements to manufacture there.

FIRE UNDERWRITERS AND CENTRAL STATIONS.

A PAPER containing some 25 questions covering all the essential points in regard to the financial and material excellence of central stations, has been issued by Mr. George P. Low, electrical inspector of the Pacific Insurance Union, to every electric railway and lighting station within his jurisdiction, for the purpose of gathering authentic statistics and showing the falsity of the belief, still held by many underwriters, that a central station is an undesirable risk.

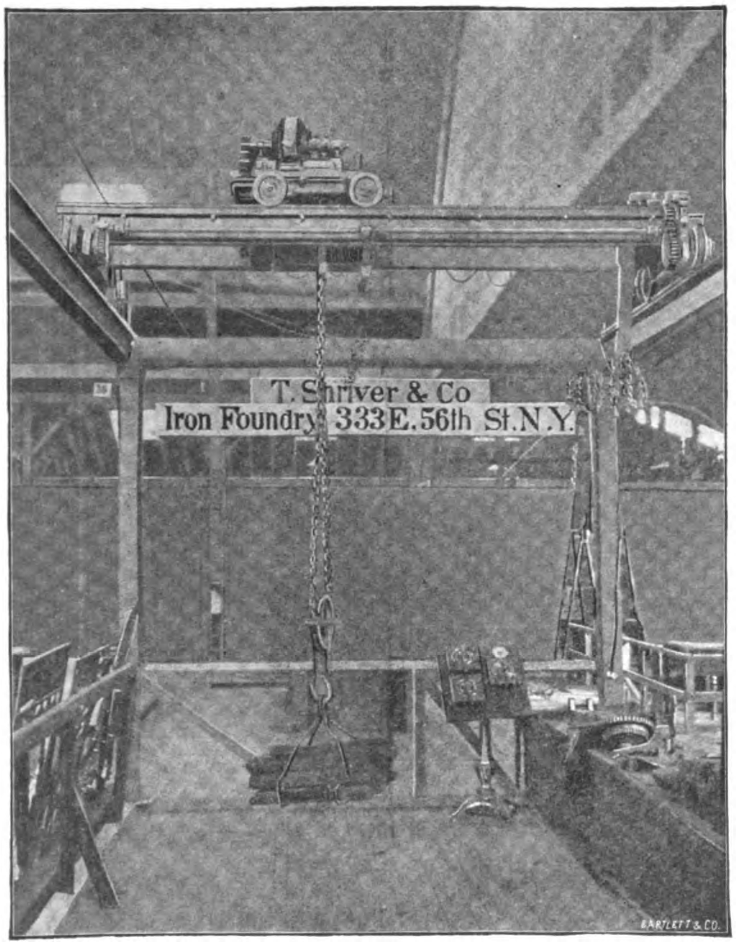
TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

Let your goods be known among all men.

T. SHRIVER & CO.'S NEW ELECTRIC CRANE.

In presenting to our readers this illustration and description of the Shriver crane, we shall deal with only one of the two classes of hoisting machinery. This is a device that not only raises or lowers its load, but shifts it as well horizontally at will. Friction is no doubt one of the greatest obstacles encountered in any load lifting device. No machine can be constructed to fully attain perfection, but there is no reason why it cannot be nearly accomplished. There are, however, a great many machines manufactured that do not nearly approach it, the cause being the undue friction of various parts. The contacts in the worm and worm wheel systems are sliding ones, and under the best possible condition, it is said, show a necessarily great loss by friction. In the crane here illustrated differential gears are used exclusively, thus avoiding much of the friction which, it is claimed, has hitherto counteracted their usefulness. In the manufacturing of the Shriver crane, together with the above good points, it may be said that the bridge carrying this crane is constructed of the very best steel beams, strongly framed. It is so constructed as to travel freely and square on the tracks on which it moves, no matter at what point on the bridge the load may be. In the construction of the Shriver crane, the motors of the C. & C. Electric Motor Co. are used. There are three motors for the equipment of each crane—that is, one motor for each movement—viz., 1st. The raising or lowering of the load; 2d. The movement of the motor carriage or crane upon the beams; and 3d. The moving of the entire device backward and forward on its elevated tracks. Each of the three motors or movements has its own controlling switch and reversing box. These can be operated singly or all at the same time.



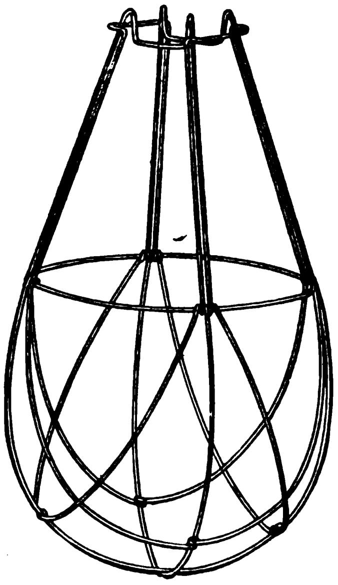
New Shriver Electric Crane.

This crane is made and sold by T. Shriver & Co., 333 East Fifty-sixth street, this city. The Shriver electric crane, as shown in the illustration, is on exhibition at the American Institute Fair, this city, where it may be seen in operation every afternoon and evening. This particular machine has been fitted with the motor wiring and controlling device of H. Ward Leonard & Co., 136 Liberty street, this city. The advantages to be derived from the use of this system are self-evident, when it is understood that by this system the operator has much more perfect control of the crane, besides the fact that there is an economy in power consumed, as only the exact amount of current required is generated, avoiding the use of large and expensive resistance boxes, which are, of course, a destructible and expensive part of an electrical outfit.

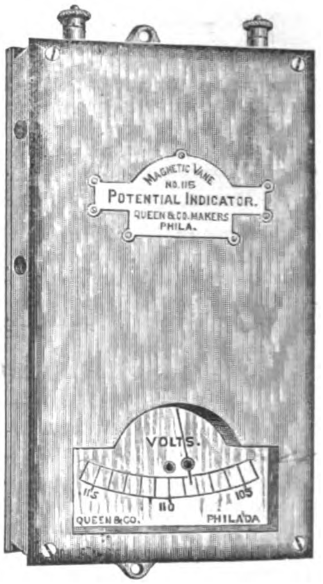
QUEEN'S POTENTIAL INDICATOR.

We illustrate herewith a new potential indicator which Queen & Co., of Philadelphia, are placing on the market. It is built upon the general plan of their "Magnetic Vane Voltmeter," and is mounted in a handsome mahogany case with open scale divisions, so that very close readings can be made. No permanent magnets or other parts which change with age are used in construction, so that constancy is assured. This is a very essential feature, as most instruments require frequent calibration—an item of considerable expense as well as annoyance. The indicators as kept in stock are adjusted for 110-volt circuits, but special ranges will be made to order. They are adopted for isolated plants and central stations. Queen & Co. are just issuing circular No. 395 which contains prices and full particulars.

Queen & Co. are now putting on the market the new ballistic galvanometer, concerning which an excellent article by Mr. E. G. Willyoung appeared in the Engineer of Nov. 16. They have issued a neat circular, No. 400, on the subject, implying that this completes their "four hundred" of elite instruments—subject, of course, to a revision of the rôle of honor from time to time.



Acme Expanding Wire Guard.



Queen's Potential Indicator.

THE ACME EXPANDING WIRE GUARD.

The "Acme Expanding Wire Guard" is the latest device on the market for the protection of incandescent lamps. It differs from others on the market in the fact that it requires no auxiliary clips or catches, but secures itself firmly on the socket in a way that is almost automatic. It has a very firm hold on the socket, having a bearing contact longitudinally on the shell of over half an inch, making it almost impossible to force it against the lamp with a blow. The guard itself is also made particularly strong and rigid. In appearance it is also a decided improvement, and is really handsomely symmetrical. The Acme guard is being placed on the market by the Electric Appliance Company, who are the manufacturers and sole agents. It is already having a large sale.

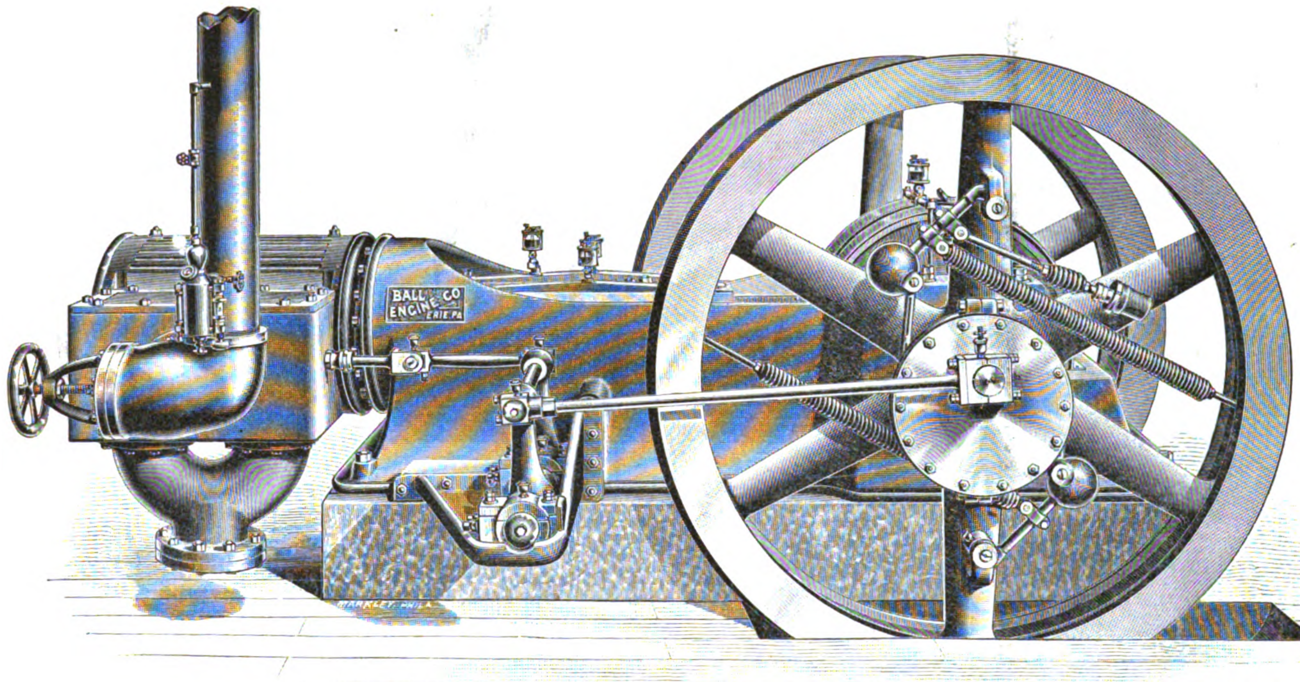
The Valentine Clark Company, dealers in poles and ties, have removed from their offices on the fifth floor of the Rookery Building to larger and more sumptuous quarters in suite 704–706, the Rookery. They needed more room to take care of their growing business properly.

NEW HEAVY DUTY BALL ELECTRIC RAILWAY ENGINE.

In selecting an engine for electric railway service, the character of its duties should be carefully considered. It will be found that the work is very exacting and severe, and the engine should be adapted for heavy duty, varying load, and long, continuous runs. It should, therefore, have great weight and strength, with sufficient metal so distributed as to receive the various strains and thrusts of moving parts without deflection or vibration. The engine shown in the illustration was designed by the Ball Engine Company, Erie, Pa., especially for electric railways and electric welding, and possesses the above requirements to an admirable degree, as may be seen from the cut, and the description following.

The frame of the engine is massive and heavy and internally ribbed so as to give the greatest attainable stiffness. The crank shaft is forged out of a solid steel ingot of the best quality, and is of large diameter and great strength. The connecting rod and straps are forged out of steel ingots and are of a new design, combining strength with efficiency. The main bearings are unusually large, and are so arranged that both the vertical and side wear of the liners may be taken up. The main bearing liners are genuine babbitt, carefully scraped and fitted, and as they are made removable, they can be quickly and easily taken out and replaced with new ones if necessary. The crank pin boxes are lined with genuine babbitt. The crosshead boxes are made of pure copper and tin. The crosshead is a steel casting with very large bearing surfaces and is babbitted on the four faces with genuine babbitt. The crosshead pin is tool steel, and the piston rod a fine quality of crucible steel. The oiling devices are of the most improved form, and all fittings are complete and of the best description. The regulation by means of the improved governor is such that the engine has shown in practice perfect regulation under conditions where the variation in load on the generator from zero to the full capacity has occurred in less than five seconds.

Without going into any further details, it will suffice to say that thorough workmanship and materials of the highest excellence go into the construction of the engine, and every detail receives the most careful attention. The manufacturers, the Ball Engine Company, Erie, Pa., believing that the electric street railway interests require a strictly first-class engine in every respect, have designed the engine to that end, and have, they think, succeeded.



BALL ENGINE CO ERIE PA

NEW HEAVY DUTY BALL ELECTRIC RAILWAY ENGINE.

The Kester Electric Company, of Terre Haute, Ind., report the following sales of direct current apparatus since November 12: Standard Wheel Company, Fort Wayne, Ind., 300-light dynamo; Louis Snider's Sons Co., Hamilton, Ohio, 200-light dynamo; John Ruby, Louisville, Ky., 7½ h. p. motor; Blair & Failey, Terre Haute, 50-light dynamo.

LARGE SALES OF KESTER DYNAMOS AND MOTORS.

The Kester Electric Company, of Terre Haute, Ind., report the following sales at the end of October: 30-light dynamo, Zimmerman & Stahl, Terre Haute, Ind.; 50-light dynamo, Jones & Hill Co., Elkhart, Ind.; 50-light dynamo, Kelley Bros., Goshen, Ind.; 50-light dynamo, D. W. Williamson & Co., Indianapolis, Ind.: 3 h. p. motor, Moore & Langen, Terre Haute, Ind.; 2 h. p. motor, Cooper Manufacturing Co., Saint Joseph, Mich.: 2 h. p. motor, Lincoln Electric Railway Co., Lincoln, Ill.; 5 h. p. motor, Heat, Light and Power Co., Muncie, Ind,; 1 h. p. motor, Van Nort Bros., St. Louis, Mo.; 7½ h. p. motor, Decatur Gas, Light and Coke Co., Decatur, Ill.; 10 h. p. motor, A. H. Crawley & Co., Peoria, Ill.

THE F. P. LITTLE ELECTRICAL CONSTRUCTION AND SUPPLY COMPANY.

A new concern with the above title has just been incorporated at Buffalo under the law of the State of New York. The directors are S. F. Eagan, Peter P. Miller, F. P. Little, John L. Williams and C. R. Huntley, and at the election of officers the following were chosen: John L. Williams, president; Peter P. Miller, treasurer, and F. P. Little, secretary. The capital stock is $100,000 with a provision in the incorporation papers for increasing to $250,000 whenever desired. One-half the capital is already paid in, and the incorporation is complete in every detail. The old firm of F. P. Little & Co. will go out of business on January 1, having made a very clean and brilliant record in the field of electrical construction. The new company, whose incorporation is due to the success of the old firm, will have even larger opportunities of usefulness and profit, and under Mr. Little's skillful guidance may be depended upon to make the most of them.

LA ROCHE ELECTRIC WORKS.

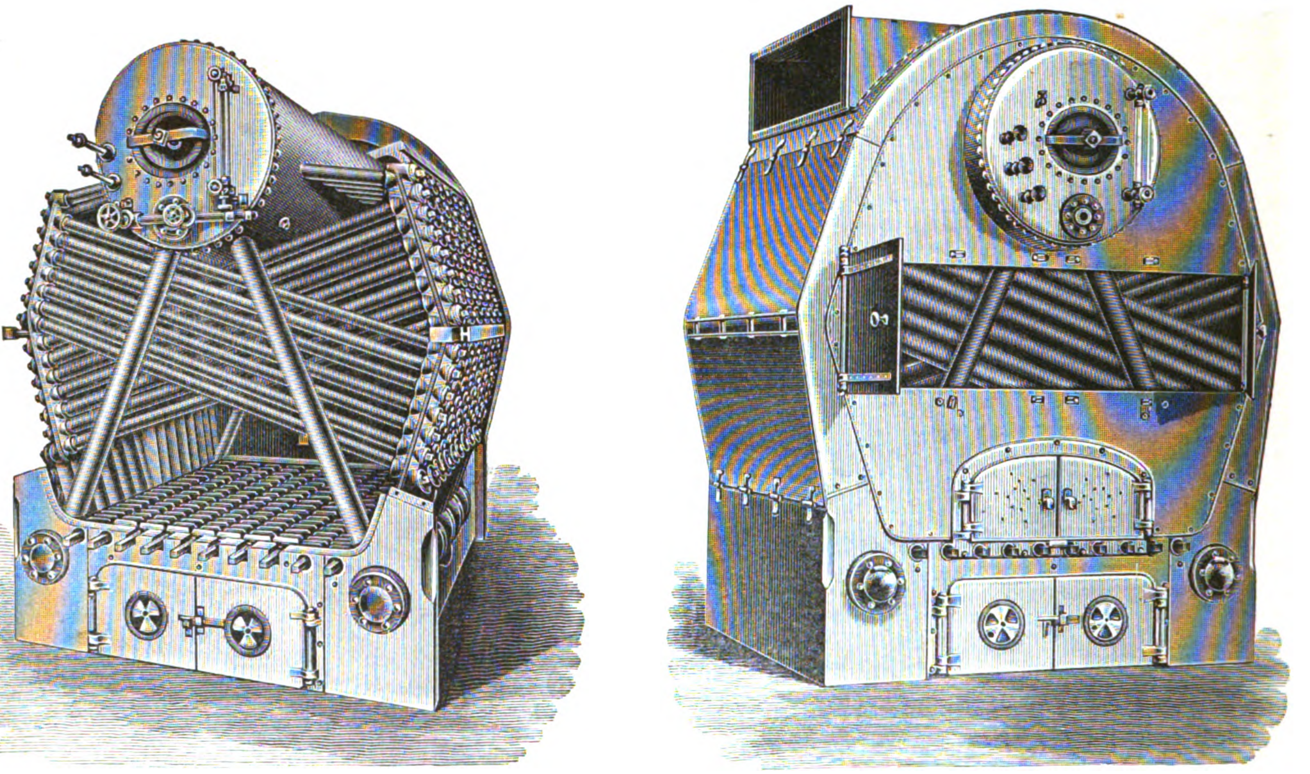
The above works of 116–118 North Sixth street, Philadelphia, write us to correct a statement made in a contemporary as to the wiring of the Winter Circus. They state that it is they who are doing the wiring at the new place of amusement, and that they are putting in the entire installation, which promises to be, as usual, a fine piece of work. The mistatement probably arose from the fact that the La Roche Works employed another concern to wire up for a few extra lamps, which the Works were too busy to put in themselves at the moment.

Mr. Avery P. Eckert, who has become widely known in connection with Kerite, has transferred his field of usefulness to the South. He has just returned from an extended trip, in which he visited all the Southern States and secured a number of good orders for the famous Kerite wires and Kerite elastic tape.

THE NEW YORK SAFETY SECTIONAL WATER TUBE BOILER.

The accompanying illustrations show a sectional boiler manufactured by the New York Safety Steam Power Co. of 30 Cortlandt street, this city, designed to be economical of valuable space, and at the same time to be of liberal proportions in grate area and heating surface. The interior is readily accessible from the outside, for examination, cleaning or repair. The furnace extends under the entire boiler, and is of proper height to permit the use of any kind of fuel. As will be seen upon reference to Fig. 1, the tubes are arranged in transversely-inclined series of several tubes per section, and are all straight. Each tube is lap welded, and expanded at the ends, and is wholly in the furnace directly over the fire. The proportion and combination of parts throughout the boiler is such that expansion and contraction, due to changing temperatures, can occur without straining, and, the tubes being short, tubular expansion is greatly reduced.

These boilers are proportioned and rated for generating power on the basis of the Centennial standard—namely: "The evaporation of 30 pounds of water, at 70 lbs. pressure, from temperature of 100° to be 1 h. p. Said duty to be accomplished with a consumption of anthracite coal of good quality, at rate of twelve pounds per hour per square foot of grate with good natural draft."



Figs. 1 and 2.—New York Safety Sectional Water Tube Boiler.

The actual steaming efficiency, and also the ultimate capacity, is largely in excess of this rating. In this boiler, each section of tubes and headers is tested under 500 lbs. hydrostatic pressure. The main steam drum is made of open-hearth homogeneous flange steel plate, having a tensile strength of not less than 60,000 lbs. per square inch of sectional area, and possessing sufficient homogeneousness, toughness and ductility, to show a contraction of area not less than fifty per cent. while the plate employed is of proper thickness to enable the boiler (under government standard of pressure allowable) to carry a working pressure of 250 pounds per square inch. The water circulation is natural and positive. It is passed through the tubes and exposed to the action of the fire in a steady and continuous flow. The steam generated is quickly conducted to the drum, and in consequence of the ample disengaging surface provided, separates from the water without turbulence, and becomes dry steam ready for use.

The system of cross-tubes employed in this boiler results in the concentration of heating surface to a remarkable degree, yet it does not contract the area of grate. Hence the capacity of the boiler in horse power per cubic foot of space occupied is very great. By reason of its sectional character, this boiler can be delivered in places wholly inaccessible to many other desirable boilers. A boiler of 200 h. p. can be passed through a 4 feet by 4 feet doorway, window, or sidewalk opening. A boiler of 100 h. p. occupies a floor space 7½ feet square, and is less than 10 feet high.

Fig. 2 shows the boiler with the casing doors open affording access to the tubes.

KEYSTONE ELECTRIC WORKS.

As an evidence that advertising in The Electrical Engineer pays, the Keystone Electric Works, of Erie, Pa., as a result of their advertising, have recently shipped to Valparaiso, one of their 40-light dynamos—the order having come through Messrs. Hickox & Reed, of Chicago. Verily, The Electrical Engineer "thoroughly covers the electrical field."

ELECTRICAL SUPPLY COMPANY.

The motor department of the Electrical Supply Company, Chicago, which was recently added, has each month shown an increase in the amount of business done and so important has that department become, that Mr. F. S. Terry, manager of the Supply Company recently visited the factory of the Crocker-Wheeler Company, whose motors are handled exclusively, with a view of learning something in reference to their manufacture, and he was greatly interested in the care taken in every part. Mr. Terry feels confident that with motors of such superior quality, this department of the Supply Company's business will continue to increase until in a year or two, it may be the most important branch of their trade.

At the Cleveland meeting of the American Street Railway Association, a little brochure, issued by the Electrical Supply Co. was circulated among the members. It consists of about 30 leaves of heavy plate paper tied together, each bearing a beautifully executed engraving of some piece of street railway apparatus. A cleverly worded dedication to the association, and a list of its first officers elected in 1882 complete a very tasteful souveinr.

AUBURN ELECTRIC MOTOR COMPANY.

The Auburn Electric Motor Company, of Auburn, Me., is a new concern, which appears to be meeting with much success in building dynamos and motors. It has not been able to keep up with its orders, and expects to be obliged to enlarge its facilities very soon. It has just put in a 100-light dynamo in the Fitz Brothers' Last Company's new shop, and the plant is working finely. It is also building a 100-lighter for the Jordan & Frost planing mill at Lewiston. These dynamos are the design of Mr. W. F. Brown, the electrician of the company.

THOMPSON & PINOLET.

Messrs. Edward P. Thompson of this city, and Louis M. Pinolet, of Montreal, have entered into a copartnership under the firm name of Thompson & Pinolet, patent solicitors, with offices at 5 Beekman street, New York city and 1401 Dorchester street, Montreal, Canada. They report a great increase of Canadian business since the passage of the new patent act.

WESTERN NOTES.

THE CHICAGO EDISON COMPANY will erect immediately a large plant to furnish light and power on the North side, and the work has already been begun. The new power house is to be located on the Newbury Library grounds in the rear of the Library Building on Oak St., between Dearborn avenue and Clark St. This power house will be of large dimensions, giving room for growth, and starting off with about 1,000 h. p. capacity. Numerous requests have been received by the Edison Company from residence owners in that section of the city for current. The machinery, boilers, engines, motors and underground conductors have been ordered, and work of wiring residences and stores will commence at once, and the whole plant will be completed and running about May 1st. The improvements are to cost half a million and the lights are to be extended as rapidly as demanded. The area to be supplied at once will extend from the north limit of Lincoln Park to Ohio street on the south and from Wells street to the lake. The large plant now being built at Harrison street and the river is being pushed along rapidly. When this plant is finished, the north side power house will be used as a substation, drawing on the main station for an extra supply when required. Next year the west side will be equipped with the system. The station at Harrison street and the river is to be a capacity of 35,000 h. p. Some exceedingly large feeders have been laid, connecting the present Edison station on Adams street with the new one in process of construction on Harrison street; the positive and negative feeders are of 1,800,000 c. m. capacity and the neutral of 900,000. Special arrangements have also been made by means of switches to use a portion of the neutral copper on the outside conductors if required, and also for cutting in and out the sections of the feeders according to the load.

THE CENTRAL ELECTRIC COMPANY report the heaviest sales for Okonite wire in the month of October that they have ever experienced. The demand for high class goods seems to be daily increasing, as consumers are waking up to the fact that permanency is the essential point in electrical construction. The Washington carbons are finding a ready sale, several of the largest companies throughout the country having contracted with the Central Electric Company for all the carbons they use. They report having several handsome orders for large construction jobs, and feel convinced that the next two months will be very busy ones.

THE LINDELL ELECTRIC LINE, at St. Louis, suffered last week a heavy loss by fire, which broke out in the car house. The burned structure is a large building of brick and stone in the shape of an oblong. An attempt was made to roll some of the motors out in the street away from the fire, but their great weight prevented these efforts from being successful. It was found impossible to save the building or its contents on account of the fierceness of the fire, but it was prevented from reaching other buildings. The loss, estimated at $150,000, was fully covered by insurance.

THE KNAPP ELECTRICAL WORKS have recently closed a very large contract for Safety wire in Cleveland, Ohio. This brand of wire is receiving well-merited attention, and the trade in it is increasing. The Knapp Electrical Works of Chicago have been appointed exclusive general western distributing agents for the Ries regulating sockets for the States of Illinois, Indiana, Ohio, Michigan, Iowa, Wisconsin, Minnesota, Missouri and Colorado. The Ries socket enables the consumer to burn his lamps at any desired degree of brilliancy.

THE CROWLEY ELECTRIC CO. has been organized with offices and headquarters at 18 West Superior street, Duluth, Minn. The new company will deal in all kinds of electrical supplies, do all kinds of electrical work and handle an extensive and comprehensive line of combination and electric fixtures. The gentlemen connected with it are well-known in the electrical circles of the Northwest and have installed a large amount of electrical work. They guarantee to treat everyone right who has any dealings with them.

THE POCKET TELEPHONE DIRECTORY of Chicago's electrical people and engineers, etc., issued by Mr. Chas. E. Gregory, the dynamo and motor dealer of that city, has received the hearty appreciation of all those who have been fortunate enough to receive one. It is in the form of a small note book for the vest pocket with ample blank sheets for voluminous note taking. The idea is somewhat of a novel one and highly creditable to Mr. Gregory's genius in little matters of this kind.

THE ELECTRICAL SUPPLY COMPANY have issued two engravings representing the interior of a street car "before and after using" the Carpenter heaters. These heaters are being actively pushed, now that cold weather has come, and the company anticipate large sales.

MR. THOS. G. GRIER, agent for the Bryant Electric Company, whose offices are in the Monadnock Building, Chicago, is enjoying a constant and steady demand for their switches and sockets.

MR. H. L. PARKER, the president of the Emerson Electric Manufacturing Company, of St. Louis, Mo., manufacturers of electric lighting and railway specialties and alternating current motors, spent several days in Chicago recently. Mr. Parker states that he has still got his elephant on his hands, but he didn't bring him to town with him, as all the readers of the ENGINEER are familiar with him from seeing his portraint therein, and they are not anxious to "see the elephant."

THE ELECTRIC APPLIANCE COMPANY have been engaged for the past few weeks in rearranging and enlarging their store and office to make room for the larger working force necessary to take care of their rapidly increasing business. The demand for their numerous specialties is rapidly on the increase. The call for their new Acme wire guards has been so heavy that the factory has been swamped with orders, and they are making arrangements to largely increase their facilities.

MR. GEO. CUTTER, 329 Rookery Building, Chicago, is, as usual, hard at work filling orders for his famous specialties. He always seems to have just the little articles that the central station man needs. He has always made a particular study of designing and handling the choicest kinds of specialties, and his name has become a household word from his ingenious method of advertising and the quality of his goods among the stations all over the country.

MR. WILLIAM PATTON, inventor of the Patton motor system, has just returned from Louisville, where he has been starting up the first consignment of cars built for that city. The car in operation there does its work very successfully, and everyone, from the officials of the road down, were delighted with it. The street railway connecting Pullman with the Chicago street railway and the World's Fair will be equipped with this system.

MR. A. H. ENGLUND, secretary and treasurer of the International Register Company, 300-302 Dearborn street, Chicago, is much pleased with the way orders are coming in for the fare register for street railways manufactured by them. It meets with general satisfaction from users, and their repeat orders are numerous. It is exceedingly neat and compact, and the workmanship throughout is of the best.

THE MASSACHUSETTS ELECTRICAL ENGINEERING COMPANY, through Mr. Phillip Harvey, manager of their Chicago office, room 201, First National Bank Building, are just preparing complete plans and specifications for the entire lighting of Oconto, Wis., and the vicinity. Any inquiries from firms desiring to bid on electrical machinery should be addressed to Mr. Harvey in Chicago.

MR. M. B. AUSTIN, who was for some six years associated with the Western Electric Company, and who allied himself with the Knapp Electrical Works last October, is securing a large amount of business for his company, and looks hale and hearty in the midst of prosperity. Mr. Austin is a pushing, energetic salesman and never fails to capture a nice order when it is in the field.

THE ENTERPRISE ELECTRIC COMPANY, 313 to 315 Dearborn street, Chicago, report the recent shipment to them from the National India Rubber Company's factory at Bristol, R. I., of two car loads of all sizes of their wire and cables, to fill orders and make an attempt at stocking up. The demand for these excellent wires was never larger.

MR. COOKE, the Chicago agent of the Buckeye Electric Company, reports a flourishing demand for Buckeye lamps. They have recently brought out a new double-looped filament lamp, which gives a very beautiful diffusion of the light and is exceedingly attractive.

THE PIONEER ARMATURE WORKS are receiving numerous consignments of burned-out armatures to undergo their healing treatment. They make a specialty of this work and guarantee all rewinding to be first-class in every respect.

MR. J. F. MACARTNEY, traveling salesman of the Railway Equipment Co., Pullman Building, Chicago, has returned from an extended trip and is spending a day or two here.

MR. F. S. TERRY, manager of the Electrical Supply Company, of Chicago, has gone East to eat Thanksgiving dinner in his paternal halls, and will be absent for about a week.

G. E. HORN & CO., 63 South Canal street, are receiving a great many orders for their bells, for which they make many strong claims, among others, durability and cheapness.

THE ILLINOIS ELECTRIC LAMP CO. say that business is very good with them and Jewel lamps which they manufacture are giving very general satisfaction.

W. C. LYMAN, 49 Michigan street, reports business as very lively in exhaust heads and orders are coming in briskly all the while.

THE POND ENGINEERING CO.

The Pond Engineering Co., of St. Louis, Chicago and Kansas City, announce that they are prepared to furnish any style of pump valve adapted to the standard makes of pumps, and to withstand the action of any liquid. They make a specialty of hard and soft rubber valves, usudurian valves, Jenkin's valves, naphtha valves, comb rubber valves, metallic valves, etc., and carry a very large stock. Among their other specialties may be mentioned the Hoppes live steam feed water purifier, for preventing scale, made in sizes from 50 to 1000 h. p., the Blake steam pumps, and the Sheffield grate bar, which is claimed to give 50 per cent. air space and to be proof against burning or warping. The standard slide valve engines and the boilers manufactured and sold by this company are too well known to require description.

A neat little 16-page pamphlet, entitled "How to Obtain Dry Steam," is the Pond Engineering Co.'s latest addition to the literature of mechanics, and contains engravings and subject matter relating to the Pond separator, together with a partial list of users containing the names of 36 well-known companies, institutions and individuals.

THE NEW ENGLAND ENGINEERING COMPANY.

Mr A. M. Young, of Waterbury, Conn., and his friends, have purchased the New Britain Electric Light Company and the New Britain Tramway Company, and intend to build a new and modern power station for the supply of electricity for light and power. They have already begun the work of relaying the track, and will equip the road electrically within the next two months. They propose to make it a first-class plant, embodying all the latest advances in the art.

Mr. Young and associated capitalists have also bought the Palmer and Monson Electric Light Companies, and have purchased a very large water-power lying between the two towns, at Blanchardville. They will put in a combination water and steam plant to light both Palmer and Monson and to supply power to the heavy manufacturing concerns that are situated in that region. Another purchase is that of the Rockville Gas and Electric Company. A similar increase of capacity will be made, for gas and electricity alike, and it is proposed to secure, if possible, legislation which will enable the building of several miles of electric railway.

NEW FACTORY FOR THE CARD ELECTRIC MOTOR AND DYNAMO CO.

Owing to the rapid extension of their business, the Card Electric Motor & Dynamo Company, of Cincinnati, have secured possession of one of the most eligible factory sites in that city. It is the southeast corner of Hunt street and Broadway, where they propose to erect at once a large new factory for themselves. The building is to have a frontage of 175 feet on Hunt street and a depth of 86 feet. The whole of this space will be covered with a three-story building, the plans of which are now receiving the architect's finishing touches. It is hoped to begin the building in December, to push the work to the utmost, and, with favorable weather, to enjoy occupancy of the new quarters not later than the first of February.

NEW YORK NOTES.

Mr. Frederick Saxelby, until recently in the selling department of The General Electric Co., with headquarters at Philadelphia, has resigned and accepted a similar position on the staff of Mr. Charles D. Shane, No. 136 Liberty street, New York. In his new capacity Mr. Saxelby will handle the Weston instruments, the Carpenter enamel rheostats, the Sunbeam incandescent lamps, and the manufactures in general of the Siemens & Halske Electric Co. The large experience which Mr. Saxelby has gained during his ten years' active work in the Edison lamp works will make him a welcome visitor in many electric light stations, and we have no doubt that Mr. Saxelby's many central station friends will, as heretofore, welcome him in his new capacity.

Wright Universal Electric Company.—At a recent meeting of the officers and directors of the Wright Universal Electric Company Dr. Robert Taylor was appointed a director and was as well made secretary of the company. The Doctor has been very successful in introducing the many specialties of this company, and some very nice orders have been booked at the American Institute Fair, where a splendid exhibit of bicycle lamps, postmen's and conductor's lamps is shown. Dr. Taylor devotes a considerable time each day at the fair interesting the many visitors to the exhibit.

W. R. Brixey, manufacturer of the famous Kerite insulated wires and cables, is adding to his already large factory two large additions. One 120 x 48 feet and one 60 x 45 feet. Also is putting in a new Abendroth & Root water tube boiler of 155 h. p., a Green horizontal engine of 125 h. p., and has just had erected a 400 Edison electric light plant.

Mr. J. E. Ham, has been appointed general agent of Day's kerite, at the New York offices, 203 Broadway, where he will have full charge of Mr. Brixey's interests. Mr. Ham is entitled to warm congratulations upon his promotion, which he has won by years of faithful and intelligent work in looking after the books and correspondence of the concern at this end of the line. Mr. Brixey will continue to alternate between New York and the factory at Seymour, Conn.

The Brush Electric Company have just completed the installation of a 30 arc light plant at the factory of Benedict & Burnham, Waterbury, Conn., and a 60,000 watt Brush alternating plant at Cornwall-on-Hudson, N. Y., both of which plants were recently sold by Mr. A. D. Dorman, of the New York office of the Brush Company.

The Short Electric Railway Co. have removed from their offices in the Mills Building, and are now gathered under the wing of "the old lady of Broad street," their present offices now being established at No. 44, where the General Electric Company broods, with a sub-company beneath each feather.

Mr. James B. McCreary, Brown's Building, Buffalo, N. Y., has taken the representation of the National Electric Manufacturing Company in New York State west of Syracuse.

NEW ENGLAND NOTES.

The Lobdell Car Wheel Co., of Wilmington, Del., have placed the contract for their new machine shop with the Berlin Iron Bridge Co., of East Berlin, Conn. The building will be 67 feet in width, divided into a central portion, 25 feet in width, with a wing on each side 21 feet in width. The central portion is controlled by a 15-ton traveling crane. The building will be 151 feet long, the entire framework being of iron, the side walls being of brick.

The Whitney Instrument has already won its way into favor, and the Electric Appliance Company are receiving daily orders from customers who have given the instrument a careful test and are well pleased with its operation. Their new Acme expanding wire guard is also meeting with a large sale and will undoubtedly be generally used in the course of only a short time.

The Massachusetts Chemical Company, No. 8 Oliver street, Boston, C. A. Baldwin, president, report that their sales of Insullac are increasing very rapidly, and that they are selling to the largest electrical companies in the country. They are vigorously urging its claims as the best insulating compound yet discovered.

PHILADELPHIA NOTES.

Harry S. Smith & Co., Ltd., are having their store stocked with one of the finest lines of electrical supplies that can be found in the East. The company has already closed several nice contracts, among which is one for wiring and lighting the Hotel Metropole for 1,500 lights, and has placed three direct coupled ventilating sets which will be arranged to run on three speeds. Instead of the usual annunciator they will use the Herzog Teleseme system, the first one in the city. Brass covered Interior Conduit will be used throughout.

The National Electric Company are wiring the Philadelphia College of Pharmacy, the residence of C. W. Bergner and many other smaller buildings. Mr. Warrell says business was never better than now.

The Pelton Water Wheel Company, of San Francisco, has several important contracts in hand for electric power transmission stations in the West, among which may be mentioned the Standard Consolidated Mining Co.—a plant of 250 h. p. capacity—the power from which is to be transmitted a distance of 13 miles to the mills of the Company, located at Bodie, Cal.; the People's Electric Power Company, at Aspen, Colorado—a 750 h. p. plant designed as a central distributing station for general mining use, involving a transmission of about three miles; and the Walla Walla Electric Light and Power Company, at Walla Walla Wash.—a 400 h. p. plant intended for light and power purposes—from which a street railroad is to be run; also a new 1,200 h. p. plant for the Roaring Fork Electric Light and Power Co., at Aspen, Colorado.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Miscellaneous, etc., will be found in the advertising pages.

THE
Electrical Engineer.
VOL. XIV. DECEMBER 7, 1892. No. 240.

THE BURKE CABLE RELAY AND TRANSMITTER.

THERE is probably no department of electrical work which has so nearly adhered to the original practice as that of cable telegraphy. Although it would be untrue to say that no valuable refinements had been introduced since the laying of the first cable, we can not recall a single radical departure from the original methods. This remark applies particularly to the working of long cables. More especially in the development of the cable relay and in automatic transmission, such as we find on land lines, has cable telegraphy remained almost stationary. When we consider the increased transmitting capacity which automatic transmission would allow of and the reduced time and cost of operation from substituting a relay for the hand re-transmission between land lines and cable and *vice versa*, now in vogue, it is not to be wondered at that earnest efforts have frequently been made to bring about a change in this respect.

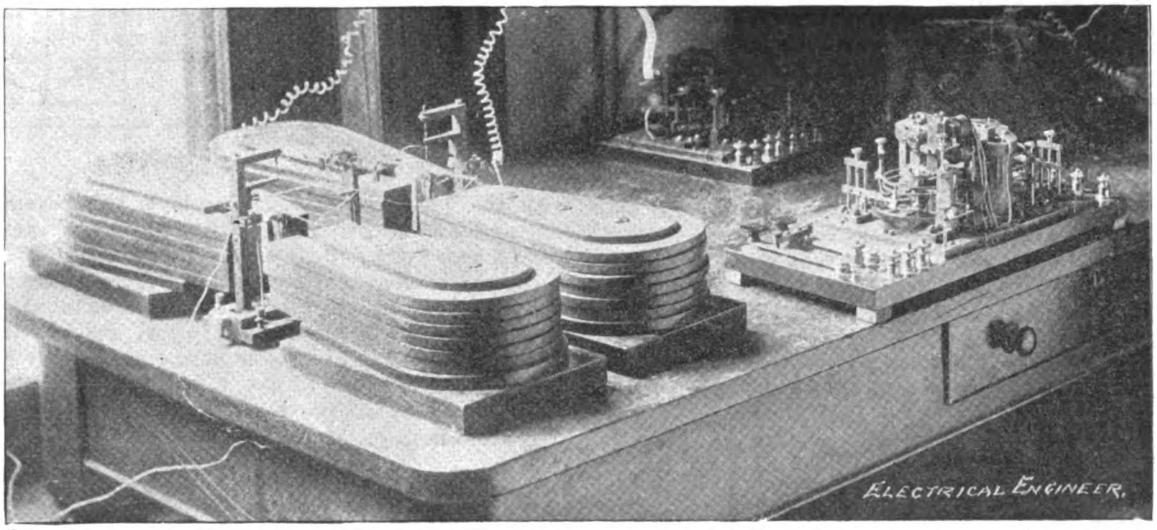


FIG. 1—BURKE CABLE RELAY AND TRANSMITTER.

Among those who have devoted their attention to this problem is Mr. Charles G. Burke, of this city, some of whose recent work is embodied in the apparatus we are about to describe. Mr. Burke has started out with the object of effecting cable transmission by means of the well known and simple Morse system, modified only in so far as to adapt it to cable working. His instruments consist of a novel relay and transmitter which are shown in the engraving, Fig. 1. The results obtained by him are well shown in Fig. 2, which is a fac-simile reproduction of the record made with the relay over the Direct United States Cable between Ballinskelligs, Ireland, and Halifax, Nova Scotia, the length of the cable being 2,640 knots.

The Burke relay by which the Morse record just referred to was made comprises two sets of coils, or what may be termed two compound coils, suspended in two independent fields of force created by four compound permanent magnets and a local circuit controlled by the movements of both sets of coils acting in unison. The arrangement is shown diagrammatically in Fig. 3. The coils constituting these compound coils E and F are set at angles to each other, so as to present in each compound four sides or poles. The angles of the coils and the inner lines of the poles of the field magnets, shown in the engraving, Fig. 1, are normally arranged to present such electric and magnetic relations to each other as that when the coils are energized by an electrical impulse, a rotary motion will be communicated to the coils around the line of their suspension and in a direction dependent upon the direction of the current. Like poles of the compound horse-shoe magnets illustrated are presented to each other. All the coils are connected in series so that the whole current is directed through each coil. The windings of the coils are so disposed as to produce a simultaneousness of co-operative action in the same direction.

Midway between the coils E and F is placed a standard C supporting two horizontal arms, L'', L'' through which is delicately pivoted a spindle L, bearing a contact arm L. The contact arm L is free to turn on its supporting spindle, but its motion is limited by an adjustable contact point or stop a and an insulated stop b. The extent of the motion or play of the contact arm L is designedly made as small as possible, and the tendency in one direction or the other of arm L is regulated by the adjustable springs N N. The arm M and stop a are terminals of a local battery R and this battery operates the sounder P, or other receiving or repeating instrument.

The coils E and F respectively support a rigidly affixed arm or bar of aluminum made as light as practicable and to ends of these aluminum bars J and J' are attached the silk threads K and K' extending on both sides from one bar to the other. The spindle L' of the local circuit standard C carries a similar aluminum bar or arm J'' and the silk threads K and K′ are made to pass beneath the ends of this bar J″ and are in frictional contact therewith.

By the adjusting screws A′ A′ the standards B and D, from which the coils are suspended, may be made to approach or recede from each other and the tension of the silk threads and the extent of their friction against arm J″ thereby be regulated. The contact arm L is free to revolve on its supporting spindle L′ by its adaptation to the fine screw thread cut on the spindle; a rubbing contact ensues from this motion and tends to prevent sticking at the local contact point. This freedom of motion of arm L contributes also to the more perfect freedom of the coils.

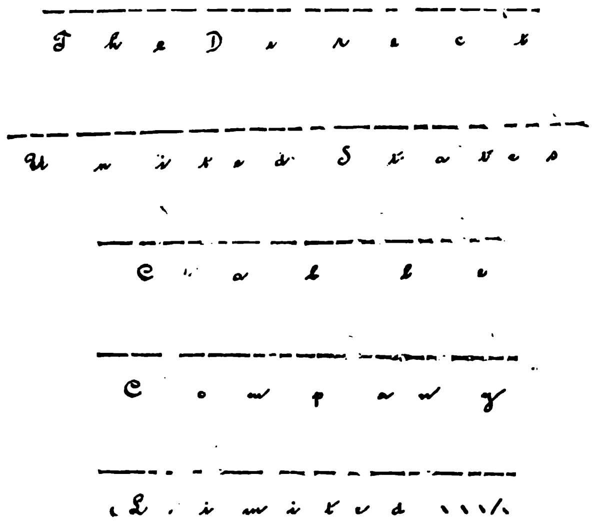

FIG. 2.

It will be noted that the coils of this relay are disposed where the field intensity of the magnets must exercise the greatest power, and that the coils are free to move in either direction and to the extreme limit to which a given direction of current can turn them. They are therefore able to follow the fluctuations of potential which always more or less attend all signals on cables, and to communicate all of these fluctuations to the contact arm of the local circuit and thereby reproduce on the receiving instrument the signals which caused them.

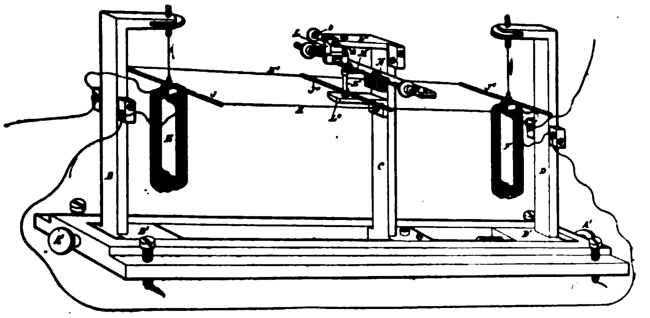

FIG. 3.

Recognizing the difficulties which grow out of any undue prolongation of battery contact in long cables, such as are, for instance, necessary under ordinary circumstances in making Morse dashes, Mr. Burke has devised a transmitter which comes in between the operator's key and the cable and which regulates the duration of battery contact with the line entirely independently of the operator. By this transmitter the static charge of the cable is made an auxiliary instead of an obstruction in Morse cable work.

The transmitter which is shown beside the relay on the table in Fig. 1, consists of a transmitting wheel or revolving contact maker mounted on the spindle B, Fig. 4; on the outer face of this contact making wheel and at regular distances thereon are cut angular shaped contacts E D, one side of each of these angular contacts being a right line. In direction of this right line of the angular shaped contacts two levers or contact brushes F and G are arranged and set so as to impinge upon the surface of angular contacts when the contact wheel revolves. These contact brushes are the terminals of the main batteries, as shown in the diagram Fig. 5, and control opposite polarities. They are independently adjustable upwards and downwards along the right line of the angular contacts so that they may be made to pass over a wider or narrower part of the contact surfaces and thereby increase or diminish the extent of battery contact with the line as the occasion may demand.

The contact wheel is normally held at rest by means of an escapement. The escapement pins J K in connection with the locking and releasing lever H″ prevent the contact wheel from revolving until the operator's key H′ energizes magnet G, by the power of local battery G″. One set of the escapement pins are insulated from the contact wheel which is in line, and the other set put the line to earth through lever H″ whenever the contact wheel reaches its normal position of rest, which is at the end of every completed signal. The function of key H′ is to release the contact wheel whenever the key is closed, and this key is operated as is usual in ordinary Morse work.

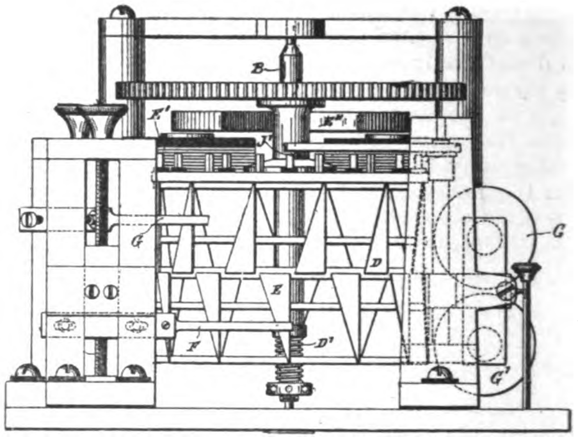

FIG. 4.

When lever H″ is released from the escapement pin with which it is engaged, the transmitting wheel advances one step and carries its contact surface under and beyond the battery controlling lever and thereby an impulse is sent into the line. As soon as this impulse has been completed, lever H engages an insulated pin on the transmitting wheel

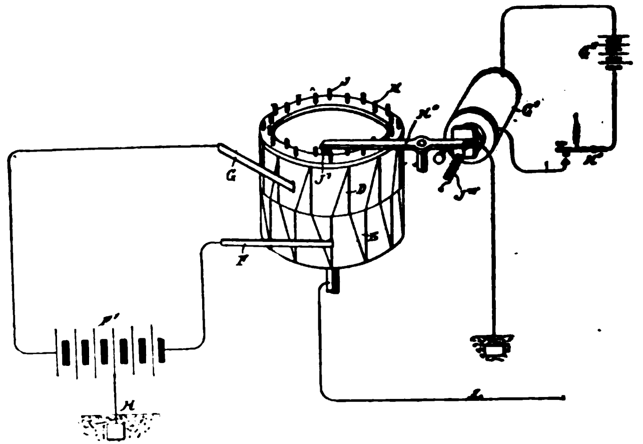

FIG. 5.

and arrests the wheel. The line at this point is insulated from both battery and earth and so remains until the operator opens his key and permits retracting spring J″ to release lever H″. As lever H″ becomes released the contact wheel advances another step and one of its contacts is carried under the brush or lever controlling the other pole of the battery, and by this means a current, the reverse of the former one, is sent to line and again the contact wheel is locked and the line put to earth.

It will be noted that the duration of these line contacts is not dependant upon the time the operator holds his key closed, and that he simply regulates the time when a marking current shall be followed by a clearing current. In the interval between these currents the static condition of the cable is analogous to an actual battery charge in so far as its effect on the receiving instrument is concerned, provided that the receiving instrument is sufficiently susceptible, and it is by means of this static condition that dashes are produced through this transmitter.

By this ingenious arrangement, Mr. Burke has entirely overcome one of the most serious obstacles to Morse work on long submarine cables.

ARC LAMPS FOR OPTICAL PROJECTION.

BY

Robert P. Dobbie

NOTWITHSTANDING the fact that an arc light is by far the best possible illuminant for optical projection, it has by no means come into general demand, and the few that are at present in use—mostly in colleges and similar institutions—show a want of study and specialization for the particular purpose for which they are intended. It is considered sufficient to shorten an ordinary street lamp, made for quite a different service, and to use it, in a great many cases, without even a focussing device.

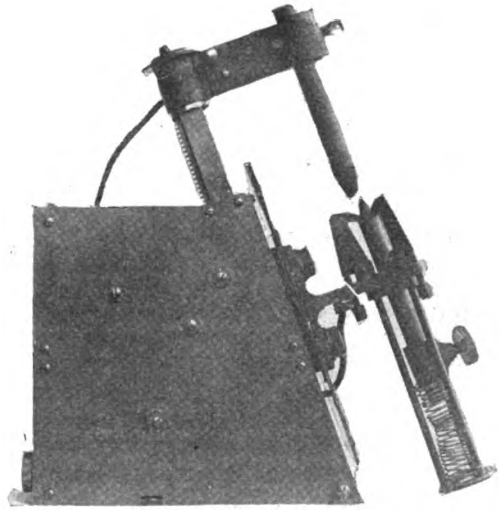

FIG. 1.—DOBBIE ARC LAMP FOR OPTICAL PROJECTION.

For an illuminant or "Radiant," as Mr. Louis Wright calls it in his excellent work on "Optical Projection," the following requirements are necessary: 1. Brilliance, or power and whiteness. 2. Steadiness. 3. Radiation from *one*, *small* surface. 4. "Radiant", to remain in one fixed position.

The arc fills all necessities as to the first requirement. Its quality and quantity are far superior to its nearest rival the oxy-hydrogen or lime-light; the latter is yellow compared to an arc, and under the most favorable circumstance 1,000 to 1,200 c. p. is the utmost that can be reached by it; 500 to 700 c. p. is far more usual, and is generally called a "good" light. This is measured straight in front and on the same level, and does not express the mean spherical value. An arc lamp, with 10 amperes, at 48 volts, will give over 2,000 c. p. (measured in the same way), and 15 to 25 amperes can be used if necessary, but which is seldom the case.

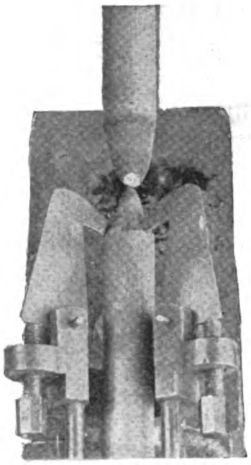

FIG. 2.

The second requirement, of steadiness, is not quite so easily attained by an arc lamp, but in the present state of the art steady dynamos, good carbons and proper appreciation of the conditions to be fulfilled, no trouble should be experienced.

The writer succeeded in showing the recent election returns at the Brooklyn *Eagle* main office, on the evening of November 8, with a lamp, shown in Fig. 1, using 18 to 20 amperes, and although the light was so powerful, flickering and flaming were absent. There were three 2,000 c. p. street lights within 40 to 50 feet of the screen, but they did not affect the view on the screen to a noticeable extent, while a projection from a lime-light stereopticon, a few doors up the street, was hardly visible under the same conditions. The same lamp was used in my recent lecture before the New York Electrical Society.

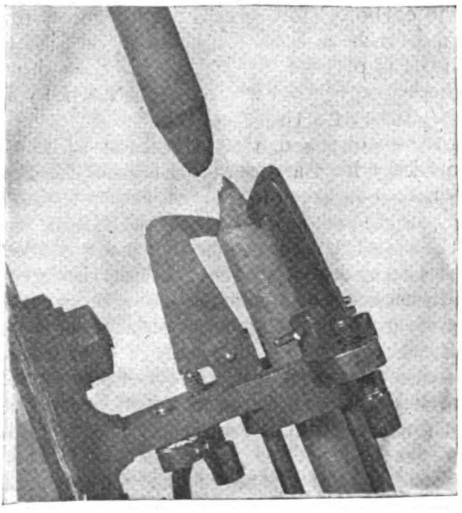

FIG. 3.

The third desideratum is easily met if the carbons are properly disposed. If they are vertical in relation to the condenser, the crater is not in the best position; even if the negative carbon is advanced toward the condensers, out of line with the positive, light will also proceed from the negative carbon as well as from the positive, thus making *two* sources of light instead of one, a condition fatal to fine definition on high-class work, such as microscopical subjects. If, however, the carbons are tilted about 20 degrees from the vertical, the luminous spot on the negative carbon is obscured from the condenser, and the crater on the positive carbon is presented in a most favorable way. Fig. 2 shows an engraving of the carbons, with the crater painted white. It will be observed that the crater squarely faces the front—that is, the condenser. Fig. 3 is a side view showing the luminous spot on the negative carbon, also painted white; but on reference to Fig. 2 it will be noticed that it is hidden from view.

Under these conditions, we practically have as radiant one surface about $\frac{1}{8}$ inch in diameter (the light proceeding from other parts of the carbon is very inconsiderable compared to that from the parts painted white), and this more nearly fulfils theoretical perfection—that is, a point, than any other illuminant; the lime-light, for instance, having a light radiating surface $\frac{1}{2}$ to $\frac{3}{4}$ inch in diameter, or from 16 to 35 times as large in area.

The last requirement is easily fulfilled, so easily, in fact, that I am surprised to find lamps without this provision—continuous manual adjustment of focus being necessary. The usual device is to fix both carbons in rack-driven holders that approach each other at proper speed. This is open to the objection that one particular combination of racks and gears, etc., is suitable to only one ratio of positive and negative carbon, and often to one particular make of carbon and strength of current.

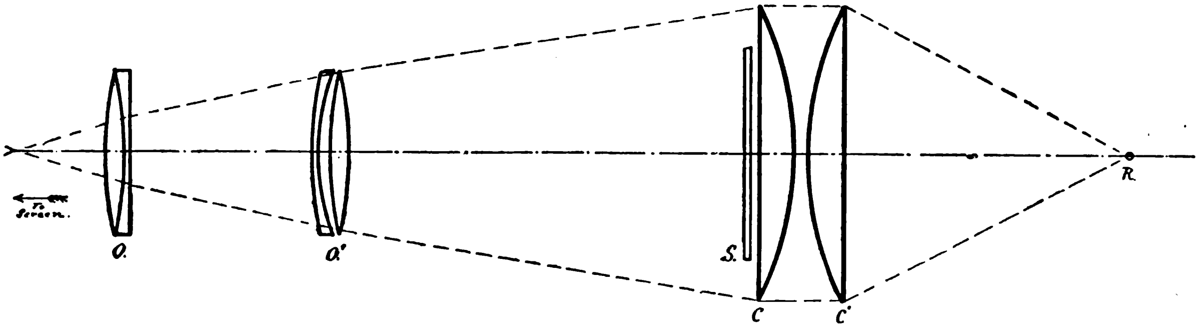

FIG. 4.—DIAGRAM SHOWING USUAL ARRANGEMENT OF OPTICAL LANTERN.

The device shown in Figs. 2 and 3 is one that I have found to work perfectly, and which does not possess this defect. The carbons abut against three points or hooks, set together in a circle a little less than the diameter of the carbon, which is pressed up by a spring, as shown in Fig. 1. As the carbon wears away it is fed up by increments of $\frac{1}{6}$ to to $\frac{1}{32}$ inch at a time.

It might be supposed that the heat of the arc would melt the hooks, which are made of copper; but in practice they do not, as conduction and radiation come into play, the hooks being specially designed with that end in view. I have attempted to construct a lamp with *both* carbons operated in this manner, but the positive side gives trouble; if the arc flows for an instant the points are gone, but in careful hands good results can be obtained. In the accompanying engravings, reproduced directly from photographs, I have painted the crater white in order to show clearly how it is presented to the condensers, and have also placed a white spot on the illuminated part of the negative carbon, which can be seen in the side view, but is obscured.

I have also thought it well to add here a sketch in the sectional view, Fig. 4, showing the usual arrangement of an optical lantern. Here, R is source of light or "radiant"; C C¹, the condensers; S, the slide; and O O¹, the objective.

It is very common to use triple condensers, but the results obtained from them are inferior to the ordinary double plano-convex arrangement, shown in Fig. 4, at C C¹, and for the following reasons:—The arc is too close to the anterior surface, and breakage is frequent. The color correction is no better, and the gain of light is insignificant, as the marginal rays, striking the condenser at an obtuse angle, are reflected instead of being refracted and transmitted, and the distribution of light over the slide S, is uneven.

The disposition of the carbons, and the method of feeding the negative carbon, are from 30 to 40 years old, and I disclaim any "new idea" or "great invention" in this apparatus. But I do wonder that the essential requisite of presenting the crater of the positive carbon has not been better understood and applied, and that such a simple device as the spring feed of the negative carbon, so old, has not been more generally used.

A NEW METHOD OF FIELD EXCITATION.

BY

H. L. Tyler.

ALTHOUGH the dynamo of to-day is a grand achievement, it possesses numerous disadvantages, and in attempting to obviate these the unipolar type of machine invariably suggests itself as the ideal, because it generates a continuous current and needs no commutator to enable it to excite its own magnets. It may be truthfully said that this is its only great advantage in view of the fact that for distribution the alternating current is preferable. But, whatever may be said in favor of the above machine, the results of years of experiment have given rise to the general conclusion that "it is impractical to construct an efficient self-exciting dynamo of uni-polar design." In constructing a generator the three most desirable attainments in the abandonment of the commutator are: Reduced first cost; no complicated parts; and freedom from sparking. The evil effects of the latter are too prevalent and too well known to be mentioned.

For a long time the writer has been at work on a machine designed to overcome at least some of the bad features of ordinary dynamos, and one has been produced embodying the desirable points above noted, although it is not a unipolar generator. The engraving Fig. 1 shows the machine in perspective, while Fig. 2 shows its construction diagrammatically. As will be seen the dynamo is of the stationary armature type and the method of exciting the inner revolving field constitutes the novel feature. The exciting current is fed to the field through the pole-changer shown in Fig. 2. The "changer" receives an alternating current and alternately feeds the fields, the four sections of each ring being only the terminals of the field coils, and not for the purpose of delivering the current in a uni-direction to the fields. In fact, the pole-changer delivers the current practically in the same state (alternating) as it is generated.

In Fig. 3 as the north magnet pole passes the armature coil at D the current from this coil enters at field coil terminal 1, passing around poles N¹ and N², leaving at terminal 2^a. Therefore, the lines of magnetic force are forced outward at N^1 and N^2 and drawn in at S^1 and S^2. When the south pole comes before the armature coil the current of course reverses, and as the pole-changer has made a quarter turn the current enters the field coil at 3, passing around poles S^1 and S^2 and leaving at 4^b,—producing the same magnetic polarity in all four poles as resulted when the current was in the coils of poles N^1 and N^2.

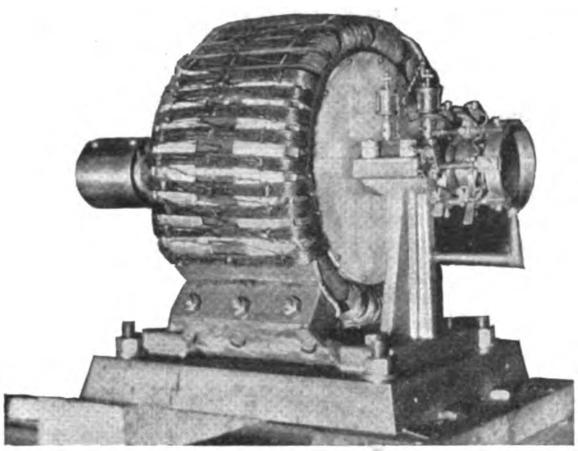

FIG. 1.—THE TYLER NON-COMMUTATING DIRECT CURRENT DYNAMO.

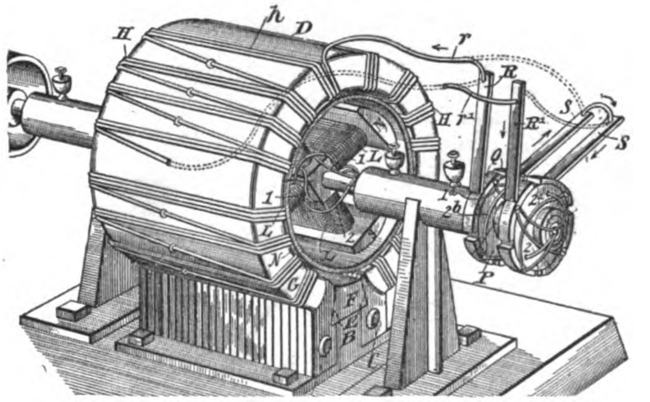

FIG. 2.

This method of field excitation at first appeared impractical; but I have repeatedly tested it with gratifying results. There is no sparking whatever, even on a dead short-circuit. The dynamo is made absolutely noiseless by a thin non-magnetic casing encircling the fields.

There are any number of ways to place the armature coils, but it appears unnecessary to designate them here.

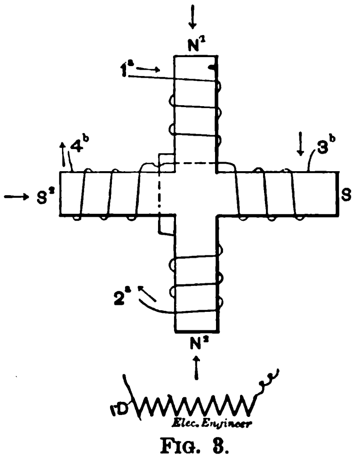

FIG. 3.

The general nature of the machine admits of first-class construction at a surprisingly low cost and its high efficiency and simplicity are among its best commendations.

THE FIRST ELECTRICAL TREATISE OF GALVANI.

BY

Park Benjamin

THE first publication on the subject of his electrical discoveries was made by Galvani in Volume 7 of Antichi Commentarii del Instituto di Bologna, in 1791. Prior to that he had printed four memoirs or treatises, mainly on medical and chemical subjects, entitled as follows: "De Ossibus," "De Renibus," "De Manzoliniana Supellectili" and "De Volatilium Aure."

Apparently coincidental with the appearance of the volume of transactions above named, Galvani's essay, "De Viribus Electricitatis in Motu Musculari," was printed by the Bologna Institute separately; but only a very few copies were thus issued. In 1841 the Institute received, by bequest from Galvani's son-in-law, Aldini, quite a number of Galvani's papers and manuscripts, and in that year it caused to be published, under the editorship of Professor Gherardi, a complete collection of all of Galvani's writings. In commenting on Galvani's essay separately, issued in 1791 at Bologna, Gherardi refers to it as of the most extreme rarity. The edition of Galvani's "De Viribus," which is ordinarily considered the first, is dated 1792. It was published in Modena, and it contains a commentary by Aldini and a long letter to Carminati. There is only one other well-authenticated treatise, which was published by Galvani during his lifetime, namely, that on "Animal Electricity," addressed to Spallanzani in 1797. There are two doubtful treatises on "The Conducting Arc," published in 1794, concerning which it is uncertain whether they were the work of Galvani or Aldini.

The Royal Society catalogue credits them to the latter. The Ronalds catalogue, as usual, blunders concerning all of this. It leaves out all mention of the 1791 issue and reports the existence of an essay entitled "Propositione de Electricitate" under date of 1786; and, to make matters worse, asserts that such an essay is in the Ronalds collec-

Rei novitatem ille admiratus de eadem statim me alia omnino molientem, ac mecum ipso cogitantem admonuit. Hic ego incredibili sum studio, & cupiditate incensus idem experiundi, & quod occultum in re esset in lucem proferendi. Admovi propterea & ipse scalpelli cuspidem uni vel alteri crurali nervo, quo tempore unus aliquis ex iis, qui aderant, scintillam eliceret. Phænomenon eadem omnino ratione contigit; vehementes nimirum contractiones in singulos artuum musculos, perinde ac si tetano præparatum animal esset correptum, eodem ipso temporis momento inducebantur, quo scintillæ extorquerentur.

At metuens, ne ii ipsi motus a cuspidis potius contactu, qui pro stimulo forte esset, quam a scintilla orirentur, eosdem nervos iterum eadem ratione in aliis ranis cuspide tentavi, & quidem gravius, quin ulla tamen scintilla tunc temporis ab aliquo eliceretur; at nulli omnino visi sunt motus. Hinc mecum ipse putavi, forte ad phænomenon inducendum & contactum alicujus corporis, & scintillæ jactum una requiri. Quamobrem scalpelli aciem iterum nervis apposui immotamque detinui, tum quo tempore scintilla extraheretur, tum quo tempore machina perfecte quiesceret. At phænomenon educta dumtaxat scintilla prodiit.

Experimentum iteravimus eodem semper scalpello adhibito: verum non sine nostra admiratione interdum educta scintilla recensiti motus contigebant, interdum deficiebant.

FAC-SIMILE OF A PAGE FROM GALVANI'S FIRST ELECTRICAL TREATISE.

tion, and that it was published at Bologna. If the Ronalds library does possess such a work, it is singular that the Institute of Bologna should know nothing about it and should carefully refrain from making any mention concerning it in its very voluminous and elaborate publication of all of Galvani's writings. The statement is probably about as accurate as the accompanying one, to the effect that Galvani died in 1789; a period during which he was very much alive and busily engaged on some of his most important work. If the Ronalds catalogue could be properly edited, students of electricity, the world over, would be greatly benefited.

Judging from a moderate experience in collecting the rarities of electrical literature, I am inclined to believe that there is nothing more scarce than this first work of Galvani. The copy in the possession of the writer is, of course, unique, for it contains the corrections made by the philosopher's own hand, which I find, by comparison, were incorporated exactly as here directed in the following edition of 1792. Accompanying this is a fac-simile reproduction of p. 4 of the work, in which Galvani describes his historical experiment with the frog, and of which a translation, in part, is given below:

> I dissected a frog, and prepared it as in Fig. 2, Plate V., and, putting it on the table on which was the electrical machine (Fig. 1), I placed it wholly disconnected from its conductor, and separated from it by an interval not short. One of those who were assisting me in the work lightly touched by accident, with the point of the scalpel, the internal nerves D D in the legs of the frog, when all at once every muscle of the joints was seen to be contracted, so that they seemed to have fallen into the most vehement and violent convulsions.

I have just received the book from Italy. The handwriting of Galvani needs no authentication, although I have it well authenticated; for comparison of it, letter by letter with the fac-similes of Galvani's manuscript published by the Bologna Institute, leaves no possible doubt that the writing, in both cases, was made by the same hand.

These books come to light, nowadays, only apparently when some one dies and a library is scattered. This seems to have been the present state of affairs; for the intelligent book detective whom I have in Italy sends me at the same time the original publications of Salvator Dal Negro, Pivati and others, none of which seems to have got into the general book market.

While on the subject of scarce electrical works, and as the aim of every electrical collector is a copy of the original Gilbert (1600), it may be of interest to add that this book is appearing in numbers which make it less of a rarity than it was regarded some years ago. There are probably a dozen copies in this country. The editions of 1628 and 1630 are more scarce than the first edition, and the posthumous work of Gilbert (1651) is rarer than either. A fac-simile copy of the 1600 edition has just been published in Berlin, and the first English translation will shortly be published in this city, thus forestalling the much be-trumpeted effort of the English Gilbert Society.

And that, by the way, reminds me to suggest that electrical genius is represented in Central Park only by an exasperating statue of Morse—not as bad, it is true, as that of Halleck with his head screwed on, or Scott with the mansard cranium, or Burns leaping from the painful tack—but still a horror. There ought to be another statue there mating that of the friend and contemporary who wrote into his plays the medical knowledge Gilbert taught him. The poets and actors have erected a statue of Shakespeare on our great pleasure ground; cannot the electricians put beside it one of Gilbert?

THE HAZELTINE DOUBLE-PLATED CARBON.

Various devices have been proposed for prolonging the life of carbons in arc lamps and enable a single-arc lamp to burn all night or to perform the functions of a double-arc lamp and to effect a material saving in carbon and in labor in trimming.

Mr. C. W. Hazeltine, of St. Louis, Mo., has recently discovered that by coating the carbons with copper, of about the same thickness as that usually employed, and then with a heavier coating of zinc, the carbons can be made to burn nearly twice as long as with merely the copper covering. Several theories are advanced by the inventor to account for this, one being that the heat of the arc forms oxide of zinc which permeates the copper coating, closing its pores and preventing the access of cold air; and another, that the zinc oxide, covering the copper, protects it and prevents its burning away above the arc.

The oxide of zinc, though infusible, is readily carried away into the air, or forms a slight deposit at the bottom of the globe.

Other combinations of metals have been experimented upon by Mr. Hazeltine with good results.

THE NEW LUNDELL MOTOR.

Our readers will remember the description which we published some months ago of the Lundell fan motor. This machine was characterized by the novel design embodied in its magnetic circuit, the field being of the iron-clad type, and energized by a single coil. The success obtained with this small machine, which was built by the Interior Conduit and Insulation Company, of this city, was such as to warrant the application of the same principles to larger sizes, and as a result Mr. Lundell has now worked out a series of motors ranging in size from ¼ h. p. to 10 kilowatts, in which the same principles are applied, and additional improvements have been introduced.

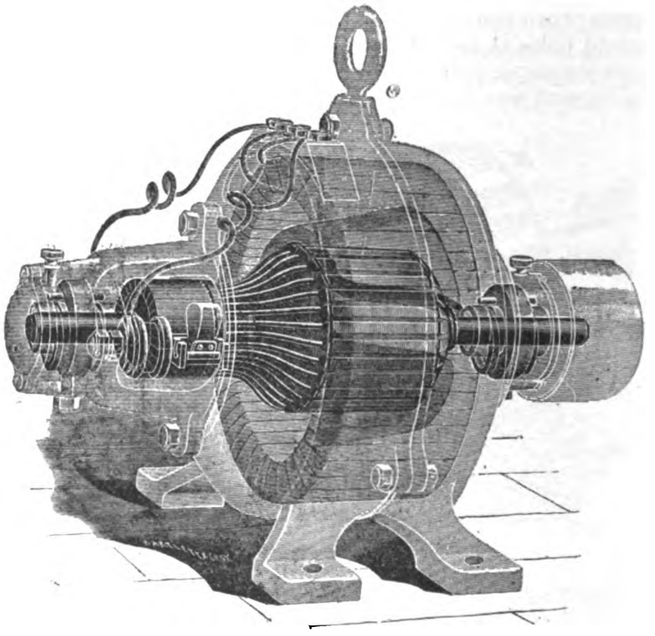

Fig. 2.—Skeleton View of New Lundell Motor.

The machines of larger power are of the general form illustrated in the engraving, Fig. 1. The arrangement of the fields and energizing coil is very clearly shown in the illustrations, Figs. 2 and 3, the latter showing the two halves separated with the energizing field coil between them. While the spherical form of field was eminently adapted to small fan work, it is evident that when it is desired to attach the motor directly to a pump, or other device, the cylindrical is better adapted as being somewhat more compact and admitting of a shortening of the machine, so that it occupies less space.

In the present construction, it will be noted that the magnetic shell also completely protects the armature; and the whole shell is utilized in the magnetic circuit. It has been so designed that the cross-section of the shell equals the cross-section of the base of the pole-pieces, so that no choking of the lines of force can occur at any point. The adoption of the single energizing coil not only reduces the construction of the machine to the simplest point, but by having only two terminals it is specially adapted to be placed in the hands of inexperienced users, as it avoids any possible mistake in connecting up or any bother or delay in examination when such becomes necessary. Another feature of the design adopted, it will be noted, is that the pole-pieces can be magnetized directly, while, to a large extent the direct magnetization of the armature is also accomplished, so that a considerable economy in the ampere terms of the energizing coil is thereby affected.

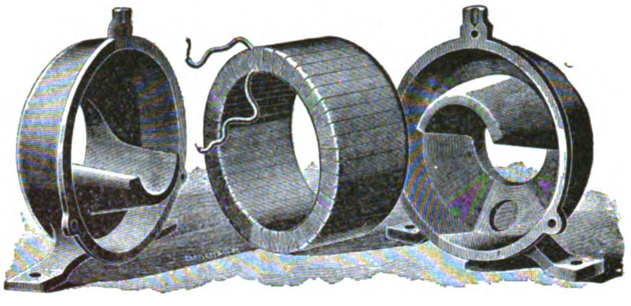

FIG. 3.—FIELDS AND ENERGIZING COIL.

In designing the armature of these machines, Mr. Lundell has adopted the Pacinotti form, Fig. 4. This type of armature has in the past been subject to unfavorable criticism on account of the resultant heating of the pole-pieces, but it is now pretty well recognized that this heating was not due to the Pacinotti ring itself, but to the lack of knowledge with regard to its proper design. A little reasoning will show that when the ratio of the distance between the teeth and the magnetic gap is too small, a concentration of the lines of force will take place so that the pole-pieces will be swept over alternately by sections of the highly concentrated lines of force, and by practically inert material. The result is that Foucault currents must inevitably be set up in the pole-pieces and cause the heating, which has been noted in the past. By so proportioning the teeth, however, that the lines of force emanating from the pole-pieces are more evenly distributed over their entire surface surrounding the armature, this abrupt demarkation is avoided, with the result that Foucault currents are also avoided in the pole-pieces.

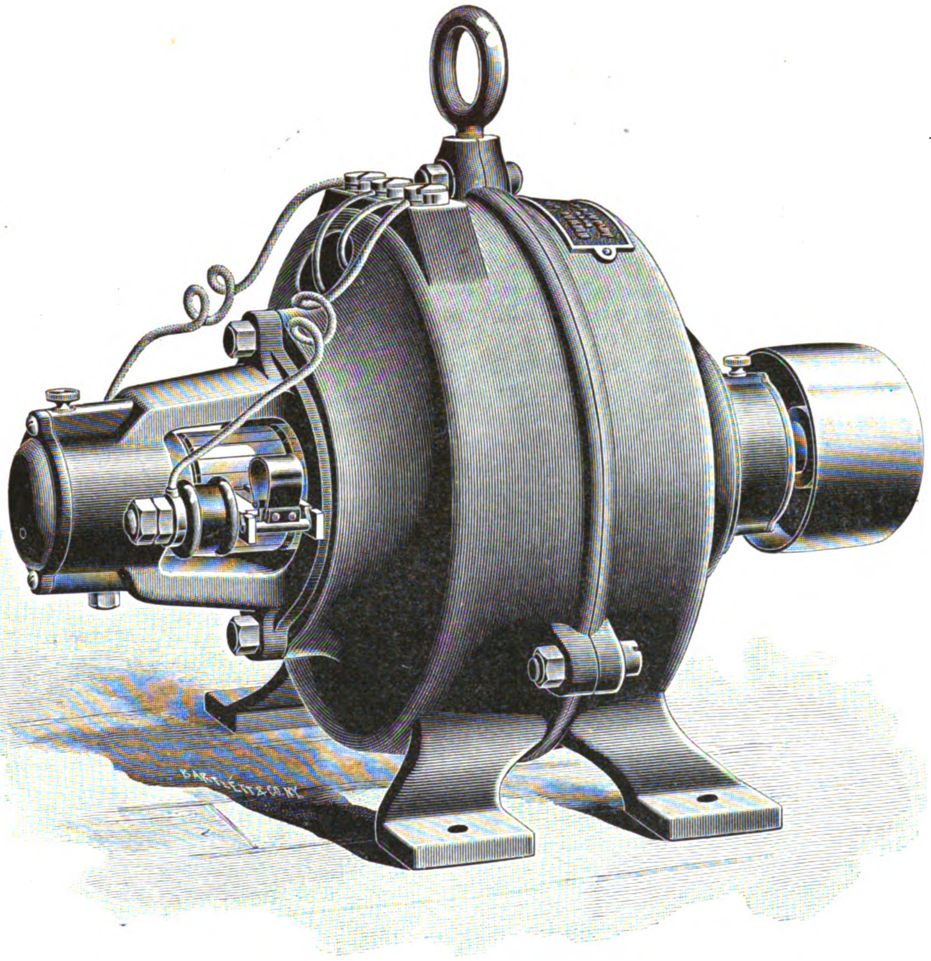

FIG. 1.—THE NEW LUNDELL IRON CLAD MOTOR.

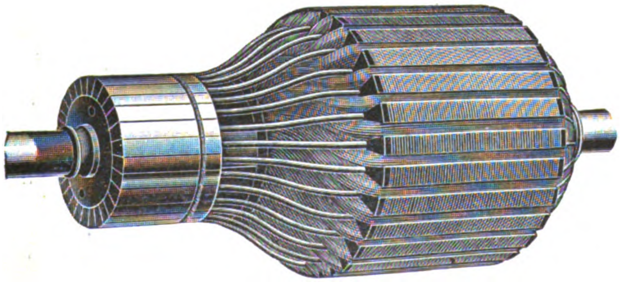

FIG. 4.—ARMATURE OF LUNDELL MOTOR.

The result of actual practice with the Lundell machine has shown the soundness of this theory, which is carried into practice by the employment of deep and narrow slots. The mechanical design of the machine has also been carefully worked out.

Notwithstanding the iron-clad nature of the machine, the concentric position of the field coil allows the armature to be withdrawn without disturbing either the field coil or the pole-pieces. The commutator is also well protected between the two limbs of a broad, strong bracket.

A very ingenious spring arrangement for pressing the carbon brushes against the commutator has been devised

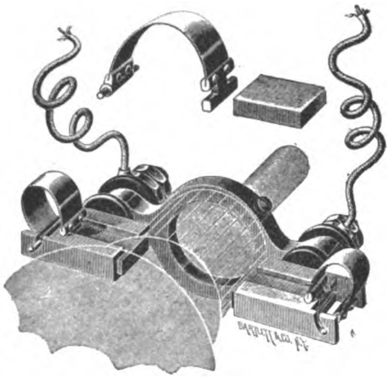

FIG. 5.—LUNDELL BRUSH HOLDER.

by Mr. Lundell, and is shown in the engraving, Fig. 5. The spring which is shown enlarged in the upper half of this engraving, has its rear end placed in a curved slot at the end of the brush holder; while its forward end in the shape of a T presses against the carbon which slides in the ways in the brush holder. To remove the carbon, it is merely necessary to press the spring upwards out of the slot which releases it, so that the T can be withdrawn, and the carbon slides out.

Recognizing also the necessity of continuous lubrication, Mr. Lundell has designed an ingenious oiling arrangement shown in the engraving, Fig. 6. The oiling is accomplished by means of a number of rings which encircle the shaft and dip into the reservoir, thus continually feeding fresh oil to the bearing. In order that the attendant may know the exact condition of the oil a simple oiling device has been added, consisting of a double elbow with an oil chamber and rising slightly above the normal level of the oil.

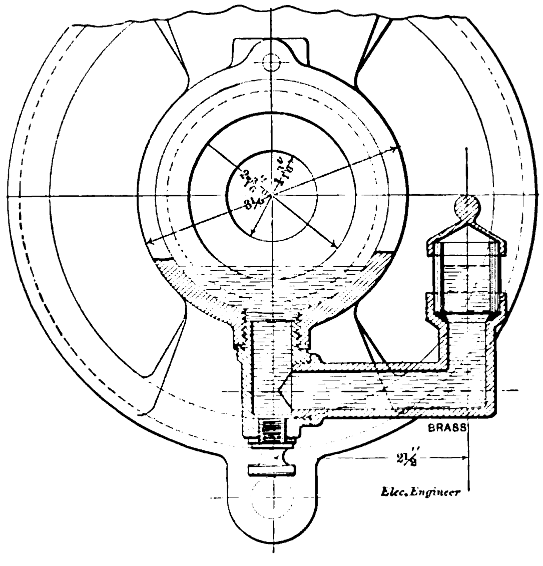

FIG. 6.—LUNDELL OIL RESERVOIR.

The vertical arm of this elbow has been so arranged that the normal height of the oil corresponds exactly with the level of the top of the elbow, so that by no possible inadvertency can the attendant pour in oil sufficient to flood the bearing and cause the oil to run out at the inner surface of the shaft and so go into the armature. This visual gauge arrangement is provided with a short length of glass tube. When the oil is on a level anywhere within the compass of the glass tube it is an indication that the amount provided is sufficient for lubrication, so that the attendant cannot be left in doubt as to the proper quantity of oil required.

These machines, which have been carefully worked out in all the details, are wound for any circuit, and are exceedingly compact for their power.

INCREASED COMMERCIAL EFFICIENCY AN HIGHER ECONOMY IN CENTRAL STATIONS.—IV.

(*Conclusion.*)

BY

J. H. Vail

COMMERCIAL EFFICIENCY.

LET us keep prominently before us the fact that a small percentage of gain per horse power hour may be more than compound interest on extra investment, and *that the saving on the total horse power hours of a year's output will aggregate a large sum of money earned.* In considering commercial efficiency, we must not be satisfied with better efficiency of the dynamo engine, or boiler, but we must calculate on larger increased commercial efficiency of the entire improved central station as a unit when compared with central stations of existing and less efficient types.

Higher commercial efficiency is to be obtained by refinements of details, more accurate proportions of parts, greater perfection in mechanical details of manufacture, a more scientific combination of apparatus, and general high-class construction of the entire plant. The higher commercial efficiency of generating units will also be gained through using larger high class dynamos coupled direct on engine shafts, the engines being of the compound or triple-expansion type. To obtain this increased commercial efficiency of the entire station and system, we must investigate the merits of the individual boiler, engine, dynamo and system of distribution, that we combine to form the entire equipment.

As an illustration, we will assume that in the town of "A" the electric company have installed their plant and operate it under the following conditions: With boilers of low evaporative efficiency. With coal of poor steaming qualities. With loss in steam pressure between boilers and engines, due to small size of pipes, frequent bends and insufficient covering. With engines requiring 35 to 50 lbs. of water per horse power hour as well as excessive internal friction. With belted dynamos of 80 to 85 per cent. efficiency. With line construction of such high resistance that there is a loss of 20 to 40 per cent. between station and consumer.

Such a combined station cannot fail to be very low in its net commercial efficiency. In the town of "B" the installation comprises: Boilers that in daily practice have high evaporating qualties. The coal used gives the greatest evaporation of water per dollar expended. The steam piping is of ample size, free circulation, well covered, loss between boilers and engines reduced to the minimum. The engines are of high efficiency. The dynamos at least 90 to 93 per cent. efficiency. The loss in line distribution not more than 10 to 15 per cent. With the above aggregated, it is easy to see that the commercial efficiency of the entire plant and system in town "B" must be far superior to that in town "A," and yet in neither place have I assumed the use of any special appliances for saving coal or water.

A few words as to commercial efficiency of generating units. The highest efficiency heretofore obtained has been with the high speed engine belted to bi-polar dynamos. This combination frequently does not exceed 70 per cent. and when attaining so high as 75 per cent. is considered at best average maximum commercial efficiency. It will readily be understood that the more shafting and belting we introduce between the engine and driven dynamos, the greater the loss through friction and, as a consequence, the commercial efficiency is reduced. We should therefore aim to apply the driving power in the most direct manner possible. This can only be accomplished by mounting the dynamo armature direct on the engine shaft, thus avoiding all intermediate appliances.

The following data, obtained from tests of triple expansion engines and direct driven dynamos, will be interesting as showing the improvement in commercial efficiency as the load increases.

Comparative Commercial Efficiency of 2 x 50 K. W. Generator Under Various Loads.

Fields charged. Friction load.	Load—Watts.	Electrical horse power.	Indicated horse power.	Commercial efficiency.
				Full speed.
18.22 h. p...	1,100	1.47	18.22	
	11,900	15.95	33.41	47.7 per cent.
	23,900	32.	51.32	62.5 “
	35,850	48.	69.40	69.1 “
	48,000	64.34	91.58	70.2 “
	60,250	81.	113.2	71.5 “
	72,650	97.38	130.9	74.3 “
	85,400	114.47	148.13	77.2 “
	109,550	133 44	166.3	80.2 “

Comparative Commercial Efficiency of 2 x 200 K. W. Generator Under Various Loads.

Friction load.	Load.		Electrical horse power.	Indicated horse power.	Commercial efficiency.
	Amp.	Volts			
					Full speed.
105.3 h. p...	400	126	67.7	198.0	34.2 per cent.
	800	126	135.0	381.0	25.2 “
	2,600	124	432.1	561.8	76.9 “
	2,932	126	479.1	614.6	77.9 “
	3,100	125.5	521.5	631.6	82.5 “
	3,400	125.	569.	664.	85.6 “

I have no doubt that an actual commercial efficiency above 90 per cent. will eventually be attained by further improvements in direct driven generators.

The above tests make three points clearly worthy of attention :

1st. That 100 h. p. is too small a capacity for economical service from a triple-expansion engine, because, while it costs much in excess of the simple high pressure engine and belt driven dynamos, its commercial efficiency shows only 75 per cent., being on a par with the commercial efficiency of the latter class of plant.

2nd. That below half load, the generators of either size show too low in commercial efficiency to warrant their use under small load.

3d. That in units of large size, we attain an efficiency above 82 per cent., and that the efficiency will increase with size of unit.

The higher commercial efficiency gained will more than compensate for the better class and cost of engineering talent, which will be required to design these new stations, as well as the higher grade of skilled engineers required to operate the improved type of station.

ON A METHOD FOR BALANCING ARMATURE REACTIONS.[1]

BY HARRIS J. RYAN.

THE generators or motors are constructed in the ordinary manner except that holes are bored through the pole-pieces immediately back of the surfaces through which conductors are wound in sufficient number and in such a manner that the armature current passing through them shall oppose and equal the magnetizing effects in the armature conductors at all points. This method was suggested as early as 1886, but was never practically demonstrated until three years ago, when the author applied it to actual designs. During the past two years investigations of its practical application to actual machines have been conducted by him, and, with the assistance of Mr. M. E. Thompson, fellow in electrical engineering at Cornell, six machines have been designed, two of which are already constructed, each representing a distinct line of practice.

Very satisfactory results were obtained with both machines experimented upon, the second of which will be considered to show the results thus far obtained. This is a four pole incandescent dynamo for which the following data are given :

Output, 40 amperes at 100 volts and 1,200 r. p. m. Type of machine, 4-pole ; field of cast iron in two pieces. Armature: drum winding through 58 grooves; 5 No. 10 B. & S. G. wires in each groove ; winding in two circuits ; 29 commutator bars ; grooves milled out, size $\frac{5}{8}$ in. x $\frac{9}{64}$ in.; outside diameter of core $7\frac{1}{2}$ in., inside 3 in., built up of discs; surface of completed armature wound with No. 14 B. & S. G. iron wire. Length of armature and poles, 6 in. each. Effective length of iron in armature core, 5 in. Magnetic leakage, 15 per cent. Field cores, 5 in. x 2 in., with rounded ends; area 9.14 sq. in. Mean length of field magnetic circuit, 12.5 in. Magnetic density in the armature core, 5,400; in the air gap, 4,900; in the armature lugs, 8,400; in the field cores, 6,800. Field winding: mean length of a turn, 15 in.; requisite exciting M M. F. for field circuit, 910 ampere turns; for armature, 25 ampere turns; for air gap, 1,000 ampere turns ; or a total of 1,935 ampere turns; requisite size of wire for excitation at 100 volts, 1,575 cir. mils.; size of wire adopted, No. 18 B. & S. G., enough being used to bring down the exciting current density to 1,000 cir. mils per ampere. Total weight of machine : 400 pounds.

The number of balancing conductors on each pole face is found as follows : Armature conductors under a pole × current in the pole = balancing conductors back of each pole face × total armature current through them.

The ordinary pernicious effects of so short an air gap with a comparatively large number of ampere turns are not observed in this case, and the machine acted exactly as theory shows that it should if armature reaction were absent. The poles covered 90 per cent. of the armature circumference so that the back ampere turns were negligible. When separately excited, the machine could be loaded down to 100 amperes when the drop in E. M. F. at the brushes was no greater than that due to the ohmic resistance of the armature. The neutral point was not shifted. When self excited the lowering of the field excitation produced a little more drop, while the magnetic density in the air gap was found to be the same at normal load as at no load.

Operated without the balancing coils, even at a speed of 1,800 instead of 1,200 revolutions, it was impossible to get a greater output than 37 amperes at 85 volts, for, considered as an ordinary machine, there is too little material in the field cores, poles and winding and too great a number of ampere turns on the armature.

Cross induction may be entirely avoided, or even reversed in its effects by the use of the balancing coils ; the magnetization through the poles, air gap and armature does not undergo a redistribution under any load ; the armature current does not alter the total magnetization through the armature at any value ; the neutral point remains constant ; the diameter of commutation with metallic brushes changes only by the small amount necessary to balance the self-induction of the commutated section by the field in which it is moving ; regulation for constant current may be effected without change of the diameter of commutation by varying the magnetization through any limits. By proper designing, the output for a given weight in the completed machine may be quite largely increased over that which is realized in the common practice of to-day, and the air gap may be made as small as mechanical requirements will permit without changing the performance of the machine, thus enabling one to realize practically the advantages of differential excitation that is utilized so successfully in the modern alternate current transformer.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* The Electrical Engineer. *Communications for the attention of the editors should be addressed,* Editor of The Electrical Engineer, 203 *Broadway, New York City.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

Vol. XIV. NEW YORK, DECEMBER 7, 1892. No. 240.

Truisms which one has verified for one's self out of a personal experience are apt to have a special value to the owner.—S. P. Langley.

NOT ABSORPTION, BUT COMPETITION.

THE sporadic rumor of an early absorption of the Westinghouse Company by the General Electric Company has again found some lodgment in electrical circles during the past week. Aside from the emphatic denials of leading officials of both companies, abundant reason for discrediting the report is to be found in the present circumstances of the Westinghouse Company. The golden opportunity of the capitalists and organizers who formed the General Company for acquiring the property and business of the Westinghouse Company would seem to have passed a little over a year ago, when it was hard pressed and before its successful reorganization. Its prosperous business for a twelvemonth and the prestige acquired through its World's Fair contract have put the company in a position of independence hardly to have been expected from the outlook in the autumn of 1891. To the success of the General Company in maintaining the Edison Lamp patent in the court of last resort, the Westinghouse Company promptly responded by announcing the early introduction to the market of a new and non-infringing lamp at a great reduction from prevailing prices. Through the daily press and in the advertising columns of electrical journals it now quotes prices and offers to fill orders from and after January 1, 1893. The rates named, viz.: 30 cents for 16, 10 and 8 c. p.; 35 cents for 25 and 20 c. p. with discount of from 2½ to 10 per cent., according to quantity, are indeed surprisingly low. The lamps' advent will naturally be eagerly looked for by consumers, and, perhaps, with mixed feelings by other lamp manufacturers, including the General Company. Supplementing his low prices, Mr. Westinghouse offers a further advantage in an allowance of 10 cents each for every unbroken burned-out lamp returned to the factory. Mr. Westinghouse estimates the saving over existing rates thus open to central station companies as equal to one per cent. on their capital stock. Even if that estimate be too high there can be no doubt that a supply of satisfactory lamps at the quoted rates and terms would effect a very large saving to operating companies and other consumers.

The energetic competition of the Westinghouse and other companies with the General Company is a most gratifying and encouraging feature of the present situation of electrical industry. The danger apprehended by many of the successful establishment of a gigantic and comprehensive monopoly, combine or "trust," can best be avoided not by denouncing the General Electric Company, but by effectively resisting it on economic principles and by business methods.

500-VOLT MOTORS.

In most of our cities, motors are now run chiefly on 110 or 220 volt circuits, a few being found also on arc series circuits. There appears to be, however, a marked tendency towards the use of constant potential motors, at as high a voltage as 500, not merely on railway circuits, but in regular power work. Mr. A. C. Balch, the electrical engineer of the Union Power Company of Portland, Ore., writes us that they now have in operation something over 700 h. p. of 500-volt motors. It would, he remarks, be a financial impossibility to run at any lower voltage, as the station is three miles from the centre of distribution. The 500-volt machines have given little, if any, extra trouble as compared with the 110 or 220 volt motors.

This is interesting and encouraging, and is confirmed by the reports that reach us from another large city, where about 850 h. p. nominal is now being furnished with 500-volt motors, averaging 7½ to 10 h. p., and going up to 25 h. p. In this case, the station is about midway in a system of distribution stretching 5 miles, or about 2½ miles each side of it. The demand is growing, and the motors will reach 1,000 h. p. daily this year. As overhead circuits are used, the extensions of the service are made quickly and economically. Current is metered, and also sold at a flat rate, but prices, so far as we can learn, average four or five cents per horse power hour, and perhaps shade below that for large powers, running however, well up to ten cents for small powers.

We think the field here indicated is worthy of study by station managers. Motors of high voltage are now well built, and even in the smallest sizes are capable of yielding excellent results; while the saving of copper in the circuits is something enormous. But perhaps we shall not see the full possible development of this field until a higher volt incandescent lamp also makes its successful début. Meantime, in planning independent power circuits, managers should, we think, concentrate their energies and attention on 500-volt work, as being safe for the public, as more economical for themselves, and as admitting of the distribution of power over a much larger territory.

ELECTRIC RAILWAY DEPARTMENT.

THE LAKE ROLAND ELEVATED RAILWAY, BALTIMORE, MD.

BY

A. V. Abbott

THE year 1892 will always be conspicuous in the annals of American engineering as presenting an extraordinary Street Railway development. In proportion to its size, probably the city of Baltimore would lead the list in improvements in rapid transit facilities, for at the beginning of 1892 only one cable road was in operation in the city, while the end of 1892 will undoubtedly see at least four additional cable roads and five electric roads, aggregating two hundred or more miles of track in full operation. Conspicuously among the electrical equipments the Lake Roland Elevated Railway may be mentioned. The city termini of this road are located at the corner of Charles and Lexington streets and at the corner of Baltimore and North streets. From these points the road runs northerly through North street to North avenue, thence westerly to Oak street, where the line splits into two parts, one running nearly due north by Druid Hill Park, through Roland Park to Lake Roland, and the other running due west to the suburb of Walbrook.

On North street, to avoid conflict with the tracks of the Northern Central Railway, an elevated structure, built similar to the New York elevated railways, has been introduced, by means of which the tracks of the Lake Roland Road are raised sufficiently above the street level to carry them over the tracks of the Northern Central Road and allow free passage of locomotives and freight cars underneath the electric road.

ROADBED AND RAIL STRUCTURE.

Through the paved streets of the city, commencing at Charles and Baltimore streets, and extending as far north as Cold Spring Lane, Duplex street railway track has been used. The rail is supported in cast-iron chairs having bases 12 inches x 14 inches square. These chairs are set at intervals of 5 feet 4 inches. The gauge of the track is 5 feet 4 inches, there being an old-time ordinance in the city of Baltimore which limits all street railway tracks to this gauge. At each chair a tie bar connects the two rails of each track to prevent any possibility of spreading; thus it is obvious that the entire structure embedded in the street is of a metallic character and not liable to cause interruption of street traffic by rotting or disintegration of wooden ties. The bearing areas of the chairs have been carefully calculated so as to present a sufficient area in contact with the soil of the street so that there may be no settlement under carload. In cases where the subsoil of the street is particularly soft, a block of concrete is introduced under the chair to give additional bearing area. Through the city streets the wide tram section has been used to afford a rail which shall present little or no difficulty to street traffic. North of Cold Spring Lane, however, where the traffic of the street is limited to pleasure travel a narrow tram section is substituted for the previously described section. Outside of the paved streets of the city the roadbed has been very carefully graded, and has been provided with a gravel ballast one foot in thickness of cement gravel of such nature that, after consolidation by wear, dust will be almost

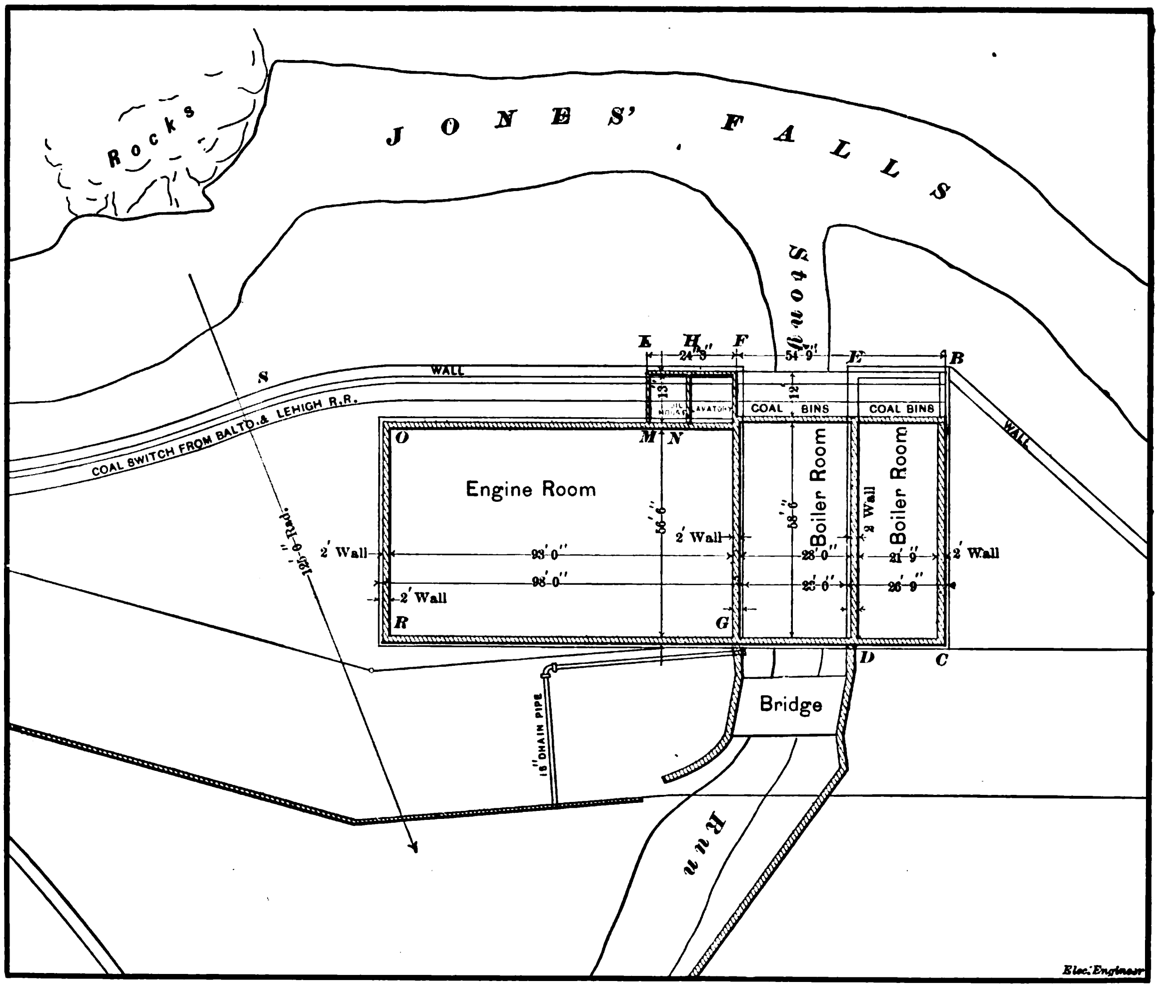

FIG. 1.—POWER PLANT OF THE LAKE ROLAND ELEVATED ELECTRIC RAILWAY.

entirely avoided. At the corner of North street and North avenue the road runs for a distance over the tracks of the Union Line and the Traction Co., and thence proceeds westward to the suburb Walbrook, about three miles into the country. On North avenue the track is composed of 75 lb. Johnson girder rail to a point a little west of Fulton avenue. From this point westward 67 lb. Pennsylvania Company T rail is used, as the streets are unpaved and the necessity for a girder rail is obviated. This part of the road is laid upon vulcanized Georgia pine ties set on 30 inch centres.

The elevated structure commences near Saratoga street, on North street, and extends northward for a distance of nearly 4,000 feet, nearly to Chase street. At each end of the structure the street grade is attained by means of a masonry approach of Gettysburg granite laid on a grade of six per cent. to raise the tracks of the Lake Roland Road to the height of 8 feet above street level. The end of each approach is furnished with a masonry bridge-seat on which rest four lines of Warren girders almost precisely similar in design and type to those of the New York elevated structures and supported on Z bar columns set on piers of Portland concrete. Through the greater part of North street the ground is sufficiently firm so that good foundation for the piers can be obtained with an excavation of about 8 feet. Toward the lower end, however, North street runs through the old bed of Jones's Falls stream where very marshy ground was encountered, necessitating a piled foundation for each of the piers. This piled foundation was accomplished by driving six piles, 8 inches in diameter at the small ends until the piles were firmly embedded in a layer of gravel situated about 18 feet below the street level. The tops of the piles were then cut off to a level grade of 8 feet below the street level and surmounted by a cap-stone 8 feet square and one foot thick, upon the top of which a concrete pier was placed. The tops of these piers are composed of granite cap-stones one foot thick and 24 inches square, carrying four foundation bolts which pass into the concrete and serve to secure the base of the Z bar column. A clear head-room of 20 feet is preserved under all parts of the elevated structure to give ample head-room for all street traffic beneath. The columns for a majority of the spans are 12 inches square; but for two of the long spans the columns are 15 inches square. In order to avoid the railway tracks at the Calvert street station, it has been found essential to introduce two long bridge spans into the elevated structure. These spans are respectively 196 feet and 156 feet centre to centre of end pins. The spans are steel through trusses. The entire elevated structure is built by the Pennsylvania Steel Company from open-hearth and Bessemer steel having an elastic limit of from 32,000 to 40,000 pounds to the square inch, an ultimate strength of from 54,000 to 62,000 pounds, an elongation of not less than 25 per cent. in 8 inches, and a reduction of area of not less than 45 per cent.

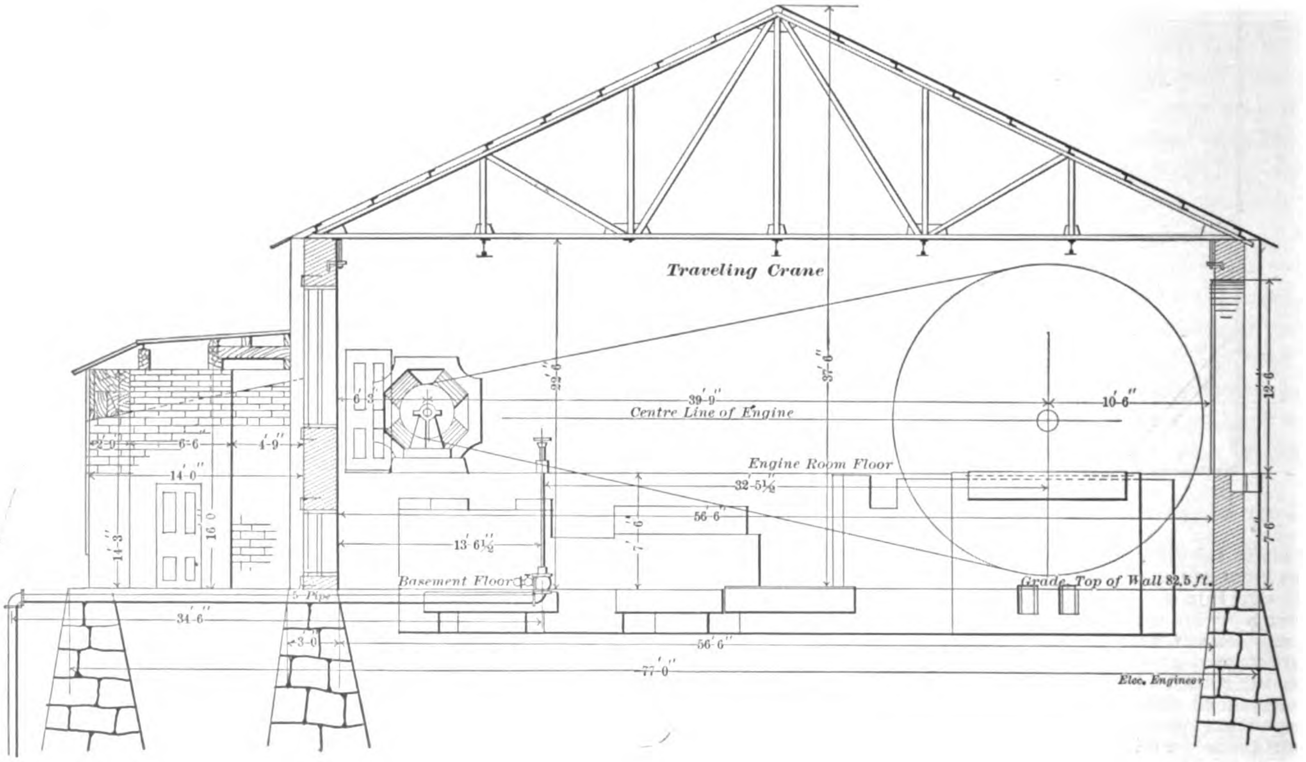

Fig. 2.—Section Through Engine Room.

Another steel structure about 600 feet in length occurs where the road crosses Stony Run stream just north of Hampden avenue, where the grade is about 60 feet above the level of the stream.

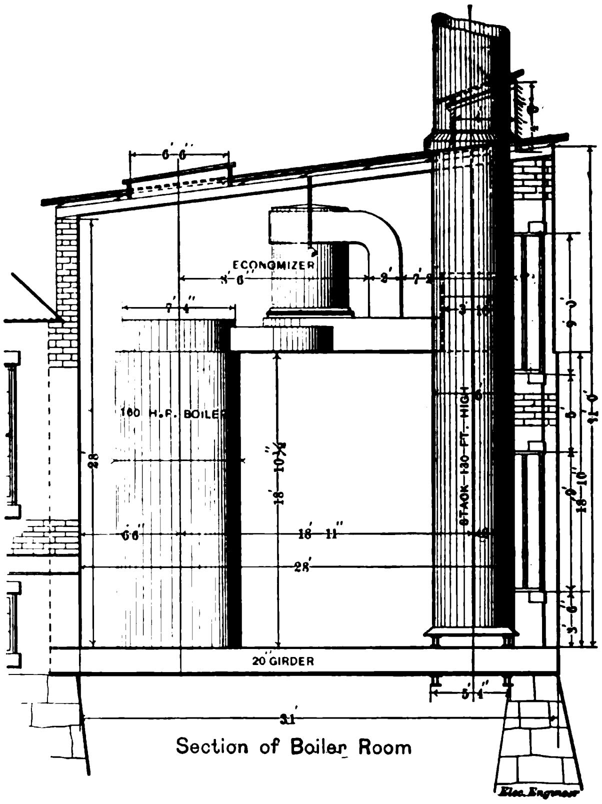

Fig. 3.

This structure consists of eight spans of plate girders alternately 22 feet and 44 feet in length supported on channel iron columns and three spans of Warren girders each 130 feet centre to centre. The deck of the Stony Run viaduct is composed of vulcanized yellow pine ties, as is that of the elevated structure.

THE OVERHEAD LINE.

The railway system is divided into four independent, separate circuits. First, Lexington street circuit; second, North avenuue circuit; third, Cedar avenue circuit; fourth, Lake Roland circuit. The object of this subdivision into separate circuits is to make the different branches of the road as independent as possible from each other. The feed wires for each circuit extend separately and independently from the power station, and, as will be seen from the drawing of the switchboard, Fig. 5, are provided with entirely separate and independent switchboard instruments, so that any circuit may be operated entirely separately from all of the others. At all points of the line where the trolley wires of the different sections come together, circuit breakers are introduced, so that the independence of each circuit is rigidly maintained. All of the trolley wire used is No. 0 hard-drawn copper suspended by Railway Equipment Company insulators. Through the narrow streets of the city span wire construction is used exclusively, the overhead line being supported from heavy iron 6-5-4 inch poles set on either side of the curb stone, the joints being shrunk together and provided with malleable iron splicing pieces. The span wires are all insulated with a breaker at each pole, and are arranged with eye bolts so that the tension of each span may be at any time regulated. The feed wires are carried on the tops of the poles upon wooden pins inserted in special iron pole tops, each pin being insulated by a P P glass insulator to which the feed wire is attached. The wiring of the road is somewhat differently arranged than is frequently customary upon electric roads. The main feeders are nearly all carried to a centre, from which point distributing feeders are run parallel to the trolley wire in both directions. In connection with the overhead line, a rather novel feature of the generators may be mentioned by stating that they are designed to be over-compounded to the extent of about 100 volts. By this means the potential at the terminals of the generator under no load will be adjusted at 500 volts; thus an additional E. M. F. of 100 volts is obtained to counterbalance the fall of potential in the overhead line, and by the arrangement of wiring which has been adopted, the distribution to the trolley wire at any point should not vary over 15 to 20 volts, between no load and full load. This system is now in full operation upon the North avenue circuit and is proving very efficacious. All of the feed wire is of Washburn & Moen manufacture, quadruple grade.

Outside of the narrow city streets centre pole bracket construction is adopted, the poles being 8 inch octagon pine poles. Beyond the end of the double track on North avenue, a double trolley wire is suspended through the entire length of the single track. By this means the use of switches at the turn-outs is avoided.

BUILDINGS.

The buildings for the Lake Roland Elevated Railway will consist of a power station and a car house. The power station is located on the Jones's Falls turnpike road at the intersection of Stony Run with Jones's Falls stream. The car house is located near Wyndhurst avenue in Roland Park. Both of these buildings will be substantial stone structures.

Fig. 1 shows the site selected for the location of the power station. It will be seen that the building is located on the Jones's Falls turnpike at the junction of Stony Run and Jones's Falls stream. This location for the station was selected on account of the cheapness of real estate there to be obtained, the proximity to the tracks of the Northern Central Railway and the Baltimore & Lehigh Railway, enabling coal to be delivered at the station in car loads with no handling, and the unfailing water supply furnished by Stony Run and Jones's Falls, permitting the use of condensing engines and obviating city water bills. From Fig. 1 it will be seen that the ground plan of the building consists of five rooms, a main large room forming the engine-room 93′ by 56′ 6″, a boiler room 28′ by 58′ 6″ and a second boiler-room 21′ 9″ by 58′ 6″; also two small rooms forming a lavatory and oil-house. The larger

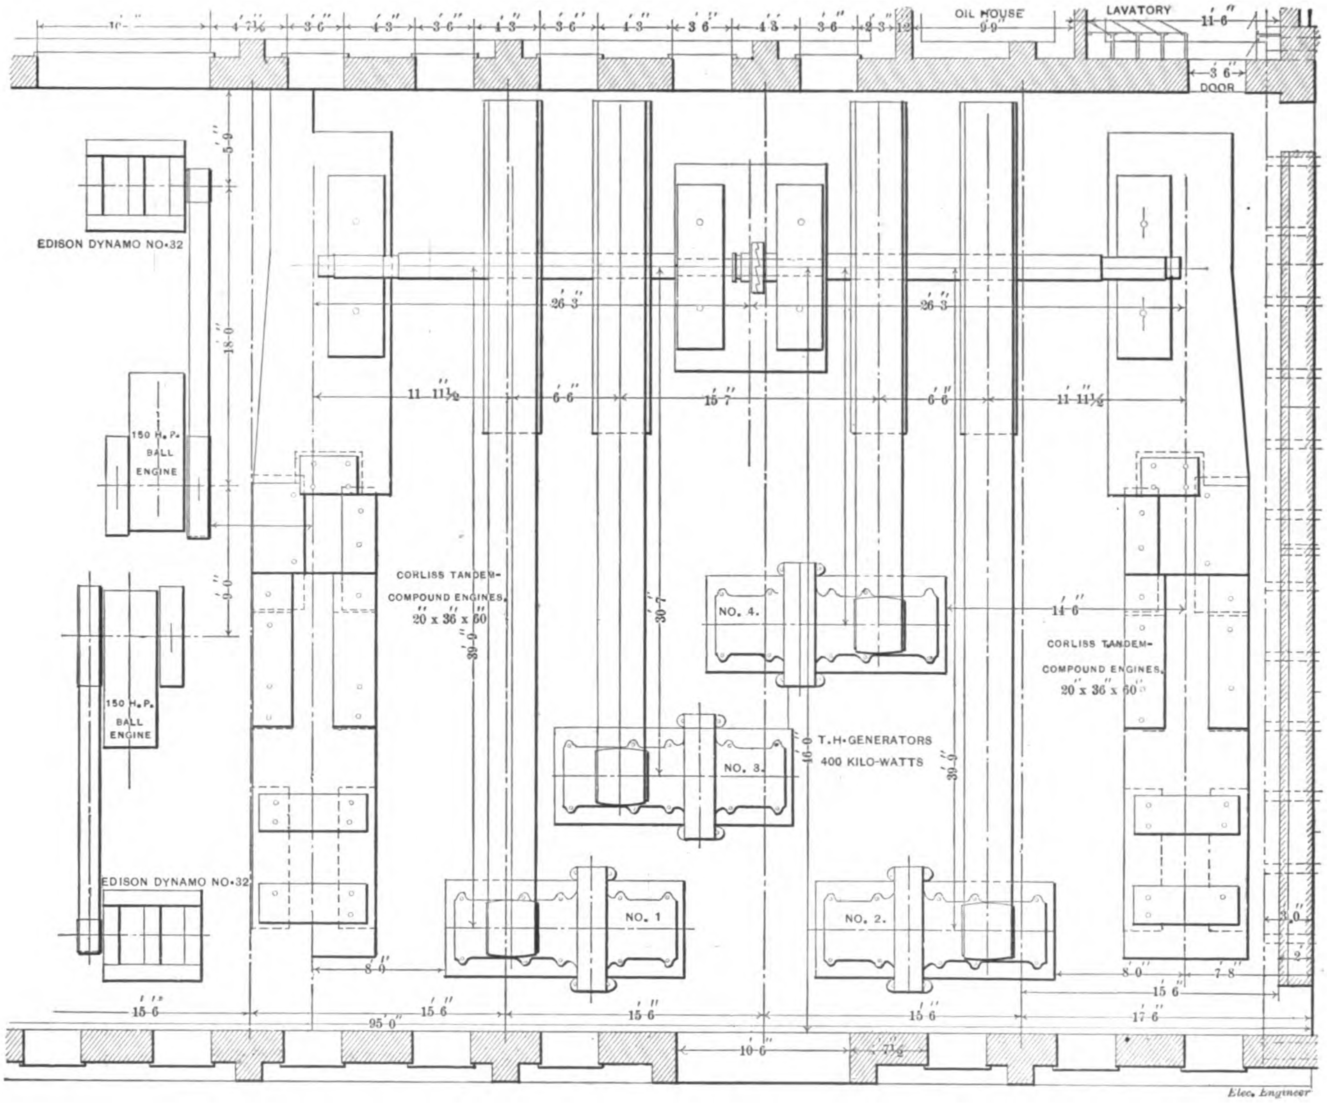

Fig. 4.—Plan of Engine and Dynamo Room, Lake Roland Power House.

of the two boiler-rooms is built directly over Stony Run stream. It will be seen that space is provided for the extension of the engine and boiler-rooms.

The power station is built of what is called Falls Road stone, being a fine grained syenite of very substantial and durable character containing no iron. The walls are 2′ thick with buttresses 12″ by 18″ extending from the ground to the roof level for the purpose of supporting the roof trusses, substantially in accordance with Fig. 2. All the walls are laid up with a mortar composed of Portland cement one part and sand three parts; and by the specifications the stones composing the walls are required to average at least one cubic foot in size.

The engine-room consists of two stories. The basement story is 7′ in height and contains the foundations for the engines and dynamos and all the steam piping of the condensers and feed-water heaters. The main floor of the station is 7½′ above the basement floor, and has access both to the coal track for the reception of machinery and to the Falls road. The main floor of the engine-room is composed of iron eye beams carrying 12″ brick arches covered with 3″ of Portland concrete, the idea being to make the power station absolutely fireproof in every respect.

The roof of the station is built by the Variety Iron Works and consists of iron trusses covered with seam sheet steel. Along the lower chords of the trusses four travelling cranes are provided, one extending over the main shaft, one over the cylinders of the engine and two over the generators. Each of these cranes has a capacity of eight tons, thus providing ample facilities for any repairs. With the exception, therefore, of the window casings and the doors, the station is absolutely fireproof in every respect.

THE STEAM PLANT.

The steam plant, Fig. 4, consists of two tandem compound Corliss engines 20 in., 36 in., 60 in. connected directly together by means of a counter shaft 17 in. in diameter and 52 ft. long. This shaft is divided into two parts, being supported at the centre by two bearings and carrying a jaw clutch so arranged that either half of the shaft can be thrown off at pleasure. On each side of the shaft are two fly-wheels 40 in. face, 20 ft. in diameter, weighing 36,000 lbs. From these fly-wheels belts proceed directly to the pulleys of the Thomson-Houston generators. It is obvious that this arrangement presents one which is at the same time free from complication, and also allows great flexibility in the operation of the station. In case of the disablement of one engine, by opening the connecting rod strap the other engine will be enabled to drive the entire plant; and by opening the clutch at the centre, either engine can operate its two generators entirely independently of the other engine.

The boiler plant consists of six 84 in. vertical Corliss boilers intended to run at 160 lbs. gauge pressure. The boilers are arranged as shown in Fig. 3, in a line along the wall of the boiler-room adjacent to the station. From the tops of the boilers, steam pipes proceed in each direction toward the centre of the engine-room, provided with suitable valves so that either half of the boiler plant may be cut off independently of the other half. Duplicate steam pipes run from the junction down to the basement of the engine-room and thence to the cylinders of the engines, the piping being so arranged that either the high or low pressure cylinder of either engine can be supplied with steam independently of each other. The exhaust piping is also arranged so that the exhaust may be taken from the high pressure cylinder either into the low pressure cylinder through the feed water heater into the condenser or around the condenser into the atmosphere, or around the heater into the condenser, or directly into the air. In the event of accident to the low pressure cylinder, the same arrangements can be made directly from the high pressure cylinder. Thus it will be seen that practically the station is equipped with four independent cylinders, each capable of being operated in any manner separately and distinctly from any one of the other cylinders. In order to attain a maximum steam economy, a large heater is provided for each engine, which takes the overflow from the condenser, and after raising the temperature by means of exhaust steam, forces the feed water through two economizers composed of brass tubes placed in the uptakes from the boilers. By this arrangement the feed water is given a temperature of

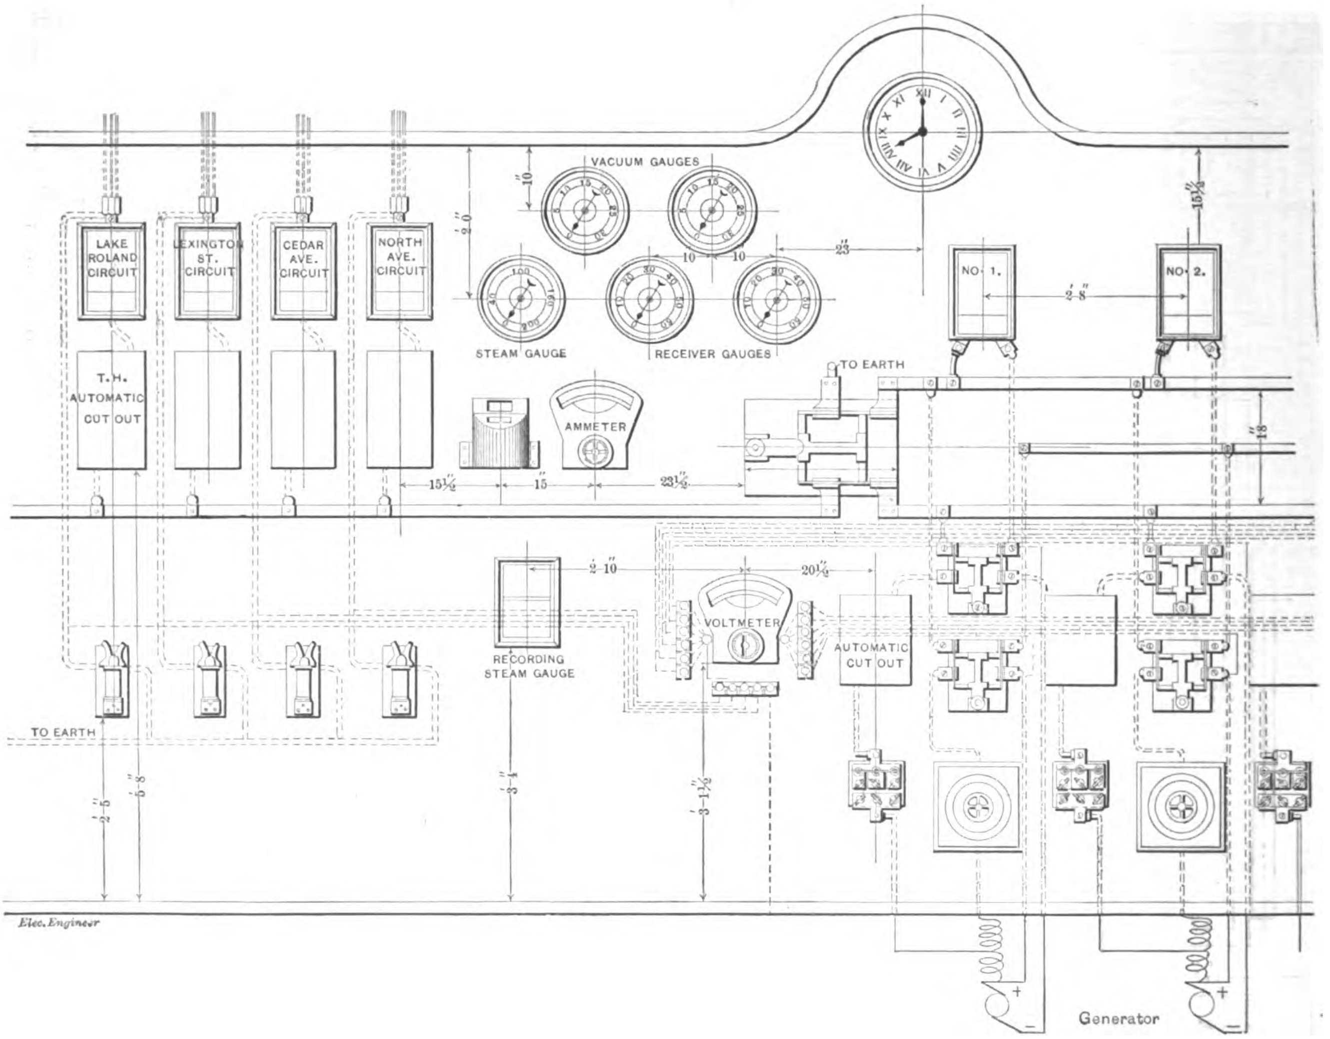

FIG. 5.—ARRANGEMENT OF STATION SWITCH BOARD, LAKE ROLAND ELECTRIC RAILWAY.

about 200° previously to entering the boilers. The feed water is primarily controlled by a directly connected air pump and the condensers to the engines. An auxiliary steam pump and two sets of injectors are also provided so as to obviate any possibility of failure of the feed water supply. All of the feed water, previously to entering the boilers, is passed through a Union water meter provided with thermometers, so that quantity and temperature is constantly measured.

ELECTRICAL EQUIPMENT OF THE STATION.

The electrical equipment of the station consists of four 400 k. w. Thomson-Houston machines of the latest type, especially designed and built for the Lake Roland Road, so as to be over-compounded to the extent of about 100 volts. This over-compounding is controlled by means of a shunt placed around the series coils of each machine, so that the amount of compounding can be varied at pleasure from a plain shunt machine to an over-compounding of 25 per cent. of the generator's normal pressure. These machines are of the four-pole type and show a remarkably small amount of magnetic leakage. In addition, two No. 32 Edison bi-polar generators are placed in the station, being driven by two 150 h. p. condensing Ball engines. It is expected that this small generator plant will be capable of taking care of the service between midnight and six o'clock a. m.

The switchboard, Fig. 5, consists of a large board of polished oak set two feet from the south wall of the station. The board is practically divided into two parts, the left-hand half being arranged for the accommodation of the separate circuits, while the right-hand half is provided for the generators and their apparatus. The four circuits comprising the overhead line of the road are at the top of the board. Here each circuit is provided with its own independent ammeter, automatic cut-out and lightning arrester. From the automatic cut-out the positive bus bar runs toward the right, and is supplied with a main ammeter and a wattmeter and a main double-pole switch. The automatic cut-outs and lightning arresters are of the well-known Thomson-Houston type. The main ammeter and voltmeter are of the new Weston station type, while the wattmeter is a 200 ampere Thomson-Houston instrument, operated in a shunt from the positive bar. The voltmeter is so arranged that it may be connected with the poles of either one of the generators with the generator and the ground, or with either circuit and the ground, at pleasure. By this means a constant supervision may be had over the voltage and insulation of the generators, and the circuits and the conductivity of the latter. On the left-hand side of the board the positive, negative and neutral bus bar are placed, all being of solid copper rod so proportioned that the current does not exceed 1,000 amperes per square inch of copper section. Each of the generators is provided with an ammeter, an automatic cut-out, a triple fuse block, a rheostat for controlling the shunt circuit and two double-pole switches. By following the wiring diagram shown on the switchboard, it will be perceived that the shunt circuit of each of the generaters is not excited by the generator itself, but directly from the bus bars on the switchboard. By this means any tendency to production of unequal voltages in the several machines is entirely avoided; and, consequently, no generator can reverse any other machine and drive it as a motor. The difficulty of running machines in parallel is also largely avoided, it being simply essential in order to get any idle machine into the circuit to get the armature up to speed and close the appropriate switches.

CAR HOUSE.

The car house is a substantial stone building constructed under the same specifications as applied to the power station, and is 204 feet long by 108 feet wide. It is provided with eight tracks, and is capable of accommodating some seventy-five cars. In the southeast corner of the building an office has been provided for the transaction of the company's business, an ample repair shop fully equipped with all tools necessary for street railway repairing, a storeroom, a repair track with four ton traveling cranes and wash track for cleaning cars.

CAR AND MOTOR EQUIPMENT.

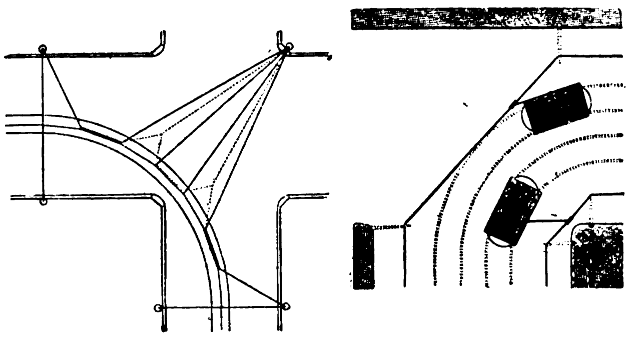
The present car equipment of the road consists of four 16 feet vestibule-end closed cars and three 16 feet open cars. These cars are equipped with four Baxter motors and two Westinghouse motors. The new equipment will consist of twenty-five 33 feet Pullman cars with 33-inch wheels and McGuire trucks. These cars will be equipped with two 30 h. p. single reduction Edison No. 16 motors with series-parallel controlling stands. In the early spring it is the intention to add to this equipment fifteen trail cars to accommodate the excursion travel between Baltimore and Lake Roland.

Eickemeyer-Field Motors.—After an exhaustive test of about six months on the tracks of the Street Railway Company of Steinway, L. I., of the Eickemeyer-Field Mfg. Company's electric railway system, the directors have decided to adopt this system.

THE OVERHEAD CONSTRUCTION OF THE SOUTH STAFFORDSHIRE TRAMWAYS.

In order to simplify the overhead construction of roads having many curves, the management of the South Staffordshire Tramways have adopted a method employing a radial trolley pole and doing away with span wires. The trolley wire is simply suspended upon arms projecting from two to five feet from steel columns about 21 feet above the roadway. The arms are stayed by steel bands. No matter how sharp the curves, no guy wires are employed, the columns being especially designed to withstand severe strains. The whole system depends upon the flexibility of the trolley arm, or, as it is here called, the side collector, which automatically engages the trolley wire in any position from two to twelve feet from the side of the car.

The accompanying diagrams, reproduced from the pages of the London *Electrical Review*, show the radical departure of this system from that in ordinary use. The trolley arm is made of metal, with a ball and socket arrangement, and it revolves on a metal rod placed within in a tube. It is controlled by springs fixed to a loose collar which works on the pedestal of the ball socket. The trolley is hinged to the arm to permit lateral play in any direction and was originally provided with guides. It was found, however, that these were unnecessary, as the trolley guides itself without difficulty.



American and English Trolley Wire Suspension.

ELECTRIC RAILWAY DEVELOPMENT AT TROY, N. Y.

The recent consolidation of the Troy and Lansingburgh Rail Road and the Troy City Rail Road (formerly the Troy & Albia Rail Road) has resulted in the resignation of James O'Neil as president and the election of Chas. Cleminshaw, Esq., to the position. Mr. Cleminshaw formerly held the position in both the Troy City and the Troy & Lansingburgh Roads, but resigned from the Troy City, as he was unable to give proper attention to both roads, and to his immense business interests in addition. The roads now being consolidated, and under one and the same management, the election is considered by his friends as a gratifying endorsement of his ability in managing railway interests in this section. The capital stock of the Troy City Railway Company has been increased from $400,000, to $2,000,000, divided into 20,000 shares of $100 each, and certificate filed with the Secretary of State, endorsed with the approval of the State Rail Road Commissioners. This increase of stock was voted at a recent meeting of the stockholders. The company's debts and liabilities, including the debts and liabilities of the Troy & Lansingburgh Rail Road, which were assumed by the Troy City Rail Road, amount to $739,984. The directors of the company are as follows: James O Neil, William Kemp, Edward Murphy, Jr., Chas. Cleminshaw, Anthony N. Brady, Peter McCarthy, E. Ogden Ross, and Joseph J. Hagan. The increase of stock is desired for the purpose of providing funds for the extension of lines, and also to meet the expense of changing the motive power of the road to the overhead trolley system.

The company has recently placed two new dynamos in the Division street station, and is now amply equipped for all emergencies, using the Lansingburgh station as an auxiliary source of power. The company are placing new cars on the road as fast as required, four having been received from the shops recently. The electric system at the present time is complete with the exception of the branch to Cohoes via Green Island, known as the "White Line," which is still operated by horses. It is stated that the obstacle in the way of equipping this line with electric power is the Delaware and Hudson Rail Road Co. contract, made many years ago, and under which provisions were made for running horse cars over the bridge. The Delaware and Hudson Co., it is stated, consider this contract disadvantageous to its interests, and refuse to renew on the same terms for the electric cars; but it is expected that by next spring a new contract will be drafted.

THE GENERAL ELECTRIC PANEL SWITCHBOARD.

THE General Electric Company in designing the railway power switchboard shown in the accompanying illustrations, had in view a board to which additions could be readily made as the capacity of the plant was increased, and accordingly adopted the panel construction. The panels are 62 inches high by 24 inches wide and are made for four capacities: 200, 400, 600 and 1,000 amperes. They are all exactly similar and a board may therefore be made up of panels of different capacities and yet be perfectly uniform in appearance. It is also possible to change the positions of the individual panels without alteration. They are fastened together by bolts at the back.

On the front of each panel, Fig. 1, may be seen the automatic circuit breaker with a resetting device for use when two or more panels are connected to guard against an undue load being thrown upon one generator. Below this is a Thomson-Houston current indicator lighted by a bracket lamp, and below this, again, is seen the handle of the rheostat. To the right of this is a flash lamp connected in series with five lamps on the rheostat, and on the left is the field circuit switch of the generator. Below are the triple pole main switch, the small double pole switch, connecting the bus-wires for the lighting circuit with the generator leads between the generator and the main switch, and the voltmeter and socket.

The back view of the panel is shown in Fig. 2. The negative bus-bar is at the top, the positive directly below it, and the equalizer bar at the bottom, while between the last two is the rheostat. The magnetic cut-out for the voltmeter circuit and the main circuit lightning arrester are in the lower right hand corner, and that for the lighting circuit in the right hand corner. The connections on the panel are complete and when installing the board it is only necessary to connect the three main leads, the two feed wires from the generators and the necessary ground and line feeder wires.

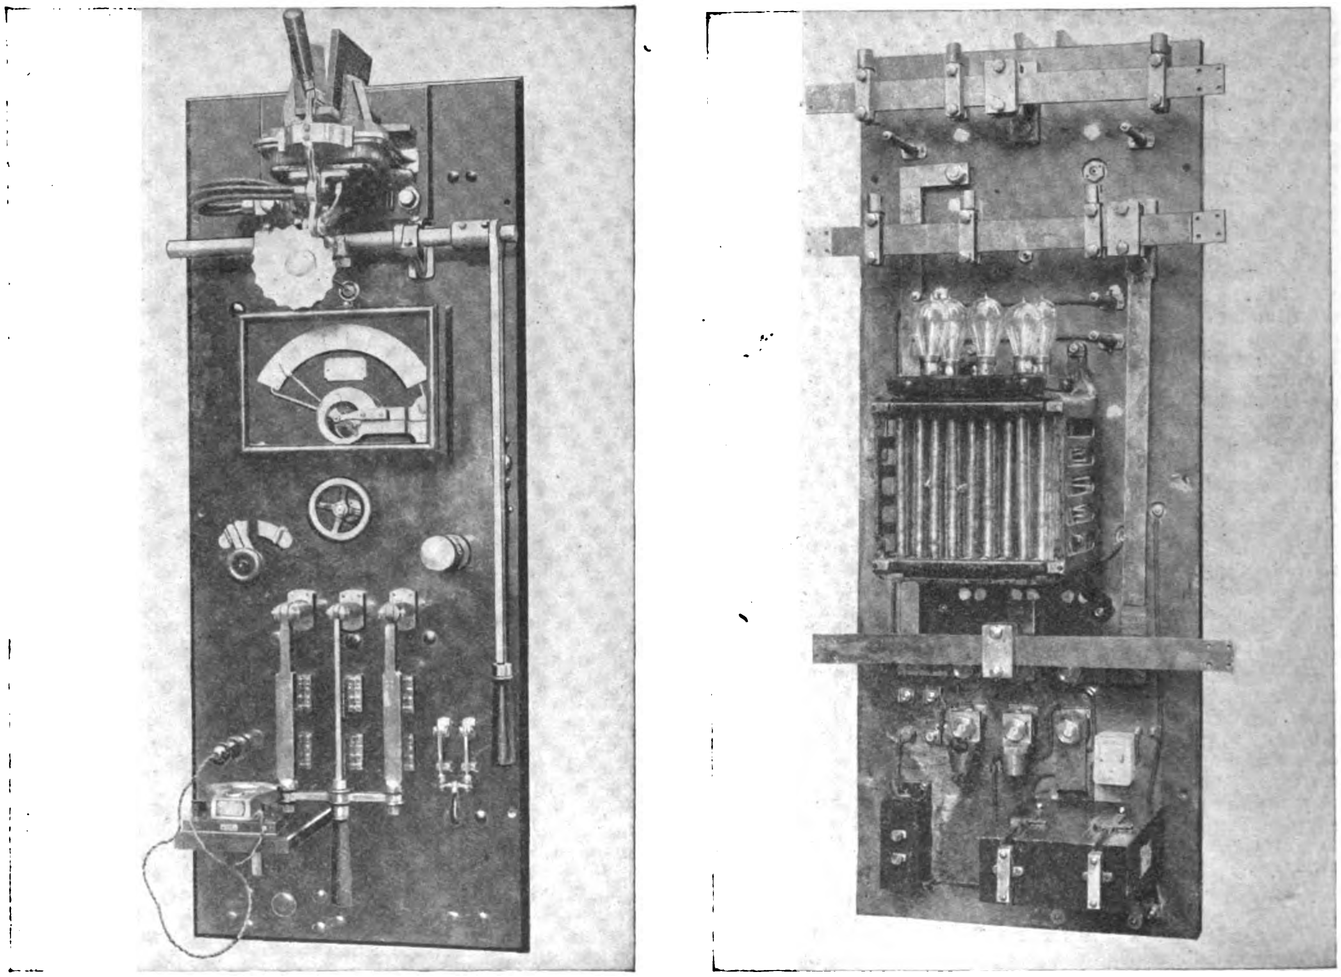


FIG. 1 AND 2.—THE NEW GENERAL ELECTRIC RAILWAY PANEL SWITCH-BOARD.

HIGH-SPEED RAILWAY IN AUSTRIA.

AN interesting lecture was recently delivered in Vienna, at the society of Austrian engineers and architects, by M. Hugo Kostler. The subject was the proposed electric railway for rapid communication between Vienna and Budapest. According to this project, an electric railway would run on the right bank of the Danube at the high speed of 120 miles an hour, thus reducing the journey between the two capitals from five hours to one hour and a half. The distance between Vienna and Paris, which is now covered in 26 hours, would then only require seven hours, and that between Paris and Constantinople would only take 15 hours instead of 65. The trains would have a single car containing 40 passengers, and could be dispatched at intervals of 10 minutes. The differences of grade being taken into account, an electric motor of 200 h. p. would be necessary for each car. It is stated that arrangements are being made to test this system between two important centres.

THE DEMAND FOR ELECTRIC STREET CARS.

IT is predicted by Gen. Horace Porter, vice-president of the Pullman Car Co., and others, that 1893 is to be an active year for electric car building. He says: "A highly important factor in creating the present boom is the fact of so many street car companies, all over the country changing their motive power from horses to electricity or cable, but I believe very largely to electricity. It is surprising the extent to which this change is being made, as indicated by the orders for new cars. Of course such a change necessitates re-equipping the road with cars, and you will readily see that this means a vast amount of car building and rebuilding."

"It is really remarkable," said the agent of one prominent company, "the extent to which electricity seems to be coming into use as a street car motive power. It was predicted that this year would be the biggest yet known in electric car building. It has proved so, but the indications are that next year's output will largely exceed it. We have had to build another plant, almost doubling the size of our works, exclusively for building cars for electric street railroads. And I know this has been the case with several companies. Not only is electricity coming largely into use on old roads, but the growth of street car systems in towns and short railroads connecting towns and villages, has increased at a surprising rate since electricity began to take its place as a practical means of railroad traction, and there is, of course, a corresponding increase in the car building business. Electricity seems to be increasing traveling facilities and conveniences at a greater ratio even than it is superseding old methods of traction."

PERSONAL.

HARVEY L. LUFKIN.

MR. H. L. LUFKIN, who has just become associated with the Crocker-Wheeler Electric Motor Company as Manager, has had a long connection with electrical work, and with more than one branch of the industry. Some early experiments of his in the then new field of long distance telephony covered all the New England territory in 1883-4 and were afterwards carried as far as Cleveland, Ohio, using the Gray Postal steel core, copper plated wire. In 1885 Mr. Lufkin went to Central America to push some government concessions in which he was interested, and while at Trujillo he found a set of Bell instruments, sent out to the authorities, who had been unable to set them up for want of knowledge. Mr. Lufkin at once put up a circuit—the first in the Republic of Honduras—which worked so well that in order to avoid becoming president of the Republic by acclamation, at the next revolution, Mr. Lufkin returned to this country, leaving a great many disappointed admirers behind him.

Arriving in New York in 1886, Mr. Lufkin, who had meantime kept himself informed of the advances in electrical work, became interested in the C. & C. Electric Motor Company, soon after its original incorporation, and nearly all its early motors were installed by him or under his supervision. The exhibition made by him of C. & C. motors at the Philadelphia meeting of the N. E. L. A. in February, 1887, was the first of its kind, and did great good in many ways, while the growth since that time of the exhibition feature of these conventions has become matter of history. Before the same Association at New York, in August, 1888, Mr. Lufkin read a most valuable and interesting paper on "A Basis from which to calculate charges for Electric Motor Service." This was of a theoretical nature and was followed up by a practical paper read at the Cape May meeting in August, 1890. Both papers are standard reading to this day.

In the field of factory power transmission, Mr. Lufkin is a pioneer. The first complete electrical power plant on record was the fine one installed in the C. & C. factory, and beyond that are many others, of later date, including the Fraser & Chalmers at Chicago, which is the largest of its kind, and was also laid out by Mr. Lufkin. Several important mining installations are also due to his energy and ability, among them being the Belmont Consolidated; the Sheridan & Mendota; and the Helena & Livingston, all of them most interesting examples of electric power work. In the development of this line of engineering, Mr. Lufkin has made a close personal study of the mining conditions of the West, and he is therefore remarkably well informed on this new and difficult branch of the subject.

Mr. Lufkin is not yet in the prime of life, but with so much experience and so high a reputation, he may safely be counted upon to distinguish himself in his new relationship and to confer further benefits upon the growing electrical power industry which has already seen so much of his intelligent work.

WILLIAM S. HINE.

MR. WILLIAM S. HINE, formerly General District Agent, of the Westinghouse Electric and Mfg. Company in this city, has assumed the general sales-management of the J. T. Case Engine Company, of New Britain, Conn. The Case engine, which many of our readers will know of as an oscillating engine, has already attracted considerable attention from the novelty of its construction and its peculiar adaptability to small electric stations and isolated plants. The company is to be congratulated on having secured the services of Mr. Hine in pushing its introduction especially into the field of electric lighting, in which he has had so wide an experience.

MR. FRED. DELAND, who for some years past has been the Western manager for the W. J. Johnston Company, Ltd., and the representative of *The Electrical World*, has resigned his position and will hereafter have no connection whatever with the concern. Mr. DeLand, who is a graceful writer, will become the World's Fair correspondent of the *Scientific American*. His long years of faithful service have won him many friends in technical and industrial circles, and he will now have an excellent opportunity to do good work and derive some benefit from it. Mr. DeLand will also conduct a monthly paper called *World's Fair Electrical Engineering*.

LETTERS TO THE EDITOR.

THE LIGHT THAT SHOULD NOT BE ON TROLLEY LINES.

THERE is a matter of importance that I desire to call attention to and which has not received the consideration deserved. It is in regard to arc lighting on electric railways. There is a company that advertises in the various electrical journals an arc light, stating that it can be used 10 in series on 500 volt circuits. I consider their lamp a good one, but this is not the light I refer to, but to the one in series on top of the car—the arc between a defective trolley wheel and the wire.

Why railway companies continue to illuminate their routes in this manner, I cannot conceive when the first-named system would be preferable by reason of its economy, better distribution of light, and the safety of the public in general. I have noticed numbers of times melted metal drop from the trolley to the top of car and the ground below.

If trolley poles were properly attended to when out of adjustment, and if eccentric or defective trolley wheels were removed when necessary and trued up or new ones substituted, it would make the poor overworked motor beneath the car—I have heard its groans and shrieks of agony—put on the seraphic smile supposed to be worn only by angels when having their photographs taken for a Sunday-school picture.

X. I. M.

ANOTHER "ELECTRICAL FIRE" NAILED.

IT was reported by the morning papers of November 30th, that a fire had been caused by electricity at the *Mail and Express* building, 203 Broadway, where the offices of THE ELECTRICAL ENGINEER are located.

As per your request I made an inspection of the premises in company with the underwriters' expert, and no evidence was found that could attribute the cause of the fire as coming from the electric light wires. The true cause of the fire was from what is known as a gas pocket under the floor; said pocket being an accumulation of gas which had escaped from an imperfect joint at the base of the fixture.

The underwriters' expert ascertained that there had been for some time a general complaint throughout the building in regard to escaping gas, and all the evidence which was obtained from the people in charge showed conclusively that the fire was caused by this pocket of gas igniting at the base of the fixture, and setting fire to the floor above.

I trust that this report will be of some assistance to you, and hope that your valuable journal will deny specifically that the fire was caused from faulty electric lighting.

INSURANCE EXPERT.

NEW YORK CITY, DEC. 1, 1892.

DO LINES OF FORCE ROTATE WITH AN IRON CORE?

PLEASE allow me to ask a question concerning a statement which Mr. Edward C. Boynton, Jr., M. E., makes in his paper "On Unipolar Dynamo Construction," published in your esteemed journal of Nov. 16, 1892. The statement is as follows:

"If the core of a bar magnet be rotated about its longitudinal axis, no matter whether the energizing coil be rotated with it or not, the lines of force are practically stationary and do not rotate with the core."

The question I wish to ask is this: Can the author describe some experiments, his own or somebody's else, which prove directly the correctness of his statement? I do not remember having seen anywhere a direct experimental proof of that statement and therefore conclude that the proof, if it exists at all, is not known quite as well as it deserves to be.

M. I. PUPIN.

NEW YORK, NOV. 22, 1892.

"A PLEASURABLE TASK."

ON Wednesday THE ELECTRICAL ENGINEER, of this city, gave a house warming which was largely attended by engineers, journalists and business men, who were glad to offer their congratulations upon the prosperity of the paper and the comfort and convenience with which it is housed. Last April this journal moved into its present quarters in the *Mail and Express* building, 203 Broadway, New York, where its offices now occupy the entire eighth story of the Fulton street wing, covering a floor space of 2,060 square feet. Messrs. Phelps, Colvin, Martin and Wetzler on this occasion had an opportunity to show what adepts they were in dispensing hospitality and it is needless to say they proved themselves equal to the pleasurable task. An elaborate luncheon was served.—*Western Electrician.*

MISCELLANEOUS.

THE USE OF COMPOUND WOUND GENERATORS FROM A PRACTICAL POINT OF VIEW.[1]

BY M. WILLIS.

In all electric installations, whether for incandescent lighting or power transmission, the first requirement is that the dynamo or dynamos shall maintain a constant potential difference at the brushes or at some distant point. On examination we find that the shunt machine by armature reaction alone as a single factor, not to mention the host of other factors,'is unable, in practice or theory, to fill the before-mentioned requirement, viz., to keep a constant potential difference at any point predetermined without hand regulation or some form of governing device, such as an automatic rheostat, for instance. The requirements are the most nearly reached by the compound machine, the E. M. F. of which keeps constant or increases directly as the load on the machine increases.

We find in the building of compound machines that certain conditions are assumed. In the first place we find that the speed of the machine is assumed constant. This of course introduces a slight source of error, as in practice, in a large percentage of cases, more especially small plants, the speed varies at least 2 per cent. This does not take into consideration the creepage of dynamo belts, which amounts to from 1¼ to 2½ per cent. by actual experiment, not to mention belt slippage. All these factors of course increase in direct proportion to the load. In railway practice and in the transmission of power a few per cent. variation is, however, permissible. It would seem advisable to over-compound even railway generators to a slight extent to make up for small variations of speed. This may be accomplished in some machines without special winding, as, for instance, by carrying the length of a German silver shunt used to shunt a portion of the main current past the series coils and thus allow a larger proportion of main current to flow through the series coils of the machine.

We will now consider the use of the compound and over-compound machines under various conditions. Taking the case of a compound wound machine running singly, we find that its series winding may be constructed with such a number of turns that it will practically compensate automatically from no load to full load; for all internal reactions, such a machine is evidently eminently fitted for railway and similar work, as it will maintain a practically constant potential at the generating station.

The next case is one in which we have an over-compounded generator, running singly, and we find that its series coils, if correctly constructed, will fairly compensate for internal reactions and also for the varying percentage of loss in line, all of which will vary directly with the current. A machine of this class and under these circumstances would be admirably fitted for incandescent lighting and transmission of power, and more highly fitted for railroad work than a straight compound machine.

The next case is one in which we have two compound wound machines running on the three wire-system. Their series windings will compensate for internal reactions and thus keep the potential at generating station constant, even if the system becomes unbalanced, as the excess load on one side above another would pass through the series coils of the more heavily loaded machine and increase its magnetic field, thus keeping its potential at a level with the more lightly loaded machine. Under similar conditions, of course, a shunt machine would lower its potential.

The next case is one in which we have two over-compounded machines running on the three-wire system, and one finds that, however unbalanced the load may be, both machines will maintain a practically constant potential at any predetermined point if the compounding is correctly figured; 110 volt dynamos of such a type and under such circumstances would be the correct thing for incandescent lighting where the distance of lamps from the generating station does not exceed one-half mile, where the cost of conductors on the 110 volt system and the cost of transformers on the alternating system would make these systems too expensive in comparison with the 220 volt system.

Another case is one in which we have compound wound generators running in multiple on the two-wire multiple arc system. We find that the generators will compensate for internal reactions but will not compensate for loss in transmission. Machines of this form and running in multiple would be but little better than straight shunt machines. One of the only advantages is that they would divide the total load among them more equally than shunt machines would under similar conditions.

Finally we have a case in which we have over-compounded generators running in multiple. The series winding will fairly compensate in the average manufacturer's machine for internal reactions due to varying load and also when all machines are running for all variations in loss in the system due to varying load. It is this form and arrangement of generators for incandescent lighting which is at present rightly popular for isolated plants.

The author then assumed a case in which an arrangement of over-compounded machines in multiple will not maintain a constant potential at the lamps, namely, when two or more compound machines are run in multiple, and all are cut out but one. In doing this it would be found that the voltage at the lamps would increase considerably, for the reason that when at full load, with all machines running, the loss is 10 per cent. in feeders and the voltage of lamps correct. When we cut out all machines but one, say, then the total current which was previously divided among all machines will be drawn from the remaining one, and, in consequence, will pass through its series coils and thus raise the voltage at the lamps, because the percentage of loss in feeders has varied from 10 per cent. to the percentage of loss at, say, one-third load. This case may prove very serious with 110 volt lamps. On two-wire multiple arc systems, for instance, the voltage at lamps would vary from 110 volts to at least 118 volts. Of course, in this case hand regulation with ordinary generators would have to be resorted to, and the only benefit derived from the compound winding would be the accurate division of load between compound wound generators running in multiple and the practically automatic regulation obtained for varying loads with all machines running.

A solution of the problem of how to keep voltage at lamps down when all machines but one, say, are cut out, would be to either wind the series coils in sections and, when machines are thrown out, to short circuit a certain portion of each of the series coils of the rest of the generators, or to operate a shunt of variable resistance, which shunt would cut down current flowing through the series coils in direct proportion to the number of machines cut out. In addition to this it would also be advisable to excite the shunt field spools of all machines from a separate exciter, run from an independent source of power from that which runs the generators themselves.

One finds in practice that few compound machines will maintain within one per cent. constant potential at any predetermined point, as a factor will creep in which it is almost impossible to provide for in the compound winding, and that is the heating up of the machine, which depends on the ventilation of the machine itself, on the ventilation of the dynamo room, and also on the temperature of the outside air. It might be said that in general too much is expected of a compound or over-compounded machine and too few allowances are made.

THE MAGNETIC FIELD.[1]

BY PROF. E. J. HOUSTON.

PROF. HOUSTON opened his remarks by the definition of the magnetic field, and described the curious properties possessed by that field, which he summarized under three heads. The lecturer next referred to the lodestone, pointing out how this ore and its magnetic powers were known to the ancient Chinese, Greeks and Romans. He gave quotations from various authorities, giving the name in several languages, given to the lodestone. Prof. Houston then spoke of the directive power of the magnet, and drew attention to the fact that the Chinese were aware of it and steered vessels by it about 2,000 years before Christ; while a magnetic needle in the shape of a mariner's compass was known to the Syrians about 1242. The lecturer mentioned the writings of Robert Boyle about the year 1668, then spoke of the widespread though erroneous impression that the north end of a magnetized needle pointed to the exact north pole of the earth; there was always a varying deviation to the east or west of the true geographical north, except at very long intervals of time. A dipping needle was exhibited, showing that a magnetized body was not only attracted in a horizontal but in a vertical plane.

Prof. Houston then referred to Faraday as the father of the modern science of electricity, and held that one of his greatest merits was to deny the possibility of magnetic action through space independent of some medium; this led to the theory of the magnetic field, and the conception of lines of force through surrounding space, leaving the magnet at one end and returning at the other.

He showed the field of a magnet by using both iron filings and nails, and followed that by lantern slides showing the fields formed by horseshoe magnets, the opposing poles and the attracting poles of magnets. A very good method of photographing the lines of force was then shown, the process being that already described and illustrated in THE ELECTRICAL ENGINEER.

It was shown that bodies suspended in the field of a magnet became in time magnets of themselves. Experiments were made to demonstrate this. A resemblance was drawn between electric and magnetic flow, as to source of energy, conductors and receptive devices. Prof. Houston spoke of Oersted's discoveries, and discussed the theories of Hughes and Ewing. In closing,

---

[1] Abstract of a paper read before the Chicago Electric Club, November 21, 1892.

[1] Abstract of a lecture delivered before the N. Y. Electrical Society, at Columbia College, Dec. 1, 1892.

Prof. Houston showed how the earth was a huge magnet, the lines of force coming from the south where the north magnetic pole is agreed to lie, passing through the air surrounding the earth and re-entering the south magnetic pole in the northern hemisphere. It follows that magnetic needles in this field will have the lines of force threading through them because of the permeability of the body, thus directing the pointing of the needle according to the direction of the earth's lines. Prof. Houston spoke in high terms of Mr. Nikola Tesla and his work, and concluded with the belief that the time would come when photographs could actually be taken of the lines of magnetic force.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED NOVEMBER 22, 1892.

Alarm and Signals :—

Electric Signaling Device, J. J. Ross, Detroit, Mich., 486,569. Filed Dec. 29, 1891.

A signaling apparatus automatically operated by a moving train.

System of Railway Signaling, T. A. Edison, Menlo Park, N. J., and E. T. Gilliland, Boston, 486,634. Filed April 7, 1885.

Relates to apparatus for electric signaling between a fixed station and a moving train by induction.

Pneumatic Fire Alarm, A. A. Lehmann, Baltimore, Md., 486,675. Filed Feb. 1, 1892.

Employs a pneumatic device for closing a normally open electric alarm circuit.

Successive Non-Interference Signal Box, W. E. Decrow, Boston, Mass., 486,702. Filed July 25, 1890.

Consists of devices by means of which, if one or more boxes are released while others in the same circuit are liberated, there will be no confusion, and the liberated boxes will transmit their signals successively.

Electrical Hose Signaling Apparatus, W. Fowler, Colorado Springs, Col., 486,807. Filed Feb. 8, 1892.

Electrical Annunciator, F. S. Carter, Burlington, N. J., 486,820. Filed June 4, 1892.

Employs a dial having pointers pivotally attached thereto and intercepting-pins collectively moved by an electro-magnet.

Dynamos and Motors :—

Dynamo-Electric Machine, G. Baehr, Brooklyn, N. Y., 486,524. Filed Dec. 18, 1891.

Employs a field magnet so constructed as to prevent the stoppage of the machine in case some of the coils should be destroyed, and an armature and commutator so constructed as to bring the two as close together as possible, and make the machine compact, and also provides a simple way of supporting the armature upon the shaft.

Lamps and Appurtenances :—

Incandescent Electric Lamp, G. A. Frei, Springfield, Mass., 486,457. Filed March 14, 1892.

Claim: In an incandescent electric lamp, leading in or circuit wires, an incandescent filament, a joint for uniting said filament and said circuit wires, consisting of a single tube, one end of which receives an end of the filament and is thereto secured, and the opposite end thereof receives an end of the leading in wires and is fused thereto.

Carbon-Brush Holder for Dynamo Electric Machines and Motors, J. J. Wood, Ft. Wayne, Ind., 486,656. Filed May 3, 1892.

Electric Arc Lamp, W. C. Meissner, Chicago, Ill., 486,488. Filed April 15, 1892.

Employs a shaft having two pinions which engage the carbon rod racks, two oppositely faced ratchet-wheels, two dogs on the ends of the pinion cross-bar, and means for running such cross-bar so that the racks are engaged and move in either direction.

Suspension Device for Incandescent Lamps, S. Porter, Boston, Mass., 486,604. Filed Nov. 23, 1891.

Electric Lamp Shade, C. J. Miller, Philadelphia, Pa., 486,729. Filed April 21, 1892.

Electric Arc Lamp, J. Brockie, London, Eng., 486.757. Filed Aug. 6, 1891.

Employs two solenoids, one having a coil of coarse wire in the lamp circuit, and an integral core linked to one arm of the lever, the other having a coil of fine wire in shunt to the lamp circuit and a divided core, part of which is linked to the opposite arm of said lever, the latter being linked to the carbon feeding device.

Measurement :—

Electrical Measuring Instrument, E. Weston, Newark, N. J., 486,689. Filed June 4, 1891.

Employs two magnets relatively arranged to produce an annular field of force, a conductor in loop form rotating in said field, and a spring opposing the movement of said conductor.

Metal Working :—

Electrical Method of an Apparatus for Forming Tubes, G. D. Burton, Boston, and E. E. Angell, Somerville, Mass., 486,624. Filed Sept. 16, 1891.

Relates to a method and mechanism for heating and coiling bars into tubes by electricity.

Electric Metal Heating Apparatus, G. D. Burton, Boston, Mass., 486,625. Filed Oct. 21, 1891.

Relates to mechanism for electrically heating metals preparatory to forging.

Electric Forging Apparatus, G. D. Burton, Boston, and E. E. Angell, Somerville, Mass., 486,626. Filed Jan. 13, 1892.

Has for its object to provide an automatic feed for the bar to be heated, heating the moving section to a forging temperature and shaping it to the desired form ; all the operations being accomplished electrically.

Electric Forge, G. D. Burton, Boston, and E. E. Angell, Somerville, Mass., 486,627. Filed Jan. 13, 1892.

Employs a converter provided with exterior rings constituting opposite poles, conducting brackets attached to the rings, arms connected with the brackets, and clamps having laterally extending jaws carried by the arms for the purpose of heating sheets of metal for forging.

Electrical Metal Working Apparatus, G. D. Burton, Boston, Mass., 486,816. Filed Oct. 26, 1891.

Employs a converter provided with two exterior rings of opposite polarity having conducting arms attached upon which are mounted electrodes provided with contact rolls.

Miscellaneous:—

Lightning Arrester, H. G. Osburn, Chicago, Ill., 486,498. Filed Dec. 26, 1891.

Employs a generator receiver providing a normally closed path connected to the circuit, and having a ground connection and adapted to produce a current of sufficient E. M. F. to counteract the current in the charged circuit.

Process of Electrically Reducing Refractory Compounds, T. L. Willson Leaksville, N. C., 486,575. Filed April 20, 1892.

Process consists in first impregnating a pulverized metallic compound with a reducing agent by saturating it therewith while the latter is in a liquid condition, and then subjecting the whole to the heating action of an electric current.

Apparatus for Recording Speech or Other Sounds, W. Bruening, East Orange, N. J., 486,603. Filed July 23, 1891.

Electric Releasing Device, W. R. Hewitt, San Francisco, Cal., 486,612. Filed Aug. 23, 1892.

An electro-magnetic releasing device for hitched animals.

Current Director, J. F. McElroy, Albany, N. Y., 486,643. Filed Jan. 2, 1892.

Employs a divided circuit, a revolving armature, a fixed portion with which the armature coincides, and fixed coils in the branches of the circuit which embrace the extremities of the armature during the coinciding interval.

Current Regulator, J. F. McElroy, Albany, N. Y., 486,644. Filed March 21, 1892.

The terminals of the field coils are secured to fixed contacts and connected in circuit by a movable segmental contact plate, so that by adjusting this plate on its pivot, by means of two pawl and ratchet devices automatically actuated, the number of active field coils may be varied.

Electric Device for Vibrating Tables, W. L. Imlay, Camden, N. J., 486,715. Filed April 9, 1892.

Electric Clock, M. V. B. Ethridge, Everett, Mass, 486,838. Filed Jan. 18, 1892.

Electric Heater Casing, M. W. Dewey, Syracuse, N. Y. Design, 22,017. Filed Oct. 19, 1892.

Railways and Appliances :—

Insulating Chair for Rails, F. E. Kinsman, Plainfield, N. J., 486,477. Filed Feb. 23, 1892.

Claim 4 follows:

The combination with a railway rail and its support of an interposed sheet or plate of insulating material and a plate of iron or other metal clamped down upon the insulation so as not to move with the rail.

Trolley Wire Hanger, D. E. Lain, Yonkers, N. Y., 486,588. Filed April 11, 1891.

Employs grooved jaws partly embracing the wire, and means for clamping these jaws by moving them endwise on the wire.

Telephones and Apparatus :—

Electric Switchboard, C. E. Scribner, Chicago, Ill., 486,506. Filed Feb. 7, 1890.

Invention relates to the construction of a telephone switchboard and the loop plugs used in connection therewith.

Test System for Multiple Switchboards, C. E. Scribner, Chicago, Ill., 486,507. Filed Feb. 11, 1892.

Has for its object to provide means whereby it may be certainly determined at any board whether a line is in use at some other board; said means being distinct and separate from the line circuits.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED NOVEMBER 29, 1892.

Alarms and Signals :—

Burglar Alarm Cabinet, A. Stromberg, Chicago, Ill., 486,908. Filed July 9, 1892.

Auxiliary Fire Alarm Signal Apparatus, C. E. Scribner, Chicago. Filed June 1, 1888.

Provides an auxiliary circuit including generator and bell at one or more stations so arranged that when the generator is operated its bell will be rung until the brake wheel of the signal box begins to turn, whereupon the ringing will cease.

Burglar Alarm, H. W. Reynolds, Long Branch, N. J., 487,128. Filed April 6, 1892.

Distribution :—

Development and Distribution of Electricity, J. S. Stone, Boston, 487,102. Filed Oct. 10, 1891.

Employs a conductive circuit and inductive circuit, and a single bridge connection forming a conductive section common to both of said circuits, a generator in the conductive circuit, a transmitting device in the inductive circuit, and a current varying device in the bridge connection.

Lamps and Appurtenances :—

Electric Arc Lamp, C. E. Scribner, Chicago, Ill., 486,938. Filed Jan. 2, 1888.

Invention consists of a lifting magnet in the main circuit, a fine wire magnet, in shunt around the arc, and a shunt around both these magnets including resistance and contact points controlled by either of said magnets to open or close the shunt circuit including the resistance.

Adjustable Electric Light Holder, L. S. Pfouts, Canton, O., 487,022. Filed Feb. 24, 1892.

Electric Light Carbon, J. Clegg, London, England, 487,046. Filed April 10, 1890.

Invention consists in treating the filaments with certain metallic compounds with the object of making them more durable and efficient.

Incandescent Lamp, J. H. F. Görges, Berlin, Germany, 487,049. Filed April 20, 1892.

Claim 1 follows:

An incandescent lamp provided with three terminals connected with each other through three independent carbon filaments of equal resistance.

Automatic Electric Lighting Apparatus, L. G. Woolley, Grand Rapids, Mich., 487,109. Filed June 6, 1892.

An automatic electric lighting apparatus so arranged that by the operation of a single lever the inlet valve to a motor is open and a dynamo thrown into operation by the tightening of its operating belt.

Incandescent Lamp Socket, C. B. Elliott, Boston, 487,213. Filed August 8, 1892.

Consists of a rigid base having the lamp contacts molded permanently therein in a given plane and coupling contacts rigidly held in a plane at right angles thereto.

Electrode for Arc Lamps, C. W. Hazeltine, St. Louis, Mo., 487,220, Filed May 6, 1892.

Has for its object to effect a saving of carbon by coating the electrode with a covering of copper and another of zinc.

(See page 544.)

Measurement :—

Electric Current Indicator, C. P. L. Noxon, Syracuse, N. Y., 487,093. Filed Nov. 24, 1891.

Has for its object to provide apparatus for determining the strength of any kind of current by employing the direct application of the current to be measured in actuating the indicating of the apparatus.

Metal Working :—

Magnetic Separator, T. J. Lovett, Chicago, Ill., 487,073. Filed Feb. 13, 1892.

Magnetic Separator, T. J. Lovett, Chicago, Ill., 487,074. Filed Feb. 13, 1892.

Miscellaneous:

Machine for Covering Wires, J. A. Barrett, Brooklyn, N. Y., 486,845. Filed May 10, 1892.

Magnetic Separator, T. J. Lovett, Chicago, Ill., 486,879. Filed Feb. 13, 1892.

Galvanic Body Battery, J. W. Shults, Wichita, Kans., 486,902. Filed March 22, 1892.

Electrical Transformer, E. Thomson, Swampscott, Mass., 486,916. Filed May 23, 1892.

Claim 1 follows:

A transformer for electric circuits provided with means for varying the length of one of its windings in a continuous unbroken manner.

Coil for Electrical Apparatus, H. C. Buck, Somerville, Mass., 486,926. Filed Dec. 5, 1884.

Invention consists in a coil composed of a series of convolutions being surrounded by a coating of paraffine or other plastic insulator.

Electro Magnetic Pulley, W. E. Harrington, Atlantic City, N. J., 487,070. Filed June 2, 1891.

A pulley having a rim of conducting material made magnetic by suitable windings, a hub of conducting material, a wheel centre of non-conducting material, and a connection from the hub to the windings of the rim.

Electric Belt, J. H. Johnson, Dodgevillen, Wis., 457,185. Filed July 21, 1892.

Process of Electro-Depositing Alloys, S. Q. Cowper-Coles, London, 487,176. Filed Nov. 18, 1891.

Railways and Appliances:—

Trolley for Conduit Railways, B. Olbricht, Brooklyn, N. Y., 486,985. Filed May 17, 1892.

Invention consists of a conduit having metallic conductors attached to the under side of the top one on each side of the slot, and a hinged spring actuating trolley arm with two contacts each provided with a swinging casing to prevent short circuiting in the case of water rising to the level of the trolley.

Device for Transmitting Motion for Electric Street Car Motors, W. E. Harrington, Atlantic City, N. J., 487,069. Filed Oct. 4, 1890.

Claim 1 follows: The combination with two pulleys made powerfully magnetic by suitable winding of an endless belt of magnetic material running over said pulleys and held thereto by magnetic traction.

Electric Locomotive, C. M. Conradson, Madison, Wis., 487,124. Filed Dec. 2, 1891.

Employs a system of gearing that may be used when required for extra power and thrown off connection when the circumstances do not require their use.

Switches and Cut-Outs:—

Electric Switch, W. J. Schultz, Detroit, Mich., 486,987. Filed June 27, 1892.

Relates to means whereby the switch lever may be thrown in opposite directions by the action of the same spring.

Safety Device for Electric Circuits, G. Cutter, Chicago, Ill., 487,002. Filed Feb. 19, 1892.

Has for its object to provide convenient means whereby fuses of the right size may be substituted for those that are blown out.

Electric Switch, J. J. Nate, Chicago, Ill., 487,092. Filed Mar. 29, 1892.

Relates to switches and rheostats for use in connection with elevators, and provides means for closing the circuit through the field of the motor before that of the armature.

Telegraphs:—

Electrical Transmitting Appartus, A. D. Neal, Boston, and H. F. Eaton, Cambridge, Mass., 486,888. Filed April 17, 1891.

Has for its object to provide an apparatus whereby letters or other characters may be transmitted over a single line wire as rapidly as the keys can be manipulated

Typewriting and Printing Instrument, A. D. Neal, Boston, and H. F. Eaton, Quincy, Mass., 486,889. Filed June 9, 1891.

An electric printing telegraph on the principle of the typewriting machine.

Telegraphic Apparatus, J. A. Parker, St. Louis, and L. L. Summers, Chicago, Ill., 487,154. Filed Jan. 27, 1891.

Invention has particular reference to the use of machines both as transmitters and receivers, having devices approximating the Bartholomew stenograph shorthand machine.

Electrical Typewriter, A. D. Neal, Boston, and H. F. Eaton, Quincy, Mass., 487,227. Filed May 27, 1892.

A type telegraph system employing typewriting machines of any ordinary construction as receivers and transmitters.

Telephones and Apparatus:—

Automatic Telephone or other Electrical Exchange, A. B. Strowger, Chicago, Ill., 486,909. Filed Feb. 19, 1892.

Invention relates to means for switching any electrical instrument into electrical connection with any other electrical instrument of a given system, and provides means whereby a person at one station may make connection with any other station without the assistance of an operator at a central station.

Multiple Switchboard System, C. E. Scribner, Chicago, Ill., 487,096. Filed Mar. 5, 1892.

Employs a connecting plug consisting of a central conducting core and a concentric conducting sleeve insulated from the core and allowing a part of the core to extend beyond its end, and insulating pit secured to said core.

Telephone Exchange System, C. E. Scribner, Chicago, Ill., 487,097. Filed Apr. 16, 1892.

Provides means whereby sub-stations may be divided into several groups each with a separate switchboard and each member of each group being enabled to obtain connection at one or the other of the switchboards with another member of the same or of another group respectively.

Telephone Switchboard Apparatus, C. E. Scribner, Chicago, Ill., 487,098. Filed Apr. 21, 1892,

Provides means for automatically disconnecting the operator's telephone set from a telephone line circuit.

Telephone, C. V Hayes, Cambridge, and W. L. Richards, Malden, Mass., 487,219. Filed Sept. 10, 1892.

A magneto telephone for two circuits comprising a double pole magnet and helices for each circuit, the poles and helices of each magnet being arranged in a position inductively neutral to those of the other.

Electric Typewriter, A. D. Neal, Boston, and H. F. Eaton, Quincy, Mass., 487,228. Filed May 27, 1892.

A type telegraph employing an automatic field mechanism for the ink ribbons of the transmitting and receiving typewriters.

Printing Telegraph, A. D. Neal, Boston, and H. F. Eaton, Quincy, Mass., 487,229. Filed Apr. 21, 1891.

Employs a typewriter which may be used for ordinary office work use as well as a transmitting instrument, each character being under the control of a magnet actuated by means of the key lever.

MR. S. G. NEILER has severed his connection with the Thomson-Houston Electric Company, of Boston, where he had charge of central station construction in New England for the past two years, and is now connected with the World's Columbian Exposition in Chicago, as second assistant electrical engineer under Mr. Frederick Sargent.

OBITUARY.

JAY GOULD.

THE death of Mr. Jay Gould, last week, at the early age of 57, has been the theme of numberless newspaper articles; and the endless columns of biography, gossip, criticism and conjecture as to the size of his fortune leave little to be said that can be of any value to the electrical engineer. Mr. Gould's connection with electricity was wholly through his telegraph and cable interests; in fact, it has been generally understood that of the later developments of electricity he had little knowledge. It has even been said, more than once, that he did not like the electric light and did not entertain a very high opinion of electric traction. This simply shows that Mr. Gould was not a pioneer, that he had not found time of late years to look far beyond the limits of his existing "investments," and that probably he would not have become interested in telegraphs had it not been for his strong personal friendship for General T. T. Eckert. The story of the Atlantic & Pacific and American Telegraph oppositions is old and hackneyed, but the fact that Mr. Gould died the possessor of between $20,000,000 and $30,000,000 of Western Union stock is proof that Genl. Eckert enabled his staunch ally to reap by them the fruit of an unparalleled opportunity. Mr. Gould was a director of the Western Union Co. for twelve years, and his term of control witnessed the acquisition of the Mutual Union and Baltimore & Ohio properties. Mr. Gould is reported to have left about $75,000,000, largely in railroads, as might have been expected. He was essentially a railroad speculator and his first relation to telegraphy was for him a fortunate accident.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

The judicious placing of advertisements is an important part of any progressive business.

THE SPERRY RAILWAY MOTOR AT PITTSBURGH.

A GREAT deal of interest has been taken in the Sperry motor since its exhibition at the Cleveland Street Railway Convention, and it has now been installed on various roads. The following is an expert report of a test of its capabilities on the road of the Suburban Rapid Transit Company at Pittsburgh, Pa.:

"We made the 1¼ miles up the grade in eight minutes one trip, and ten minutes the next, with three stops. It runs very smoothly. This is the new line just opened by the Suburban Rapid Transit Company and is the one which connects with the Birmingham Traction Company's lines at Carson street, going up the hill and connecting with the original suburban line out in the country. The detail of the particular grade spoken of is as follows: Ten per cent. grade for 300 feet, then a railroad crossing; 6.3 grade for 5,850 feet beyond that point; the remaining 300 feet varying from 1 to 3 per cent. grade; there being in this 6.3 grade eight curves of rather small radius. The more I use the motor, the better I like it; it is a dandy."

THE COLEMAN STORAGE BATTERY.

A LARGE share of the attention of electrical workers has recently been turned towards improving the storage battery. Mr. Clyde Coleman, of the Electric Specialty Co., 85 Fifth avenue, Chicago, has been an earnest worker for some time past in this direction, and as the result of his labors has invented a new form of storage battery which is formed directly by a special electrolysis process, no applied oxides of any kind being employed. With this cell he is able to obtain six ampere hours capacity per pound of cell without shortening the life of the battery or deteriorating it in any way. The new cell, it is said, differs from all other cells of this class, as the active portion of the plates is formed of a peculiar fibrous texture capable of withstanding the highest discharge or even absolute short-circuits without any injury, buckling or other troubles incident to severe working of a battery. Another feature is that if the plates are taken from the cell and left to dry, the active material does not become brittle or crumble. These cells seem likely to become very popular. Attention is called to the announcement made in our advertising columns regarding them.

A MUNICIPAL PLANT FOR LANSING, MICH.

MR. J. P. THOMAN, superintendent of the Board of Water-Works and Electric Light Commissioners, of Lansing, Mich., writes us: "As an item of news I would say that our city has this day, December 1, taken possession of the electric lighting plant of our city company. It will hereafter be run in connection with the water-works and under the same board and superintendent."

THE WIRT ELECTRIC INDICATORS.

These instruments are designed to meet the severe condition of the most exacting commercial practice in electric lighting. The intention of the designer has been to produce an electrical measuring instrument without the faults of temporary or permanent variation, mechanical defects or imperfect design so often found in instruments of this class and which, to quote Mr. Swinburne, "Measure nothing in particular." Whether the object has been fully or even partly accomplished the following description will perhaps enable the reader to judge.

Fig. 1 is a view of the inside of a volt indicator, and Fig. 2 that of an ampere indicator. The cases are similar to high grade steam gauge cases and have cast iron boxes with heavy ornamental polished bronze rims. These rims are cast and have the "draw-file" finish so much admired, instead of being spun and buffed according to the usual practice with work of this class. The glass front is finished in black and pure gold leaf. The case is moisture proof, dust proof and "time proof," which is a very important matter and often not appreciated. Fig. 3 is a detached view of the armature system.

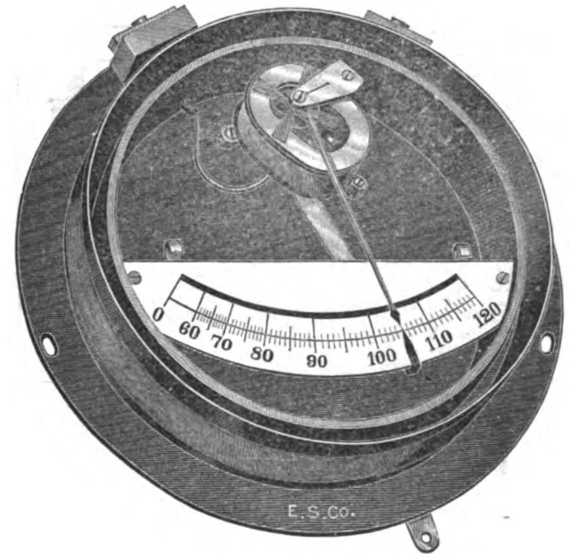

Fig. 1.—Wirt Volt Indicator.

The resistance wire used in the volt indicators is one of the new alloys which have appeared in the past few years. The one selected has not the highest resistance nor the least temperature variation of those tested for the purpose. It is superior to 18 per cent. German silver in both qualities and remarkably constant as regards slight change from year to year, which is the most important feature by far in this case.

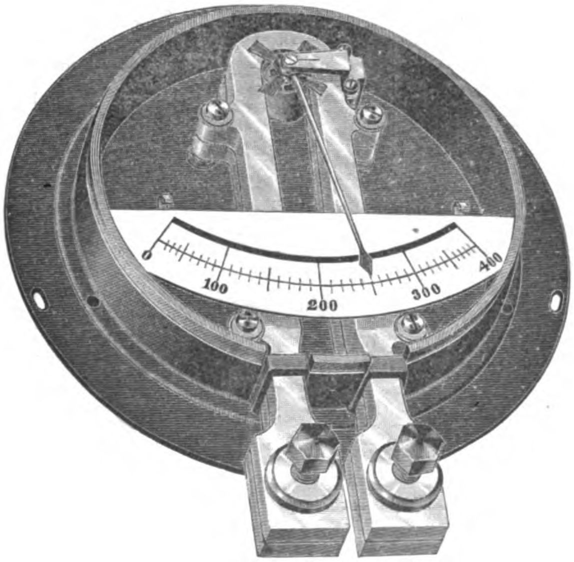

Fig. 2.—Wirt Ampere Indicator.

It is manifestly impossible to simplify an action consisting merely of a stationary coil acting on a light piece of iron free to move in response to the attraction exerted.

In such an instrument the moving parts are reduced to one, control is left to gravity; the varying strength of the field due to the coil is known to be rigidly proportional to the current in the same, and it is only required that the iron which acts as the straw in the magnetic "wind" shall be so selected, shaped, treated and acted upon, as to eliminate "magnetic memory."

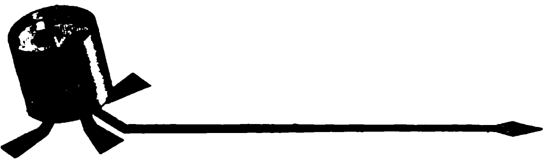

Fig. 3.—Armature System of Wirt Indicators.

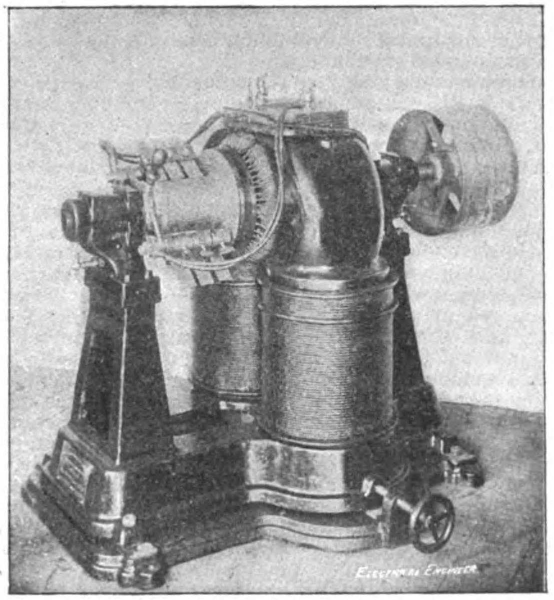
Fig. 1 shows the interior of the 120-volt indicator. The action consists of an oblong spool having ends with a cylindrical curve. The armature is a semi-cylinder of thin sheet iron suitably attached to a light steel spindle with conical ends carried in jeweled cups of special shape designed to give the maximum sensitiveness. The attached pointer is made of thin bronze ribbon having the stiffness of tempered steel and formed to a V section. Aluminum was tried for these pointers at first, but it was found that weight for weight, other materials were stiffer and more satisfactory.

Fig. 2 shows the interior of a 400 ampere indicator, the conductor consisting of a single turn. For large size ampere indicators, the "coil" or strap is cast of pure copper. These instruments are being put upon the market by the Electrical Supply Co. of Chicago.

LIGHTING THE WINTER CIRCUS, PHILADELPHIA.

A new amusement place has been built and opened in Philadelphia. It is certainly a most novel entertainment, and the only one of its kind in America. It is called the "Winter Circus" and is a combination permanent circus, ballet and variety performance. One of the most prominent and handsome features in the entire installation is the electric lighting system which has been installed by the La Roche Electric Works, of Philadelphia. The lighting is done in four colors. white, green, red and blue.



La Roche Dynamo for Winter Circus, Philadelphia.

In the dome of the building there is an electrolier 47 feet in diameter whereon are 300 colored lights neatly arranged. There are two galleries and on them are also placed colored lights. The entire wing is so grouped on an automatic switchboard that the entire house can be changed instantly to the various colors. In the dome is arranged a water-fall. The water falling on the circular stage, under the effect of the different colored lights, is very beautiful. The effect of the colored lights on the ballet is also very fine.

There is placed in the dynamo room a Southwark engine, one 400-light La Roche incandescent, compound wound dynamo, and two 20-light arc dynamos. There are altogether 750 incandescent lights and 53 arc lights. The La Roche Electric Works should be complimented upon the beautiful effect of the entire installation, and on their new automatic dynamo here shown, as there is only a variation of 1¼ volts from no load to full load. The machine is well built and runs with the utmost smoothness.

THE MODERN BOILER PLANT OF CURTIS DAVIS & COMPANY, CAMBRIDGEPORT, MASS.

Electrical engineers will be interested in the description of a strictly modern boiler plant, which has been designed and constructed for Curtis Davis & Company, manufacturers of soap and glycerine, Cambridgeport, Mass., by Westinghouse, Church, Kerr & Company, of Boston; the detail work being carried out by William R. Roney, the engineer of their stoker department. Carte blanche was given the engineers to design a boiler house to contain every practical element of economy which could bear upon the sum total of the cost of making steam; they being limited only to the horizontal return-tubular type of boiler by certain considerations outside of economy.

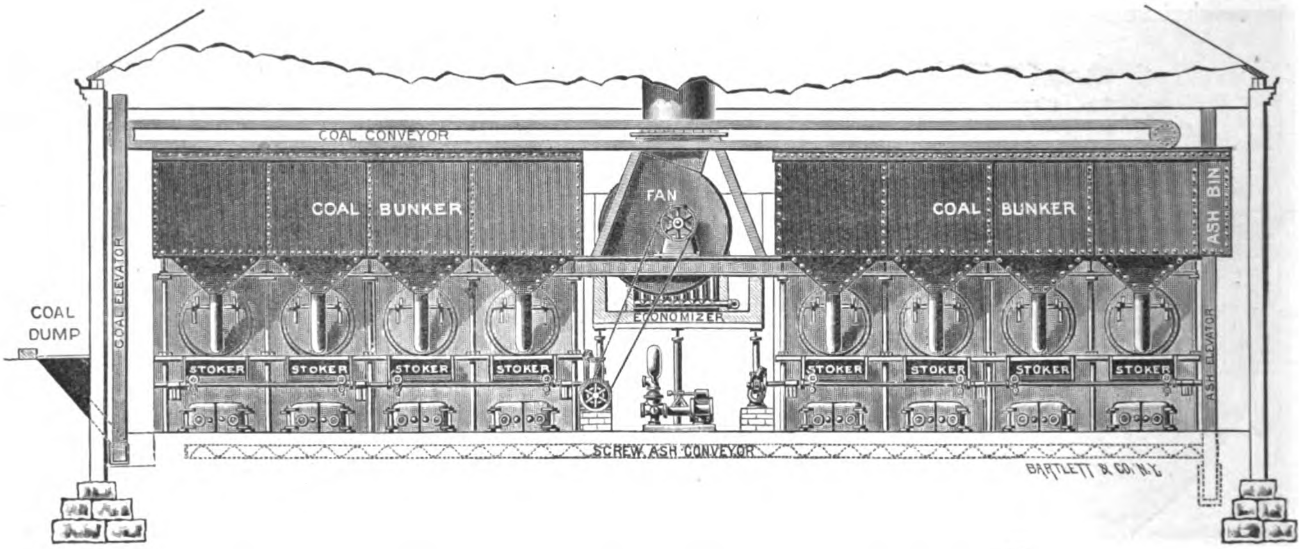


Fig. 1.—Boiler Plant of Curtis Davis & Company, Cambridgeport, Mass.

The architectural design of the boiler house was prepared by Hartwell & Richardson, of Boston. The building is of pressed brick with trimmings of pink Milford granite. The roof is of iron trusses, covered with slate and lined on the inside with wire lath and plaster, for the purpose of preventing condensation. The fire room floor is of concrete. An annex to the building contains a scale room for tallying the weight of coal, and a complete wash room for the fireman, who has now become a gentleman of leisure.

The operative portion of the plant will, when completed, consist of eight horizontal return-tubular boilers of 125 nominal h. p. each, to carry a working pressure of 130 pounds. These boilers are arranged in two batteries of four each in either end of the building (one battery is now in operation), the space between being utilized as a pump room. Following the progress of the coal, after it is weighed, it is dumped onto a grating at the end of the boiler house, shown in the view Fig. 1. The large lumps are easily broken by the teamster, the grating serving as a screen to reduce the coal to a uniform maximum size. From the grating the coal falls into a bucket elevator carrying it to an overhead conveyer extending the entire length of the boiler house, shown in Fig. 1, from which it distributes into square iron bunkers having hopper bottoms. From the bunkers the coal flows by gravity through swivel spouts to the hoppers of the stokers as shown in Fig. 2.

Each boiler is equipped with a Roney mechanical stoker. The power to operate the entire battery of stokers is a small engine carried on a bracket at one end of each battery, and driving a slow-moving eccentric shaft.

A most interesting portion of the plant is the means of securing controllable draft. The usual expensive chimney stack is conspicuous by its absence, and in its place will be found a steel stack 72 inches in diameter, extending 17 feet above the ridge of the roof and showing a total height to the top of about 55 feet above the ground. This stack is lined with one course of brick merely to prevent rust, and is finished with ornamental top similar to the familiar shape on the smoke stacks of the Pennsylvania Railroad locomotives. The stack having no functions, so far as the production of draft is concerned, is only of a length sufficient to deliver the gases above the roof. The stack is supported on an entablature, which in turn is carried on "I" beams over the boiler room. On these "I" beams is a large slow-running exhaust fan whose outlet discharges directly up into the bottom of the stack, as shown in Fig. 1. The waste gases from the furnace pass through a Lowcock economizer, which opens into the suction of the fan. The economizer is carried on iron columns, and the whole system is therefore overhead and out of the way, leaving a clear floor space below. A by-pass damper is provided on each side of the economizer, so that the draft can be direct to the stack in case the economizer is temporarily out of service for repairs. A steam-cone nozzle may be set in the base of the stack as a relay in the remote contingency of any necessity for overhauling the fan. The probability of repairs is best judged by the fact that the usual speed of the fan in ordinary service is from forty to fifty turns per minute, and when driven at the slow speed of eighty turns per minute it is sufficient to cause a draft adequate to the most intense combustion. The motive power of the fan is a small Westinghouse engine, nominally of 10 h. p., but in fact running at so slow a speed and under such a close throttle as to develop only a fraction of that power. The draft is automatically controlled by a pressure regulator in the steam pipe to the engine, so that the speed of the fan is varied according to the steam pressure in the boilers, being in this respect the equivalent of the most sensitive steam damper. This scheme of mechanical draft is capable of producing a draft pressure equal to that of a 200 foot chimney costing ten times as much to build, and additionally possesses the feature which no natural draft enjoys, of absolute flexibility in meeting sudden demands of steam.

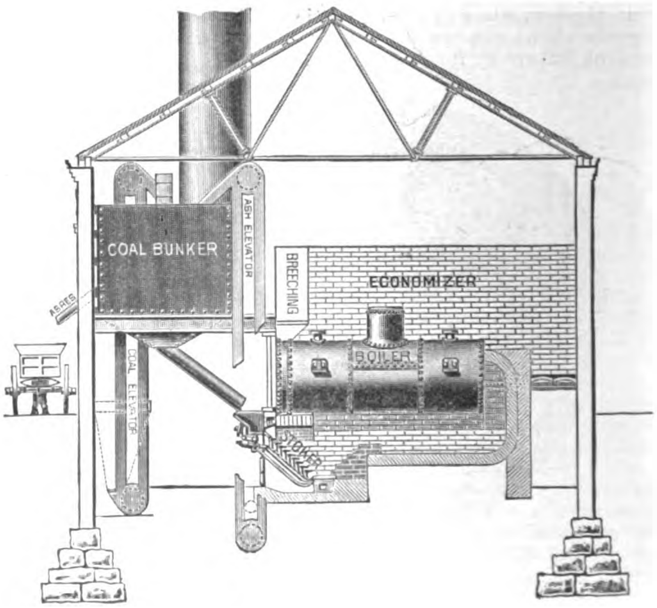

Fig. 2.—Cross Section of Boiler Plant.

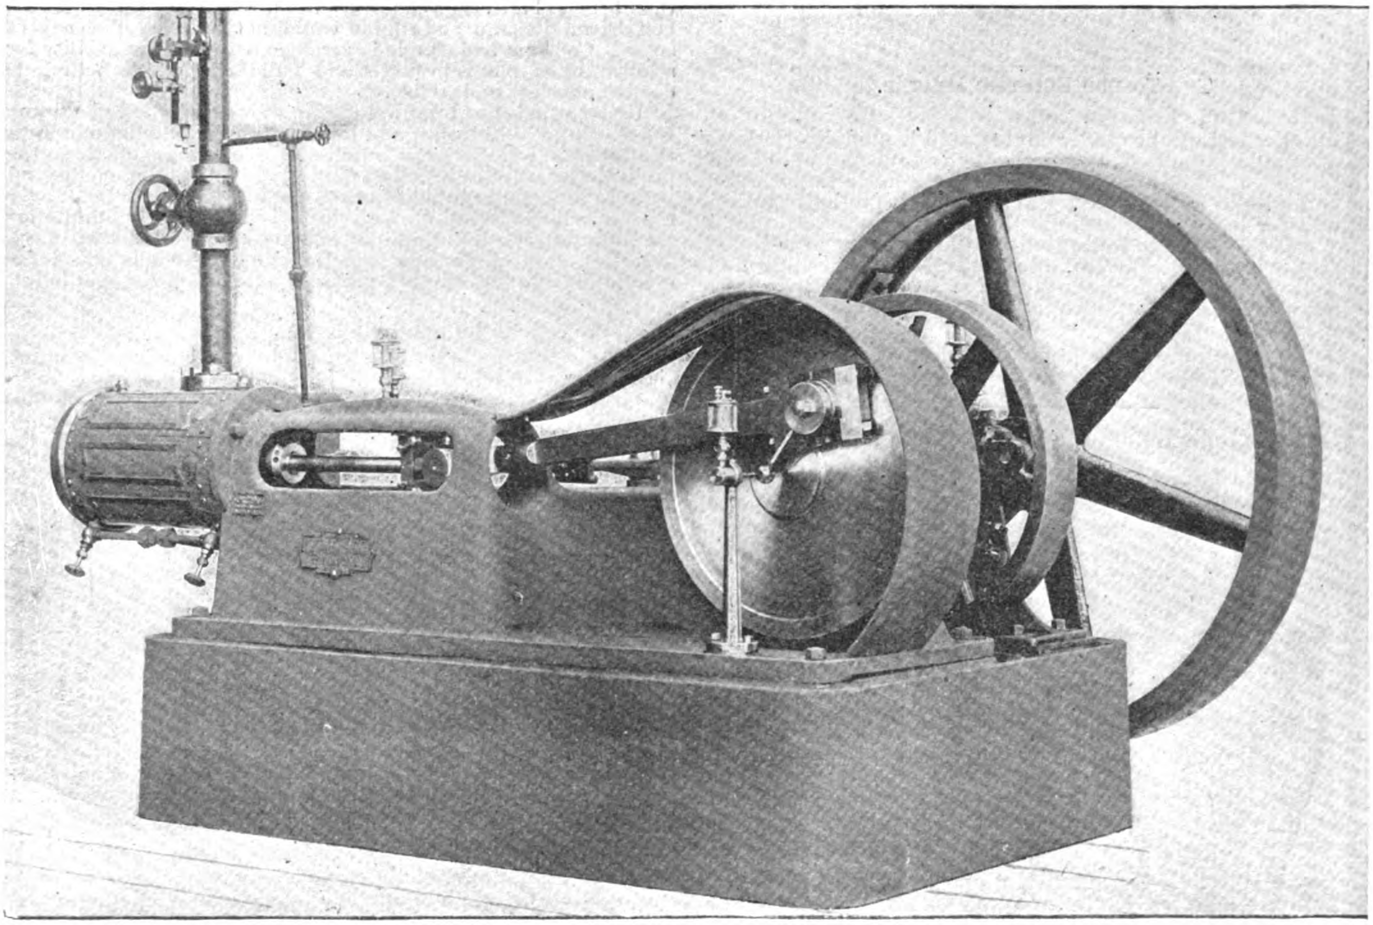
The action of the economizer is, to extract all the available heat from the waste gases and return them into the boiler. The temperature of the uptake is about 100°, the temperature of the feed-water leaving the economizer being upward of 300°, and representing an amount of heat saved which would otherwise be wasted up the stack as the only means of producing a natural draft. The pump-room is located, as before mentioned, between the batteries of boilers underneath the economizer, and in it are two duplex pumps of a capacity of 500 gallons per minute each. These pumps are controlled by pressure regulators, and are so connected that while one of them is furnishing the ordinary elevator service the second one is kept slowly moving, so as to be in condition for instantaneous fire service. The work of these pumps is alternated daily, and in case of fire both can be concentrated immediately on the fire lines. In the same pump-room are double boiler feed-pumps, each one adequate to the entire capacity of the plant. All the hot-water lines and fittings are of brass, and by-passes are provided so that the feed-water can be pumped through the economizer, or direct to the boilers in case of repairs to the latter. A further system of a water meter with by-pass valves is so arranged that the feed-water can be measured and pumped to either boiler independently, or to any number of boilers, or to the entire battery, at will. With a water meter in the feed line and a pair of scales at the gate, it is proposed that the condition of the entire plant, as to its evaporative duty, shall be daily logged and reported to the office, and any decline of efficiency be thereby promptly and practically detected.

NOYE ELECTRIC LIGHT ENGINES FOR STEAMBOATS.

When contracting for electric light plants for the fine new steamers of the Menominee Transit Company, Cleveland, Chief Engineer Calder required, as a preliminary condition, that special engine designs be submitted. It is frequently necessary, in boat work, to provide the engine with an iron sub-base of strength and weight—one that will make the engine absolutely self-contained. Moreover the governor must be especially easy of access, both for taking up and for lubrication, and be of such design and construction as to regulate within the least possible percentage while remaining insensible to the motion of the boat.



Noye Electric Light Engine for Steamboat Work.

To meet these conditions the John T. Noye Manufacturing Company, of Buffalo, N. Y., submitted designs of the engine, which we illustrate herewith, and these Mr. Calder accepted. Six engines were accordingly furnished, and as proof of their having completely "filled the bill" it can be said that they have needed no repairs or extra attention during the season, and are now, at its close, in perfect condition, although much of the time they have run with a steam pressure of 150 pounds instead of the 100 allowed for by the builders.

These engines are of six-inch bore, 10-inch stroke, and run at 300 revolutions. The top of the fly-wheel turns toward the cylinder, but can be made to run the other way if desired. The governor is an adaptation of that used on the Noye heavy-duty B style engine, and ensures perfect regulation. Every engine is carefully tested and adjusted, and can be shipped complete without affecting the adjustments. Other particulars may be obtained of the John T. Noye Manufacturing Co., Buffalo, N. Y.

THE J. G. BRILL COMPANY.

The J. G. Brill Company are just constructing an electric railway around their entire works for the purpose of testing electric cars turned out at their works. The road will possess sharp curves and as heavy grades as are found on ordinary street car lines. Current will be supplied from their own plant at the works.

The company are building a large number of cars and trucks for the following companies: Lynn & Boston Railway Company, Lynn, Mass.; Wilkesbarre & Wyoming Traction Company, Wilkesbarre, Pa.; New Britain Tramway Company, New Britain, Conn.; Washington, Alexander & Mt. Vernon Railway, Washinton, D. C.; Scranton Traction Company, Scranton, Pa.; Hornellsville & Canastota Railway, Hornellsville, N. Y.; Lakeside Railway Company, Montgomery, Ala.; Columbia Street Railway Company, Columbia, Pa.; and Central Construction Company, Wheeling, W. Va.

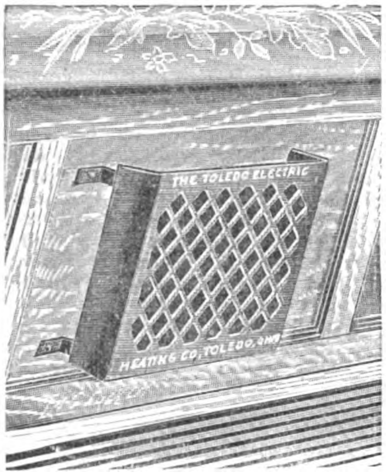
CHEAPER BEACON LAMPS.

The Beacon Vacuum Pump and Electrical Company, of Irvington street, Boston, and 141 Liberty street, New York, make this week an important announcement with regard to the reduction of prices of incandescent lamps made by them. They now offer their 16 c. p. lamps at 35 cents, on all orders beginning with as small a quantity as 200 lamps, which may even be in assorted sizes; terms net, 30 days. They also offer, on similar conditions, their 16 c. p. anchored filament railway lamps at 40 cents. This is an excellent offer, especially for those who have not yet tried the Beacon lamps, for whose life, brilliancy and minimum of blackening some very remarkable claims have lately been made and sustained.

THE TOLEDO ELECTRIC HEATER.

THE TOLEDO ELECTRIC HEATING COMPANY, of Toledo, O., are manufacturing a heater for electric street cars for which many strong claims are made.

These heaters are 13 inches long, 10 inches high and 8 inches thick, made to screw on the riser under the front edge of the seat next to the floor of the car. Four are used in an ordinary street car, running in a series of two so that two of them can be cut off when desired. They can also be made to run in a series of three for cars over twenty-one feet long. One and one-half amperes are used for two heaters, making three amperes for four heaters in an ordinary car and four and one-half amperes per car where six heaters are used. The switches and fuse box can be placed in any part of car. The price per car of four heaters is $20, making $5 apiece for each heater. Switches and fuse box to go with each set of heaters.

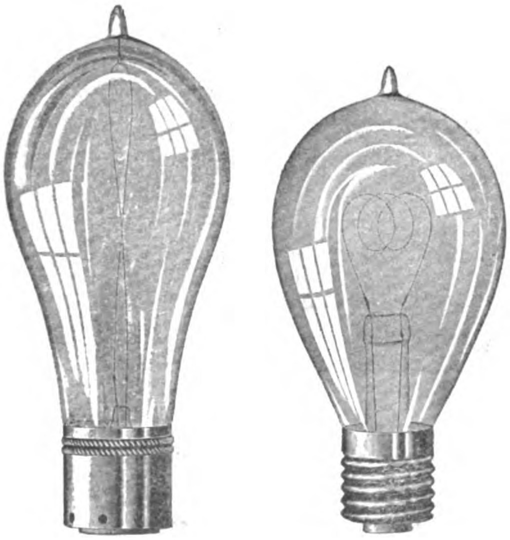


THE TOLEDO ELECTRIC HEATER.

The accompanying illustration shows one of these heaters placed on the "riser" beneath the seat of a car.

NEW LAMPS OF THE GENERAL ELECTRIC CO.

THE demand for a thoroughly high class incandescent lamp, especially adapted to the lighting of street cars, or for use on power circuits, has been steadily growing during recent months. At the lamp works of the General Electric Company a series of experiments in the direction of satisfying this demand have lately been made with entire success. The outcome of the experiments is three special types of lamp to satisfy the exacting requirements of railway and power work.



FIGS. 1 AMD 2.—GENERAL ELECTRIC CO.'S RAILWAY LAMPS.

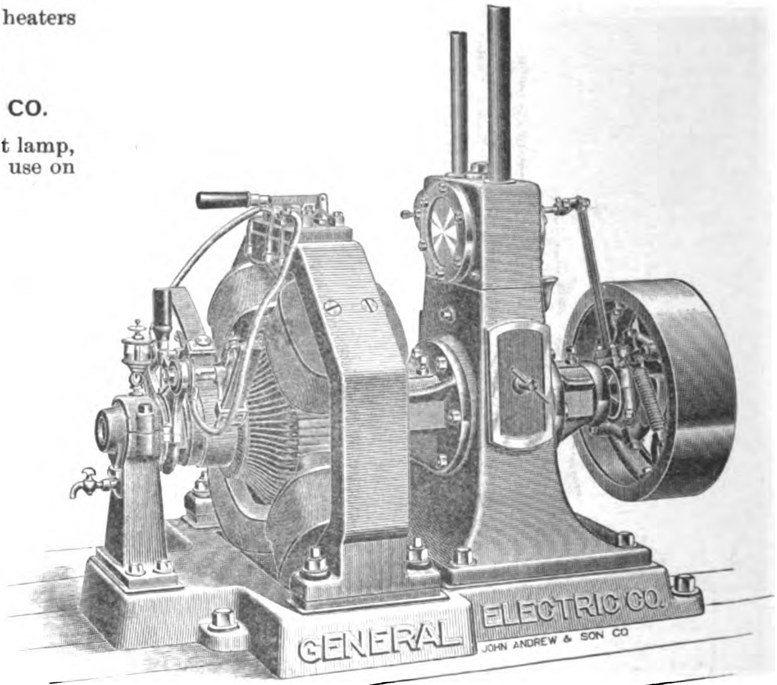
The first lamp is the straight unanchored filament lamp, differing in no way in appearance from the ordinary incandescent lamp. This lamp is rated according to the amount of current consumed, and only those consuming the same amount of current should be used in any one series. In the anchored filament lamp, Fig. 1, the chance of breakage of the filament by sudden contact with the glass of the bulb caused by motion of the car, is, it is claimed, entirely obviated. The design of the spiral filament lamp, Fig. 2, is the most novel and most pleasing. As will be seen the filament is made in three spirals, mounted on a heavy glass centre, and requires no extra support.

Great care is exercised in the manufacture of the two last named lamps in order to render the resistance exactly the same throughout each form, so that any "spiral" or "anchored" filament lamp may be used with others of similar form. Neither one, however, is intended to be used in series with the others.

A NEW DIRECT COUPLED GENERAL ELECTRIC ENGINE AND DYNAMO.

THE direct coupled generator and engine in one compact set, is, under conditions of restricted space and position, the ideal electrical plant. The illustration shows a small, direct coupled generating set, recently perfected and manufactured by the General Electric Company, and representing the result of two years of careful practical experience. For marine installations, where a separate engine is indispensable to drive the generator, these sets are especially adapted. As cheap as, if not even less expensive than belted plants, they can be readily fitted to positions where a belt driven dynamo and engine could not find a sufficiency of space. Compact and simple in arrangement, their suitability for small isolated plants in hotels and buildings, where belting is objectionable, is undeniable.

Under exhaustive tests, the engine shows a very high economy for machines of this size, and its simplicity is such as to reduce the attention necessary to a minimum. The generator is of the familiar General Electric Company quadripolar type, compound wound, having a regulation automatic within two per cent. over the entire range from no load to full load. The commutators are cross-connected, so that only two brushes, 90° apart, are used. The rheostat is of the new iron frame incombustible type. The engine and dynamo are both provided with self-oiling bearings.



DIRECT COUPLED GENERAL ELECTRIC ENGINE AND DYNAMO.

The sets are manufactured in 4, 8, 15, 30 and 50 kilowatt capacities.

THE
Electrical Engineer.
VOL. XIV. DECEMBER 14, 1892. No. 241.

THE LIFE WORK OF WERNER VON SIEMENS.

THE ocean cable, which he did so much to make practicable and perfect, brought to this country last week the news that Werner von Siemens had died in Germany at the ripe age of 76, after a life full of work and honors, embracing in its range of activity every practical advance made in electrical engineering during the last fifty years from the telegraph down to the electric railway. Few men have done as much as he for the practical applications of electricity, and his achievements will live long after him. The electrical industries which he helped to establish, with his wonderfully talented brothers, William and Charles, are among the largest and foremost of their kind in Germany, Austria, England, and Russia; while the current year has seen the United States included directly within the sphere of Siemens influence and energy, by the transference of part of the spare capital and technical force of Siemens & Halske to Chicago, where a large factory has been equipped and started for the production of their dynamos, motors, etc.

Werner Siemens's work was spread over a large variety of subjects, but his chief fame rests upon his contributions to electrical science and to electrotechnics. Even among these we must limit ourselves to the most important only—they are so numerous. It was in 1842, that is, two years before Morse operated his first line between Washington and Baltimore, that Siemens, then a second lieutenant in the Prussian army, and only 26 years old, took out his first patent for a "Process of Making Gold Plating Solutions," and shortly after he developed with his brother, Chas. W. Siemens, and Prof. Himly, of Göttingen, a method of plating which was taken up by the Elkingtons, of Birmingham, and worked successfully. At that time, it must be remembered, electro-plating was largely occupying the attention of electric workers, and it was in this field that Siemens naturally sought for the most immediate returns for his labor. He was young and poor.

The advent of the telegraph, however, and the success which it immediately scored must have impressed Siemens with the great future in store for this department of electrotechnics. It was little wonder, therefore, that he turned to this subject with energy and enthusiasm. As early as 1847 we find the young Hanoverian applying for a patent on a method for preventing the sluggish action of the receiving magnets of telegraph instruments, and for another patent on an improved printing device. It would take us too long to enter into the details of these mechanisms and of many others which followed. Among these were a repeater invented in 1854, and many improvements in the manufacture of submarine cables, Siemens being among the first to recognize the value of gutta percha for submarine work.

Early in his career Siemens had associated himself with a clever mechanic, Mr. Halske, and thus were laid the foundations for the great firm of Siemens & Halske. As early as 1848 that firm undertook a large contract for a telegraph line and its apparatus between Frankfort and Cologne, and at the great International Exhibition in London in 1851, they showed a varied assortment of telegraph instruments and appliances.

But it is probably in connection with the dynamo electric machine that Werner Siemens's name is most widely known, his discoveries in regard to it constituting his chief claim to be placed among electrical worthies. As early as 1856 he had arrived at the form of armature familiarly known as the Siemens double-T armature, which he used in connection with a needle telegraph apparatus, the armature being rotated in the usual field formed by permanent magnets. It was nearly nine years afterwards, on the 17th of January, 1867, that Prof. Magnus communicated to the Royal Academy of Sciences, at Berlin, a paper entitled, "On the Transformation of Magnetic Energy into Electric Current Without the Use of Permanent Magnets." This communication describes the great discovery made by Werner Siemens, namely, that the current generated by the armature could be utilized for the energizing of the field magnets, and that separate independent magneto exciters, such as had been employed theretofore, were no longer necessary.

Although first brought to the attention of the public in 1867, the earliest recorded mention of this discovery by Siemens appears to have been in a letter from him to his brother William Siemens in London, dated Dec. 24, 1866. In this letter he describes the building up action that takes place in dynamo machines, and there we find this prophetic paragraph. "The effect must, with proper construction, be enormous. The thing is very capable of development, and may form a new era in magneto-electricity. In a few days the apparatus will be ready, and magneto-electricity will by this means become cheap, and electric lighting, galvano-metallurgy, and even small electro-magnetic machines, receiving their power from large ones, may become possible and useful." It is not often given to men to see their predictions verified in the way that has fallen to the lot of Werner Siemens. Without detracting from Siemens's just fame in this discovery, it may be noted in passing that Prof. Moses G. Farmer ran him close with the independent discovery of the principle in this country.

With the advent of electric lighting, Siemens devoted considerable attention to this department, and to him is due the ingenious idea of the differential arc lamp, the constructive details of which were carried out by von Hefner-Alteneck. To Siemens is also due the successful carrying out of the first European electric railway at the Berlin Exposition in 1879, and to the European roads which immediately followed this successful experiment.

But besides his numerous arduous duties in the mechanical and financial world, for he was perhaps as able a banker as he was an engineer, Werner Siemens had also found time for study and speculation on the conditions of mankind as they present themselves in the light of the newer electrical development. But a few years ago, in discussing the condition of the earth's inhabitants when our available coal shall have been exhausted, Siemens pointed out that the electric current might afford means for fuel supply, in the electrolytic generation of oxygen and hydrogen, or again, in the decomposition of salts and the obtaining of sodium, potassium, etc., which could be used as combustibles, the natural forces, such as waterfalls, being employed to drive the electric generators.

As to the possibility of the manufacture of nitrogenous food products, Siemens has also pointed out that as ozone can be generated electrically, and as it has a marked affinity for nitrogen, it would seem to promise at least one method of obtaining a combination, which might, by the aid of chemistry, furnish us with digestible nitrogenous materials.

Dr. Siemens was a member of the Prussian Order of Merit, and the late Emperor Frederick conferred upon him a patent of nobility. The dignity of Doctor of Philosophy, *honoris causa*, was awarded him by the University of Berlin in 1860. He was the recipient of a great many honors at home and abroad, and was a member of several of the European learned societies. He was well known to American electricians, to one of whom, Mr. W. J. Hammer, we are indebted for the use of the autograph portrait accompanying this article, the photograph having been presented to Mr. Hammer by the Doctor on the recent occasion of their last meeting. It is a very faithful likeness.

LIGHTING PARADE FLOATS BY STREET RAILWAY CURRENT.

BY JOHN H. BARNARD.

During a trades parade held in Wilmington, N. C., on November 30th, a novel method of lighting was employed on several of the floats. Incandescent lamps were freely distributed about them, connected up five in series. Contact was made with the trolley wire of the Wilmington Street Railway Company by a very simple trolley and with the rails by a little car, made to fit the gauge of the track, which was towed under the wagon on which the float was built. The result was extremely satisfactory, and presents a very simple solution of the difficulty of lighting up floats in night parades. Thirty lights of 16 c. p. gave excellent illumination to large floats. Among the floats lighted electrically was that of the Wilmington Street Railway Company, which represented Benjamin Franklin drawing electricity from the clouds. The kite was attached to a long bamboo pole, and above the kite, and hidden by it was a large contact shoe made of sheet copper. Along the pole, which was carefully covered, were strung fourteen 16 c. p. lamps, representing the string, and the fifteenth was dropped into the Leyden jar. This float, being built on a flat car ordinarily used for construction purposes, the ground connections were easily made through its wheels. This method of lighting proved so satisfactory that no doubt every float of any consequence will be so lighted in the parade of next year.

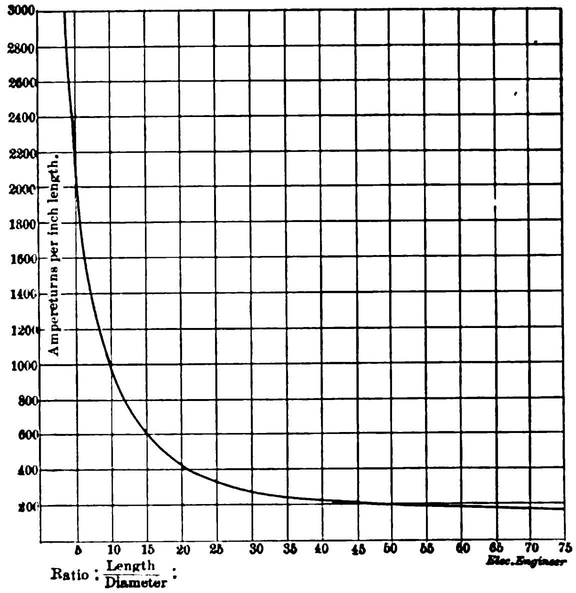
A CURVE FOR ASCERTAINING THE AMPERE-TURNS REQUIRED FOR MAGNETIC SATURATION.

BY

Chas. Steinmetz.

In response to inquiries which are frequently addressed to the writer and in view of the importance of the subject, he has thought that a few words on the ampere-turns required to magnetically saturate a piece of iron of known diameter would prove of value to the readers of The Electrical Engineer.

The ampere-turns required to bring an iron piece practically up to magnetic saturation, can not be expressed as a numerical value, since they depend mainly upon the size and especially upon the *shape*, of the iron piece. In a closed ring, or a rod, the length of which is more than one hundred times its diameter, a M. M. F. of 150 ampere-turns per inch length of the iron piece will, with ordinary good wrought iron, bring the magnetization up to within 10 per cent. of absolute saturation.



With shorter rods, very much larger M. M. F.'s are required, and the M. M. F.'s required depend much more upon the dimensions of the iron-piece. Approximate values of the M. M. F.'s, in ampere-turns per inch length of the iron piece, are given for the different values of the ratio: $\frac{\text{length}}{\text{diameter}}$ of iron piece, in the accompanying curve, though these values can be considered only as first approximations.

A NEW ELECTRIC LIGHT PLANT FOR ST. LOUIS.

St. Louis is to have a large new electric light station. Plans have been approved and contracts already let for the machinery, and work will be commenced shortly. All wires will be underground and the entire equipment will be in accordance with best modern practice.

THE ENGINEERING DETAILS OF THE NEW YORK-CHICAGO LONG-DISTANCE TELEPHONE LINE.

BY

Jos. Wetzler.

I.

BRIEF as has been the time during which the telephone has entered as a factor in commercial and social life, its influence on both can be said to be hardly less than that of the telegraph itself. Indeed, if we analyze more closely the extent to which the telephone is used, comparing the number of calls by the telephone with the number of messages sent by the telegraph, it would be found that the proportion is vastly in favor of the telephone. In the early days it was taken for granted, though no reason was assigned therefore, that the telephone would be limited to communication between points within the limits of a city, notwithstanding the fact that one of the early demonstrations of its power was the communication between New York and Philadelphia, and even between points of greater distance.

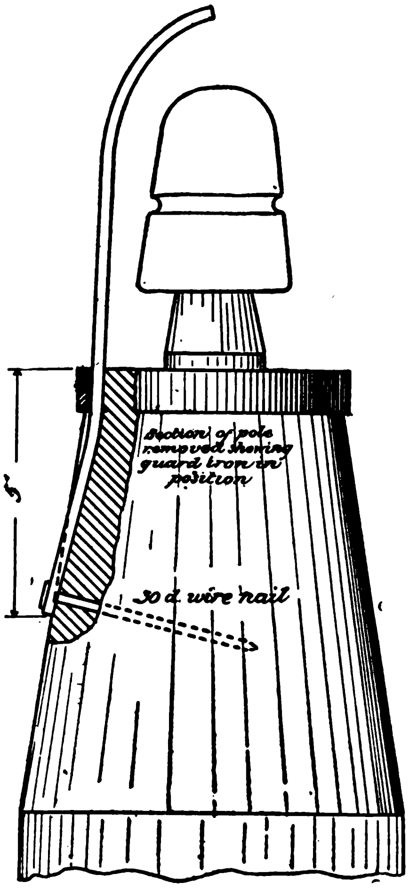


FIG. 2.—GUARD IRON ON TOP OF POLE.

But it was early surmised that if regular telephonic communication were provided between distant cities, and subscribers offered facilities for communication which would involve no more trouble than that experienced in the ringing up of a local correspondent, a business could be built up which could be made profitable. This idea, which had lain dormant for some time, was seriously taken up in 1885, when the American Telegraph and Telephone Company, familiarly known as the Long Distance Company, was organized, and its active management placed in the hands of Mr. E. J. Hall. The first line was built between New York and Philadelphia, and its success was so immediate and spontaneous, that if any doubts had previously existed as to the commercial value of long-distance telephone lines, they were dispelled; and the confidence of the officers of the company in the correctness of their estimates was so strengthened that additional lines between Boston and New York were immediately constructed.

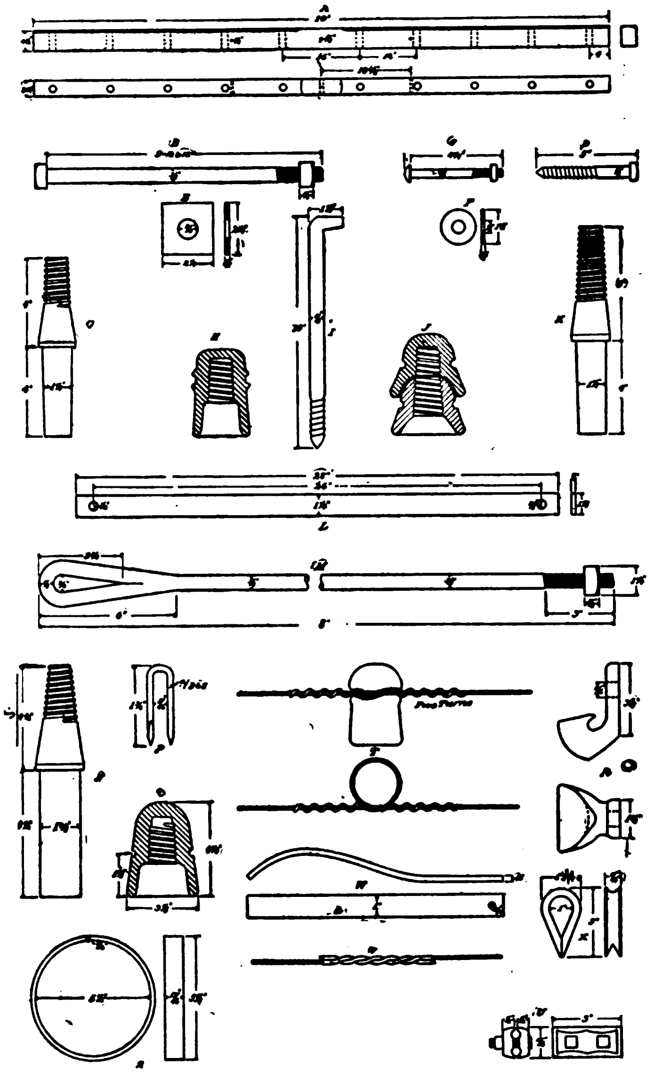

FIG. 1.—DETAILS OF NEW YORK-CHICAGO TELEPHONE LINE CONSTRUCTION.

The history of the development of the long-distance lines since that time is familiar to our readers, and need not be further enlarged upon here, but a recent important addition to which due reference has already been made in these pages, merits more than ordinary attention. We refer to the line recently opened between New York and Chicago, involving a distance of 950 miles, which represents a stride in telephony, the effect of which it is difficult to estimate at this early stage.

II.

Up to the time at which the New York and Chicago line had been contemplated, the longest sustained successful telephonic transmission had been about 500 miles, and it was, therefore, a matter for no small consideration, and one, the importance of which, the company well recognized, that the operation of a line almost twice this distance should be successful at the very start. The previous experience of the company stood it in good stead, but the rules which had been laid down for the calculation of the size of wire required for the transmission of speech had been found to be at such variance with the actual practice of the company, that its engineers were necessarily obliged to observe the greatest caution in their recommendations. The most commonly accepted rule for telephonic transmission is that laid down some few years since by Mr. Wm. H. Preece, chief engineer and electrician of the British Postal Telegraphs, which is as follows :

When $K\ R = 15{,}000$, speech becomes impossible.
" " " $= 12{,}500$, speech becomes possible.
" " " $= 10{,}000$, speech becomes good.
" " " $= 7{,}500$, speech becomes very good.
" " " $= 5{,}000$, speech becomes excellent.
" " " $= 2{,}500$, or under, speech becomes perfect.

This rule, it must be pointed out, is entirely empirical, and as such, as frequently turns out to be the case, is only safely applicable to circuits whose length is within the limits of those by which the rule was formulated. As proof of this we may remark here that the telephone line between Paris and London was built according to this rule, and the $K\ R$ constant of 7,500 was adopted. When the line was finished it was found that transmission over it was very much better than the formula indicated, which went to prove that the rule apparently did not apply to that particular line. But long before the completion of the Paris-London line, it was well known to the engineers of the Long Distance Company, that this rule was not generally applicable, for the reason that the circuits at their command showed that transmission was possible over lines having a very much higher $K\ R$ constant. Thus among the experiments tried by them was the coupling up of lines aggregating in length from 650 to 1,100 miles. The results obtained are shown in the following table :

650 miles, excellent transmission with $K\ R =$ 31,000.
750 miles, good transmission with $K\ R$ = 45,000.
885 miles, poor transmission with $K\ R$ = 62,000.
1,100 miles, no transmission with $K\ R$ = 91,000.

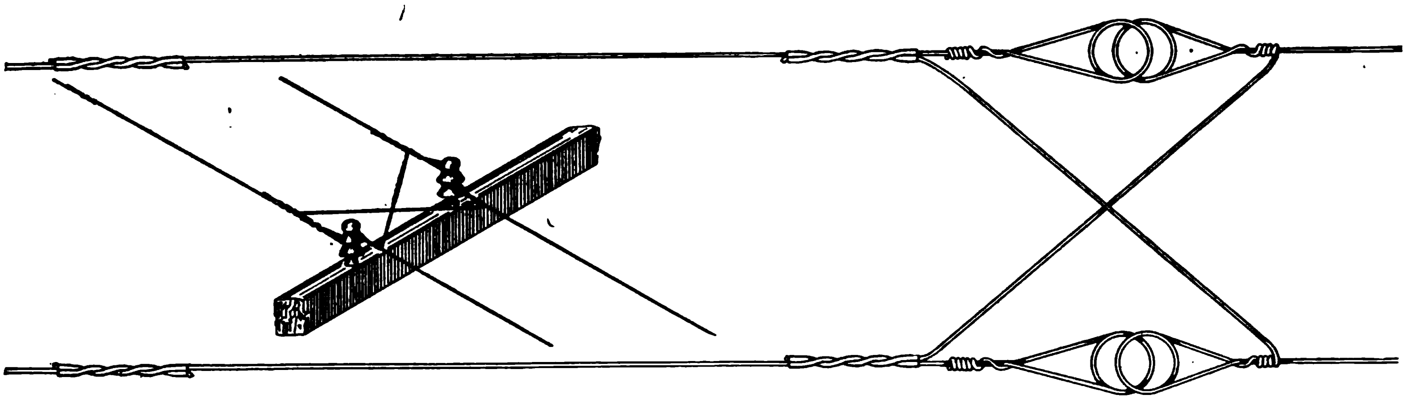

FIG. 5.—METHOD OF TRANSPOSING WIRES, NEW YORK-CHICAGO TELEPHONE LINE.

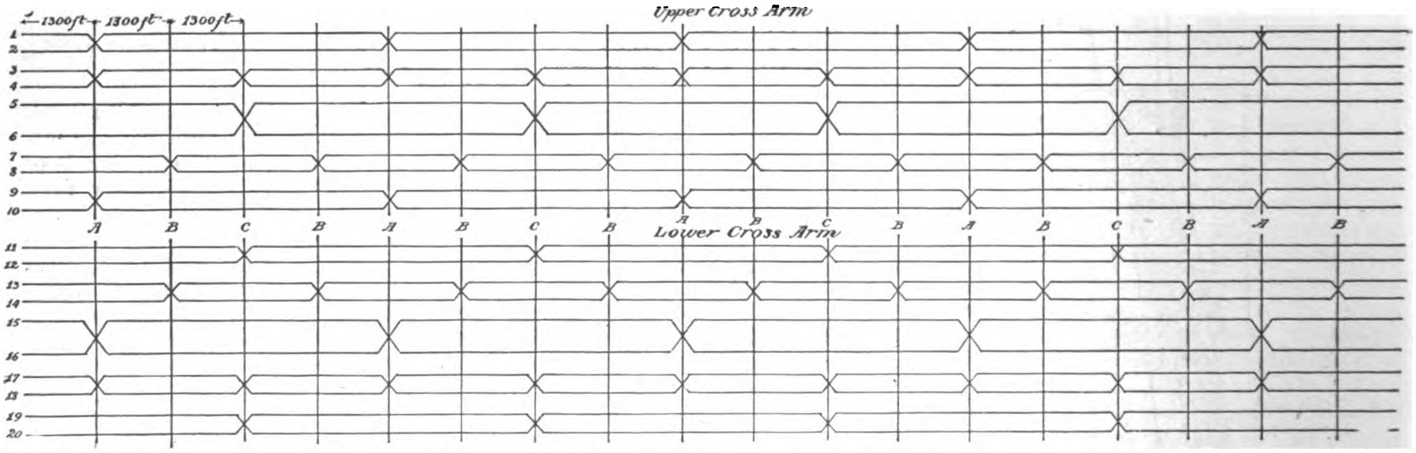

FIG. 6.—SCHEME OF CIRCUIT TRANSPOSITIONS, NEW YORK-CHICAGO TELEPHONE LINE.

These experiments were made with a "solid-back" transmitter, and three cells of Fuller battery, the usual equipment of the long-distance telephone set.

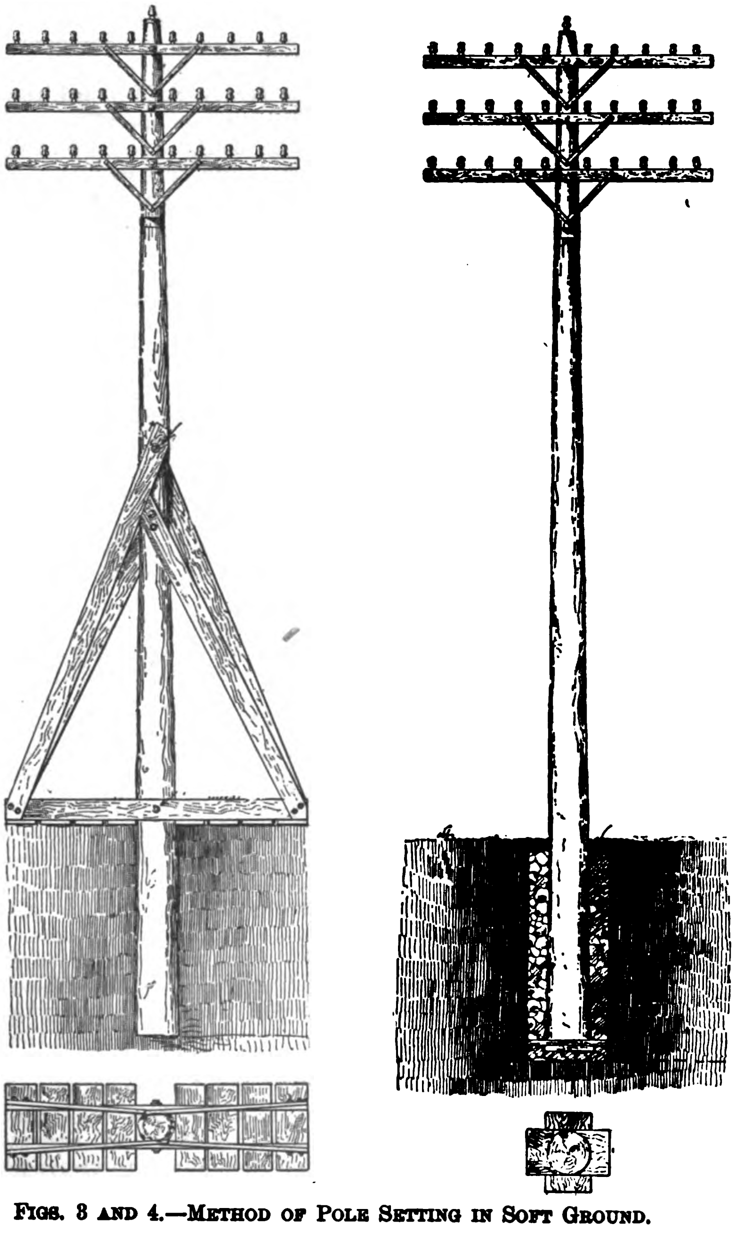
According to the formula enunciated by Mr. Preece, it would require a wire weighing nearly 2,000 pounds to the mile in order to communicate with Chicago, and it was not to be wondered at, therefore, that the engineers of the Long Distance Company hesitated in applying this rule. The results of their own experience, however, was such as to give them confidence in the selection of a greatly reduced size of wire, and after due consideration it was determined to select a No. 8 B. W. G. wire, having a diameter of .165 inch, and weighing 435 pounds to the mile. This wire has a resistance of 2.06 ohms per mile, and a capacity of .0158 microfarads per mile, with wires strung 35 feet above the ground. 1,000 miles, practically representing the distance between Chicago and New York, has a $K\ R$ constant of 32,000. Yet notwithstanding this enormous excess over the limiting figure laid down by Mr. Preece, it was adopted and the line built. The results obtained are now well known, but even before the building of the line was begun the engineers of the company were firm in the conviction that it would prove to have such excellent speech transmitting qualities, that it would give a sufficient margin to make it possible to add on other lines at the end and possibly secure communication to cities beyond Chicago, such as Minneapolis, St. Paul and St. Louis; while, on the other hand, it would leave large margin for the attachment of local lines within a radius of 100 miles from Chicago.

As another proof of the inadequacy of the transmission formula, as laid down, it is only necessary to consider the following $K\ R$ constants for lines which are now, and have been for some time, in daily operation, as follows:

Boston and Washington,	$K\ R = 26{,}250$.
Boston and New York,	$K\ R = 12{,}100$.
New York and Philadelphia,	$K\ R = 2{,}000$.

From the above it is evident that while the lower figures given by Mr. Preece agree thoroughly well with the results obtained on the long-distance lines, the higher figures are greatly at variance with it, the circuit between Boston and Washington, for instance, exceeding Mr. Preece's figure for speech "impossible" by nearly 75 per cent.

As some question might be raised as to the manner in which the $K\ R$ constant is here calculated, it might be well to point out the fact that Mr. Preece multiplies the total resistance of the circuit by the capacity of one of its wires measured against its mate, and estimates that the capacity of one wire measured against



Figs. 3 and 4.—Method of Pole Setting in Soft Ground.

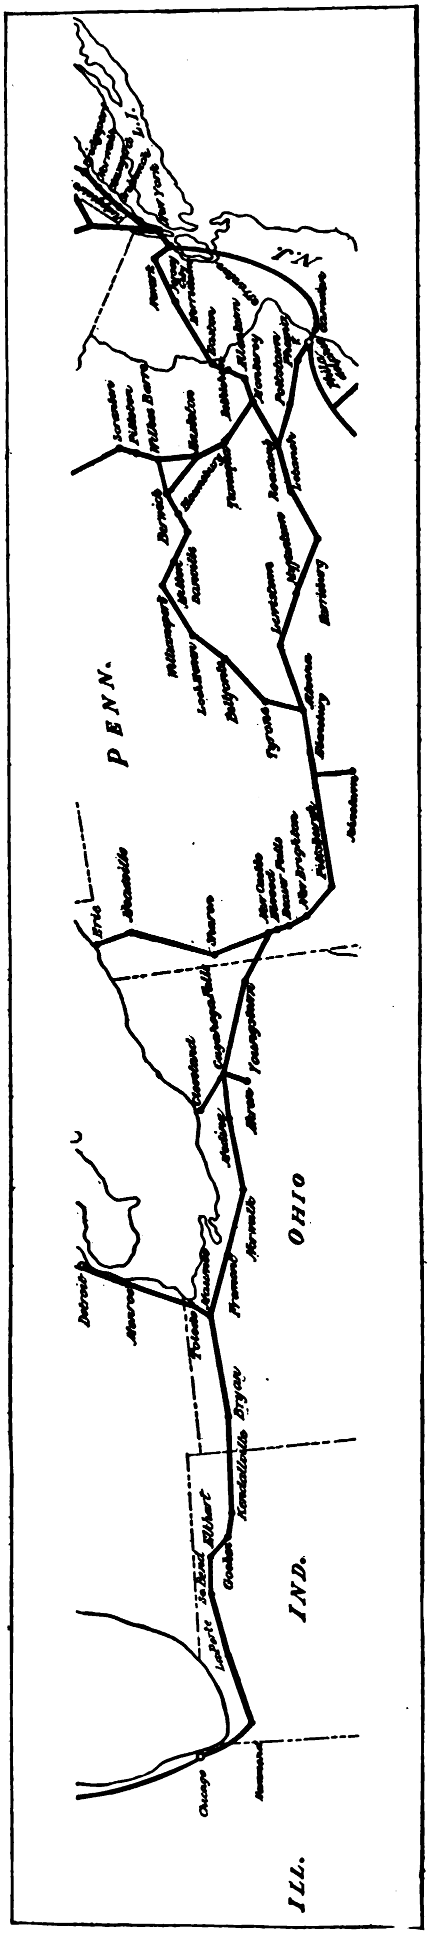


Fig. 7.—Detail Map of New York-Chicago Long-Distance Telephone Lines.

its mate is one-half of what it would be if measured to ground. In the calculations made by the Long-Distance engineers, they have taken the resistance of one of the wires of a metallic circuit, measured in ohms, and multiplied it by its electrostatic capacity measured in microfarads, to ground. The difference evidently is one of method only, the result being the same. It might be well to point out here that one wire measured against its mate, as done in the calculations of Mr. Preece, is never found to be exactly one-half of the capacity when measured to ground, being usually found to be from 60 to 65 per cent. of that quantity.

III.

The building of the line having been determined upon, the questions of the details of construction to be adopted were given most exhaustive study. In this respect the experience of the company in its past work has also stood it in good stead, with the result that it is fair to assume, that the construction adopted will afford a line of the most permanent character.

The line is built of standard poles 35 feet long, of the best quality of live, green cedar wood, peeled, and the knots trimmed close. This length of pole permits it to extend not less than 26 feet above the surface of the ground.

The cross-arms employed are of thoroughly seasoned, straight grained Norway pine, 10 feet long, 3½ inches thick, and 4½ inches deep, as illustrated at A in the diagram Fig. 1, which shows the auxiliary details of construction complete. These cross-arms are given two thorough coats of metallic paint, and are braced with two galvanized iron braces, shown at L, Fig. 1, which are attached to the cross-arms by means of galvanized iron carriage bolts, shown at C. These cross-arms are fastened to the pole not in the usual way, by means of fetter drive screws, but by a galvanized iron bolt shown at B, the pole being bored for the purpose, and the bolt passing entirely through. Washers under the head and nut prevent abrasion of the cross-arms and the pole.

The insulator pins are made of clear split locust, 1¼ inches in diameter, and having the general outline shown at G. The transposition pin is shown at K. The pins are nailed to the cross-arms with heavy galvanized iron wire nails driven in straight from the middle of the side of the cross-arm.

The type of insulator employed is the regular standard white glass American Telegraph and Telephone Company's insulators, shown at H. For the guard wire the 20-ounce Western Union double petticoat insulator, without petticoat, is used as shown at O, Fig. 1. The transposition insulator is of the Hibbard pattern, of white glass, and is shown at J.

On the corner poles guard irons are employed as shown in Fig. 2, and at W Fig. 1, passing under the ring at the top of the pole. Every tenth pole is furnished with a lightning rod made of No. 6 galvanized iron wire. These rods are fastened to the pole every two feet by iron staples extending from the top to the bottom, and at the latter end they are given two hand turns.

In ordinary good ground the poles are set at distances of 130 feet to a depth of 6 feet, and on curves to a depth of 6½ feet. Where the earth is soft so as to prevent proper tamping the constructions illustrated in Figs. 3 and 4 have been adopted.

The method of tieing the wires is shown at T Fig. 1. Here it will be noticed that one side of the tie wire passes around the line wire and makes five complete turns. The joints in the copper line are made with McIntire sleeves, each sleeve being given three complete twists as shown at V, Fig. 1.

IV.

In laying out a telephone line great care must, of course, be taken to avoid cross-talk and other disturbing influences, which militate so much against clear enunciation, and makes wires noisy. For this purpose it is necessary to transpose the wires at proper intervals, and to accomplish this transposition insulators are employed. Fig. 5 shows the method of carrying out the transposition. It will be noted that the line coming from the left is dead-ended on the upper insulator, and continued by means of a cross-over connector to the neighboring line, its mate. This line is also dead-ended on the other upper insulator. In the same way the other two sides are joined so that the position of the conductor on each side of the cross-arm is reversed. The present line carries two cross-arms which will eventually carry 10 wires each, and the transpositions employed on the upper and lower cross arms are clearly shown in Fig. 6.

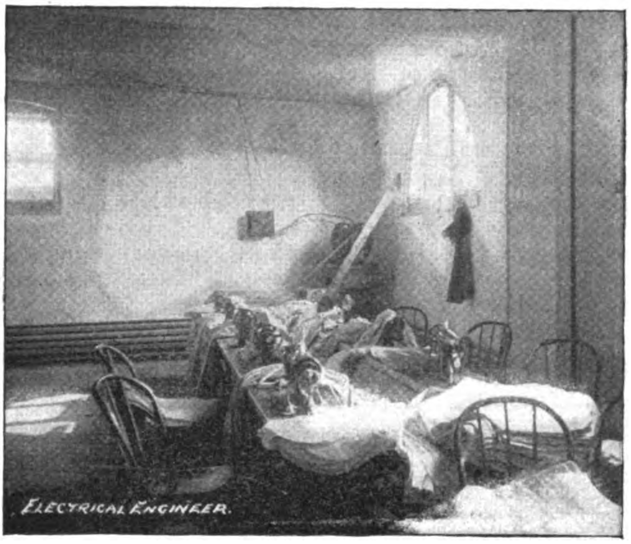
The route over which the line has been constructed is illustrated in the map, Fig. 7. The line, it will be noted, passes through, or is connected by short branches and loops with, the most important cities between New York and Chicago.

We have already referred to the credit which must be accorded to the enterprise and management which has made the New York-Chicago line a possibility, but we cannot close this description without a brief mention of those who have had immediate charge of the work and have brought it to a successful completion. Mr. E. P. Meany, assistant general manager of the Long Distance Company, has had charge of the construction work of the entire line, and F. A. Pickernell, engineer of the company, has had general charge of the electrical and mechanical working out of the system; while Mr. A. S. Hibbard, the general superintendent, has had charge of its operation and maintenance. The company is to be congratulated on the possession of the services of men so thoroughly competent, and whose work will no doubt prove of permanent value to the profession at large.

THE SHERIDAN ELECTRIC POWER AND OFFICE BUILDING, DENVER, COL.

The growth of any city is marked by a diversification of its industries, and the growth is helped, not less than the diversification, by the ability to obtain power readily in small quantities. The number of manufacturers who wish to run a steam plant of their own is in reality very limited, and hence small industries have often been bunched together, under very disadvantageous conditions, in large buildings whose only recommendation was that they could furnish power from some large engine by means of long lines of shafting and belts. Every large city in the Union has such buildings to-day, and their number would go on increasing were it not for the improvement in gas engines and for the still greater revolution or advance effected by the perfection of electric motors and the flexibility of electric power distribution. The result already of the introduction of electric motors has been that consumers of power in small quantities are no longer compelled to herd together in quarters of the city frequently unsuited to their class of trade or product, but can now locate in desirable regions and enjoy facilities of commerce hitherto undreamed of.

The new departure has gone even further, and has already been pushed to its legitimate conclusion by enterprising engineers and capitalists. In other words, we are beginning to see the erection of fine buildings, in choice city districts, where the current generated by a plant in the basement is distributed to every floor and is at the service of every tenant, who can apply it to any work short of the heaviest. As an example of what is now being attempted in this direction, we illustrate the Sheridan Building in Denver, built last summer by Mr. J. H. Ernest Waters, a mining engineer who has done much to promote the application of electricity to mining work in the West. His plants in the Sheridan and Belmont Consolidated mines, in Colorado, have already been illustrated and described in THE ELECTRICAL ENGINEER. His success in the mining field enabled Mr. Waters to turn his attention to real



COLORADO OVERALL FACTORY, SHERIDAN BUILDING, DENVER.

estate, and the Sheridan Building exemplifies his ideas as to what a progressive capitalist can do in any city to encourage the development of the smaller industries which do so much to render prosperity stable and accumulative.

Mr. Waters's plan at the outset was to erect and equip a building suitable for occupancy by such smaller manufacturers as brass finishers, working jewelers, lithographers, platers, photo-engravers, printers, etc., whose business, though requiring power, did not warrant the cost of the installation of and attendance on independent steam plants.

THE WESTERN PLATING AND MANUFACTURING CO.

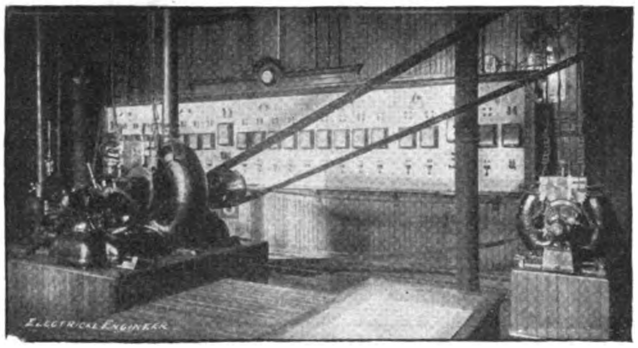
He was ably seconded by Baeressen Bros., leading architects of Denver, and Mr. H. L. Lufkin, of New York, who designed and drew up the specifications for the electrical plant, switchboard, and distributing system. The entire electrical equipment was furnished by the C. & C. Electric Motor Company. The building is shown on page 570. It is in a thriving quarter of the city, and would do credit to any thoroughfare. There are four floors.

The generating plant consists of a Frazer & Chalmers Corliss engine of 150 h. p. capacity, and a Straight Line engine, high speed, of 40 h. p. capacity. There are foundations in the engine room for two 50 kilowatt dynamos, only one of which, however, has thus far been installed. The 50 kilowatt dynamo is used through the daytime for operating both the power and lights all over the building, and is wound for a pressure of 115 volts. It is driven from a countershaft which in turn is driven from the 150 h. p. engine.

Directly connected by belt to the 40 h. p. Straight Line engine is a 20 kilowatt dynamo used for lighting after the large engine is shut down at about 5 or 5.30 p. m. The stores in the front of the building are thus furnished with light until 11 or 12 p. m., as the case may be; and such hall lights and small powers are furnished as are required for overtime work. The switchboard arrangement is such that the small dynamo is thrown on or off the power circuits as well as the lighting circuits, as conditions require.

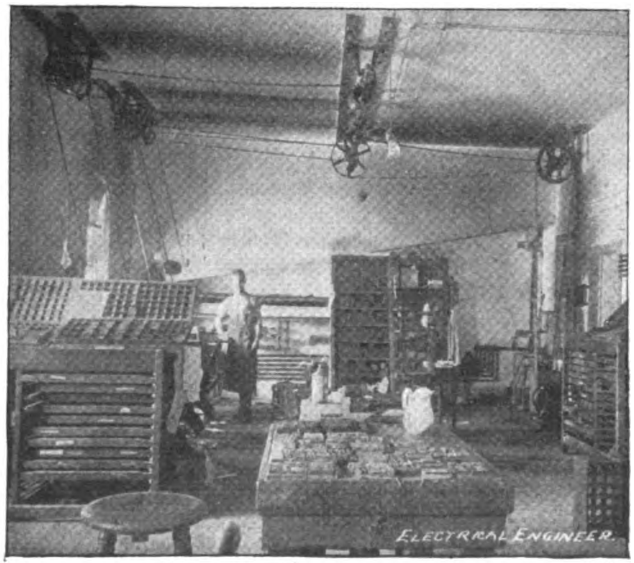
The boiler plant comprises two 60 by 16 Frazer & Chalmers tubular steel boilers.

The marble switchboard is a very handsome piece of equipment about 15 or 20 feet long, with an independent power



PART OF THE DYNAMO ROOM.

circuit arranged from the switchboard to each tenant in the building, thus giving the engineer at all times the opportunity of checking off the power that is used by each tenant. Observation of the general action of the indicator needle also enables him to detect the development of any trouble, and gives the ability to locate and remedy it. The



QUEEN CITY PRINTING CO.

building is wired throughout with American Electrical Works triple braid wire strung on porcelain insulators.

On the ground floor of the building are situated also a number of large stores, with which the generating plant in no wise interferes. One of the stores is occupied by the Kennedy & Pierce Machinery Co., extensive dealers in mining and other apparatus; Anfell & Co., druggists; a large grocery firm; and by the "Nomad" saloon, which prides itself on being the most gorgeous bar in a city where excellence of the kind is far from uncommon. We mention these branches of trade and "industry," and those which follow, in order to indicate clearly the variety of work to which the power furnished is being applied. On the second floor are the offices of Waters Bros., mining and mechanical engineers; the Beebe Engraving Company; the Denver Printing Ink and Roller Works, and a room occupied by the Columbian Exposition Commissioners. We illustrate some of the rooms on the various floors, our engravings showing a plating establishment, a printing office and an overall factory. One or two others would have been illustrated, as good examples, but unfortunately—or fortunately—the motors are not so much *en evidence* in them. Electric motors are such handy things for stowing away in awkward places, that the temptation to "hide their light under a bushel" cannot be resisted. At the time the data was given us for this article there were 15 large airy rooms ready for occupation and being rapidly rented. They range in size from 18x60 feet to 20x90 feet, and each has its 5 h. p. motor, electric light, artesian water and steam heat. Any tenant requiring more power can of course get it in just such units and quantities as are necessary to drive the machines or tools. The motors are run from 7 A. M. until 6:30 P. M., under the terms of the lease, and special, easy arrangements are made for tenants needing power at night. There are two electric elevators in the building, one for freight, serving the railroad tracks on the north side of the building, and the other serving to deliver manufactured goods to wagons on the south side of the building. There is thus every facility for handling raw material and the finished product.

The Sheridan Building immediately adjoins the Union Dépôt and is at the foot of one of the principal business streets of the city. The present tenants express themselves as well pleased with the location and arrangements of the building, and we cannot but believe that such facilities must draw to Denver from the East and elsewhere many promising young industries in search of power and a market. It seems to us, also, that Mr. Waters has made an innovation in which he should find many imitators, for it is no longer necessary to preach the benefits of electric power. The question nowadays is that of distributing and furnishing the power to those who ask for it. We have shown above one admirable way of solving the problem.

THE SHERIDAN BUILDING, DENVER, COL.

IS THE ELECTRIC DISCHARGE OSCILLATORY?

IN the experiments by Hertz, on electrical oscillations, and also in the experiments of subsequent investigators in the same field of research, Ruhmkorff coils have been used to propagate the electrical oscillations. It is well-known, however, that the oscillations in the sparks from a Holtz machine or a Leyden jar are far more rapid than those produced by the aid of a Ruhmkorff coil. Töpler, therefore, has endeavored to study electrical oscillations by the aid of a Töpler-Holtz machine, and with success. During his experiments he was led to examine the electric spark between a conductor and a surface of water, and he discovered that a spark under these conditions does not oscillate. He has therefore deduced the conclusion that it is extremely probable that the ordinary lightning discharge does not oscillate. A loud noise and a strong development of light in an electric spark are held by Töpler to be not, in general, criteria of the oscillatory character of the spark.

THE PROPOSED INTERNATIONAL ELECTRICAL EXHIBITION IN MILAN.

WITH regard to this proposed exhibition in 1894, the committee are now proposing to offer, in addition to the usual diplomas and medals, a "grand premium" for the most important invention and discovery in the field of electricity, having special regard to the long distance transmission of electric energy, and its distribution and transformation for industrial uses.

Vol. XIV. NEW YORK, DECEMBER 14, 1892. No. 241.

Nature is our kindest friend and best critic in experimental science, if we only allow her intimations to fall unbiased on our minds.—Faraday.

IS IT TO BE A RAREE SHOW?

IT has appeared from the statements of the electrical authorities of the World's Fair that the demand for space has led to the cutting down of the allotments asked for by exhibitors at home and abroad. From this fact, it might be inferred that the electrical display would be very fine; and the inference is true, but unfortunately, no small part of the space has been awarded to exhibits either of the raree show nature or to those that are in reality in the line of quack medicines. Some of them have been called "swindles." Admitting the good faith of the proprietors of these nostrums, it still seems to us to be an imperative duty on the part of the World's Fair administration to rule out such exhibits peremptorily. To give these exhibits a place at all, is official recognition of their validity and value.

If necessary, we shall specify later on the exhibits we refer to, though the management, with men like Prof. Barrett and Dr. Hornsby at the helm, ought to know them without any assistance. To show how the space is wasted, we will quote from one exhibitor of electric belts, etc., who says: "It is intended to show in addition to a complete line of our goods, the manufacture of the same. We intend to put in a full line of operators on our machines, and we shall turn out our completed articles in our exhibit." Another concern of the same character says: "Our work is devoted entirely to this line (magnetic shields) and the goods are what are known as vests, belts, insoles, etc. In our exhibit *we do not intend to show anything in the line of electricity*." But the most curious avowal of all is that of a Chicago doctress or "electric surgeon," who writes: "I will exhibit samples of my work—old women, with one side of the face young." Her invention is the eradication of wrinkles by electricity and her circular says: "I will remove wrinkles and crow's feet from one eye for any one free of all charge. You are under no obligation to have any more work done unless you so desire." As one generally does pay to be shaved on both sides of the face, at once, it seems likely that one would desire to have the environment of both optics rejuvenated at the same time. But such curiosities as these belts, shields, insoles and rows of ghastly old women are out of place among the regular exhibits of an educational exposition, and we suggest that they be relegated to the position of "side shows" beyond the grounds, or else be turned over to Barnum, Hutchinson & Bailey's Greatest Show on Earth.

ECONOMY OF ALTERNATE CURRENT PLANTS.

In a communication printed in another column, the manager of a small central station raises a very important question, in reference to the commercial efficiency of the alternating current plant as a whole, which has not hitherto received the attention it merits. While in the transactions of the learned societies and in the columns of the technical press, there has been no lack of able papers, and of no less able discussions upon the conditions of maximum economic efficiency in dynamos, in transformers, in lamps, and in conductors, yet the question of the economical conditions affecting the alternate current system with transformers as a whole, appears to have been almost completely neglected. It is now something like six years since the first commercial plant of this kind was installed in this country; many hundreds of them are in operation in all parts of the United States under almost every conceivable condition, and yet strange to say, the figures given by our correspondent are, so far as we are aware, the first which have been published giving the results of actual every-day work in a small station. The fact that these figures are distinctly unfavorable, does not necessarily prove that the system itself is at fault, but it does show that it is liable to unsuspected and hidden sources of loss, amply sufficient to account for the not infrequent financial failure of electric lighting enterprises which ought to be profitable, but are not. We shall welcome further communications on this subject, especially those containing facts and figures deduced without prejudice from the results of actual commercial work. As we have more than once pointed out, the margin of profit in electric lighting is still too small at best to admit of any avoidable waste or loss.

LONG DISTANCE TELEPHONY.

Regular and steady users of the telephone fail to realize what an important rôle it has already begun to play in daily life, and it is only when some new feat in telephony is accomplished such as the opening of the New York-Chicago Long-Distance line, that we are brought face to face with the fact that telephony is a progressive art with well defined stages of advance. This applies not only to the exchange apparatus but to that important branch of the service, the underground and overhead work. While the methods which have insured the success of intra-urban telephony were pretty clearly worked out some time ago, the establishment of communication between distant cities has been a work requiring the utmost caution in order, first, to attain good, commercial talking, and, second, not to exceed an investment which would leave a reasonable margin of profit. Taking the New York-Chicago line, for instance, an increase of thickness in the wire of only $\frac{1}{100}$ of an inch would have involved an increase in cost amounting to over $15,000. The laws of calculation as laid down, and generally accepted, if applied in this case, would have made the cost utterly prohibitive.

THE LIFE OF INCANDESCENT LAMPS IN ITS RELATION TO MERCURY AND METALLIC VACUUM PUMPS.

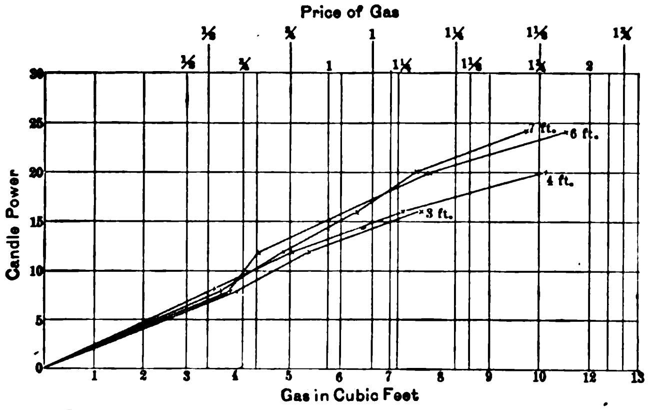
BY

G. A.

THE paper read by Prof. B. F. Thomas at the last meeting of the American Institute of Electrical Engineers has been criticised by incandescent lamp makers, by the gas interests and by the press. From the lamp makers' point of view, the paper is certainly worth more than average consideration. The three points brought out are:

1. That the so-called 16 c. p. lamp gives only 14½ candles. 2. That the efficiency is at least half a watt less per candle than claimed by the companies. 3. That lamps exhausted by means of a metallic pump showed less blackening than those exhausted by mercurial pumps.

To begin with the criticism of the daily papers and the gas companies, the *Boston Transcript* of July 26, said that "the gas-light interest has always maintained that the candle power of the incandescent electric lamp is not what it is represented," and these tests "as the gas people contend, do not justify any maker of carbon-filament lamps in saying he can give 12 lamps of 16 candles each to the electrical horse power." Of all interested in the matter the gas companies should not be amongst the first to throw stones. It is a well-known fact that no gas company does furnish the candle power claimed per cubic foot of gas, and to find out how near these companies come to their claims, the writer made some tests of which the accompanying diagram and tables show the results. There is practically nothing new in the matter.



Pressure 1¾ inches Time 8.30 to 11.30 A.M. August 13th 1892.

FIG. 1.

TABLE I.

Burner tip feet.	Candles.	Gas per hour. Cubic feet.	Candles per foot.
2	5.75	5.53	1.03
3	9.8	5.5	1.78
4	11.1	5.	2.2
6	13.	5.5	2.36
7	13.3	5.18	2.56

The diagram Fig. 1, includes the price of gas at the rate of $1.50 and $1.75 per 1,000 cubic feet. The burners were of the common kind most generally in use, and the time, 8.30 to 11.30 a. m., was selected because, on account of the lower pressure, it must be more favorable for the gas interests. The tests in Table I. were made with the "Champion" regulating burner which is indorsed by the gas people. The burner was regulated for 5 feet of gas, but 2, 3, 4, 6 and 7 feet tips were used with it. The benefits of this burner are claimed to be reduced gas bills and complete combustion of the gas. As the burner is regulated for a certain maximum flow of gas per hour the gas bills should certainly be smaller than without the regulating device; as to the amount of light produced per cubic foot of gas the reader may judge for himself. The gas pressure outside of the regulating burner was $2\frac{3}{16}$ inches and the time 8 to 10 p. m.

Table II. shows the ordinary burner with the gas at the same pressure. We find that the conditions are not improved to any extent by the use of regulators. The best results give us 2½ candles per cubic foot of gas, while the gas companies claim $3\frac{8}{10}$. The tests may be criticised from a scientific point of view, but they show exactly the state of things at the consumer's end of the gas pipe.

TABLE II.

Burner tip feet.	Candles.	Gas per hour. Cubic feet.	Candles per foot.
2	11	10.9	1.
3	16	10.6	1.5
4	18	10.4	1.74
6	28	14.6	1.92
7	31.25	15.1	2.

Comparing the price of incandescent lights with gas, candle for candle, we find it about even at $1.75 per 1,000 feet of gas on the one side and 1 cent per 50 watt hours (the usual charge) on the other. The light from a 50-volt lamp of 55 watts will cost the consumer 1 cent per 14½ candles, while from a 100-volt lamp of 60 watts it will cost 1 cent for 13¼ candles. If less efficient lamps are used, the consumer of course has to pay more for his light, and this leads us to the question of efficiency.

When the consumer puts in the electric light he expects more light for less money than he paid for gas; in rare cases he puts it in as a matter of luxury and even where this happens it will be a question of dollars and cents in the end. Therefore lamps of high efficiency should be used; such lamps however can only be run satisfactorily where great care is taken to keep the voltage constant. Whenever an investigation is made on a complaint of lamps not lasting long enough, it will be found that they are run above voltage.

It must be admitted that a lamp of four watts per candle will stand the variations better than one of three and one-half watts, but to compete successfully with the old-established gas-light, in regard to price, the more efficient lamp should be used, and the consumer who pays by the meter will find it the cheapest in the end, even if it should burn out after 300 hours' use, while station managers where light is furnished by contract, will find their coal bills reduced. At the rate of one cent per 50-watt hours the consumer pays at the end of 300 hours $3.30 if he is using a 55-watt lamp; using a 60-watt lamp he pays $3.60 for current, and $3.90 if his lamp should take 65 watts (4.1 per candle). Thus, enough is saved every 300 hours to pay for a new lamp. But the prospects are that as long as only the life of a lamp is considered, the efficient lamp will not find many friends. There are still too many who point with pride at the lamp that burned 5,000 hours, though it only gives about three candles. Lamps that have been in use 1,000 hours drop 50 per cent. in candle power, as has been shown by Prof. Thomas, and to obtain satisfactory illumination, and, considering the present low price of lamps, should be replaced by new ones when they drop below 12 candles.

This loss of candle power and the blackening of the lamps have been variously explained from time to time, but we are still in the dark. The latest theory is the presence of mercurial vapors in the lamps which are utilized by carbon particles as a medium of transportation to be safely landed on the inner walls of the bulbs. What become of the carbon particles in lamps which contain no traces of mercurial vapors is not made clear; like good carbon particles, they probably stay at home. Neither has it been explained why some lamps exhausted by means of a metallic pump blacken in spite of the absence of mercurial vapors. Experiments made in this direction show that filaments surrounded by mercury vapors will turn black and drop in candle power while the bulbs remain clear.

Supposing the heat given off by the filaments during the burning process should aid the volatilization of the mercury in the pumps, could the vapors, in the very short time the mercury is at its highest point, reach the lamps? Mercury vapors may rise to a height of over 36 inches while the distance between the check valve of the ordinary Geissler pump and the top of the fork is somewhat less than 30 inches; but as the mercury is constantly in motion it is hardly possible that the vapors would rise to their greatest height. If there are such vapors, their effect would be in the pump only, but no trace would be found in the lamps. The effect on the lamps, however, might be indirect.

If one will take the trouble to inspect burned-out lamps in quantities, collected from different places, he will find that the larger the candle power, the greater the blackening; this is especially the case with lamps made by two of the oldest companies. In many cases 50 c. p. lamps are discontinued on account of excessive blackening. Now, why do the high candle power lamps blacken more than the others? The filaments are usually made the same way, and the lamps treated the same way on the pumps.

Supposing we accept the mercurial vapor theory in part; we might then account for the blackening in this way: When the lamps on the pumps are sufficiently exhausted and the current is turned on, the gases contained in the filament are set free. At the start these gases are readily taken off by the pumps, but as the process progresses the amount of gas diminishes while the heat increases and causes mercury vapors to rise; then these vapors, though only a short distance above the body of mercury, may rise sufficiently to prevent the lighter gases from the filaments from escaping through the pump. Thus we may have a residue of gases on the one side and a perfectly empty pump on the other. On cooling off, these gases will be absorbed again by the filament, and when the lamp is opened under mercury it will show as near a perfect vacuum as may be obtained with any pump, mercurial or metallic. But in the course of time these residual gases, by the action of the current, will increase, if not cause, the gradual disintegration of the filament and in this way blacken the bulb. The large outlet in the metallic pump may take the gases off more readily than the mercurial pump, but the oil vapors throughout the system of piping may also prevent the lighter gases from escaping; if not, why is it that some of the lamps exhausted with a metallic pump do blacken? As the blackening is undoubtedly one of the consequences of the natural disintegration of the filament, and the residual gases are one of the causes, the writer has modified the ordinary Geissler pump in such a way as to have a continuous suction and thus not only shorten the time but take the gases off more readily and also prevent possible mercurial vapors from rising. Lamps exhausted with this pump show very little blackening after 500 hours' use.

The blackening of lamps will probably never be satisfactorily explained, but it is a problem worth studying, and lamp makers should do all in their power to reduce it as much as possible. If it can be proven that the lamps exhausted with the metallic pump do not blacken while all others do, then let us discard the mercury pumps; until then, however, we had better remain true to this old friend, whose advantages, thus far, outweigh the disadvantages of the other.

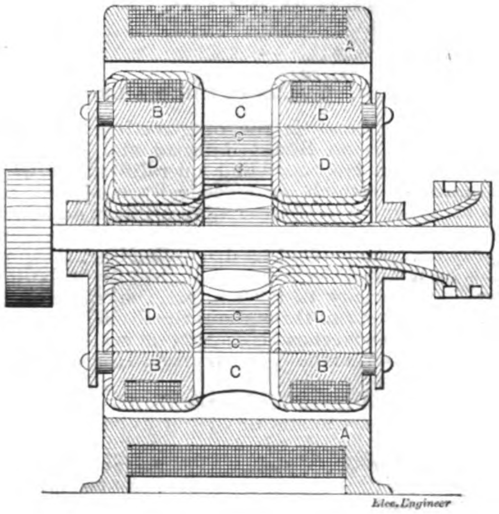
ON A NOVEL TYPE OF UNIPOLAR MACHINE.

BY

Wm A. Carey

I HAVE read with interest the several articles in THE ELECTRICAL ENGINEER on the unipolar dynamo, and would like to contribute a trifle on the subject.

Mr. Balch has mentioned two characteristics of the so-called unipolar dynamo, which are undoubtedly worth considerable study and experiment (uniformity of direction and strength of current) inasmuch as, judging from analogy, hysteresis and self-induction would probably not obtain to any appreciable extent if the current action could be maintained at normal without fluctuation or change of sign. Mr. Balch also says that the main difficulty with the type of machine shown by him is, that the conductor cannot be coiled, which, of course, would be necessary to raise the potential. But I believe it probable that the winding and proper movement of conductor can be accomplished in a differently designed apparatus. I say movement, because Mr. Balch actually obtains no movement whatever, either of conductor or field of force, as Mr. Steinmetz very clearly demonstrates in the ENGINEER of October 5, and a rotation of the magnet does not carry the magnetic field with it; consequently no change takes place in the relative position of conductor and lines of force.



THE CAREY UNIPOLAR MACHINE.

Mr. Steinmetz states that no E. M. F. exists in the conductor W, but is limited to the "inside conductor, the magnet M S itself." It would seem, however, that the electric current implied by the observed E. M. F. must complete its circuit through the conductor to be observed at all, or, in fact, to exist. Faraday is clear in his description of the experiment in question, and the machines of Forbes and Delafield produced large currents, but no attempt to realize high voltage has succeeded under this method of induction, as far as I can learn.

As the machines mentioned actually gave a large output of energy and manifestly moved their conductors in a uniform field of force, is it not possible that the difference of magnetic intensity between the two points of contact of the conductor with the magnet (at the pole and at the neutral point) may offer a promising field for exploration?

When a description of Forbes' dynamo first appeared about six years ago, the writer, with a desire to control the factor of E. M. F. in a machine designed on the same lines, worked out the details below, which are submitted to such of your readers as have given thought to this interesting phase of inductive effect. I have never had an opportunity to demonstrate this idea practically, but have talked it over a good deal with able experimenters, including Mr. Tesla, without discovering any reason why it should not accomplish its purpose.

Reference to the accompanying sketch will show Faraday's experiment carried out as far as moving a wire in a horizontal plane through the lines of force between maximum and minimum magnetic strength is concerned. It is clear that if the wire is wound close to the iron of the armature, both inside and outside of the ring, the current would be generated in the same direction on each side, and thus would neutralize itself; but if the inside portion of the coil is carried away towards the centre of the armature, there would be a differential effect in one direction, the strength of which would, without doubt, be proportional to the square of the distance between the iron ring and the inner side of the helix. The amount of resistance or length and size of wire necessary for a given E. M. F. would probably be governed by the same formulæ as in ordinary armatures, with perhaps some modification on account of the influence of the distant ring. The magnetic lines would, however, be well contracted between armature and field.

The following explanation will make clear the details of construction:

A is an annular magnet, wound simply to render the whole of each side of an opposite polarity. B is also an annular magnet so wound as to give opposite polarity from that of the field. This armature is in reality two rings joined together with spokes of iron, cast with the rings, so that the wire may be wound in opposite directions on each half and still possess only two poles; the wire may be wound on one-half of the armature until full, and then merely carried across and wound on the other half, bringing the two ends to a collector.

C C are the iron spokes or connections. D is a non-magnetic material, such as wood, etc., which is used so that the inner wire shall not be subject to magnetism. No supports for the shaft and armature are shown.

Will this machine generate a current, and if so, will there be the usual phenomena of hysteresis and self-induction? Would the absence of these two factors compensate for the large amount of dead wire involved in this design and show fair efficiency?

ELECTRIC RAILWAY DEPARTMENT.

THE BINGHAMTON, N. Y., ELECTRIC RAILROAD COMPANY.

THIS interesting road is the outgrowth of the consolidation of the Binghamton Street Railroad and the Binghamton and Port Dickinson Railroad, and operates about 22 miles of road, 10 miles of which is electrically equipped while the other 12 is at present operated by horses. It is now proposed to equip the entire road with electricity and bonds are being issued for that purpose. An acre of land on the river, in the heart of the city has been purchased, upon which will be built a power house having a capacity of 1,400 h. p. The tracks are being relaid with 72 lb. girder rail throughout the town and 48 lb. tee rail in the suburbs. The overhead construction is also under way and contracts have been made for Thomson-Houston motors and Stephenson cars.

Three and one-half miles of the Binghamton Street Railroad, operated before the consolidation by horses, has since been equipped with electricity an affords and interesting example of the relative merits of the two systems. The earnings shown for this section, using three cars drawn by horses, from Oct. 13 to Nov. 9, 1891 were $538.55, while from Oct. 13 to Nov. 9, 1892, electrically operated, the earnings were $1,264.80. A comparative table, showing the earnings under the same conditions and with the same number of cars, for the first two weeks operated by horses and the last two weeks by electricity shows:

Sept. 29 to Oct. 13, 1892, horses	$322.60.
Oct. 13 to Oct. 26, 1892, electricity	680.30.

Mr. W. J. Clark, expert and general agent of the railway department of the General Electric Company, has submitted an exhaustive report upon the road from which it appears that the average gain in earnings for the year 1891 over 1890 was more than 33⅓ per cent.

The officers of the company are G. T. Rogers, president; John Evans, first vice-president; Hon. J. B. Landfield, second vice-president; C. O. Root, secretary; J. B. Rogers, treasurer; J. P. E. Clark, manager, and S. E. Monroe, engineer.

THE PASADENA AND SIERRA MADRE RAILWAY.

ONE of the most comprehensive systems of mountain railway in the world is contemplated by capitalists at Pasadena, Cal.; namely, the building of a railway, part cable and part trolley, from Altadena, the last station of the Los Angeles Terminal Railway Company's lines, to the summit of Mount Wilson. Hourly communication will then be afforded between the highest peaks of the Sierra Madre and the coast, thirty miles distant.

The first portion of the mountain road proper will be erected against the southern flank of the most conspicuous promontory of the entire Sierra Madre Range, starting from the base of Rubio Cañon. This will consist of a double-tracked cable road, with balanced cars and safety appliances, and will be operated with a stationary electric motor, power being furnished by a neighboring waterfall. This cable will be superior in strength and capacity to those used on Mt. Vesuvius, the Island of Hong Kong and the Lookout Mountain, in Tennessee. From this point the second division of the road takes its start. The surveys for this have disclosed a line of less than seven per cent. grade along natural ridges and curves clear to the highest summit desired. This grade admits of the construction, immediately below the crests and in the face of the range itself, of about six miles of road. These will be operated by electrical power, and supplied with Pullman double decked cars. The first section, it is expected, will be completed by the early autumn while the construction of the second, or Electrical Mountain Railroad division to the summit, will follow the completion of the cable without delay.

From comparison with the mountain railways already constructed both in this country and abroad, Prof. T. S. C. Lowe, of Pasadena, the originator and prime mover in the enterprise, anticipates a large and profitable business.

The latest official returns from the Mt. Rigi R. R., Switzerland, for instance, give a total net receipt of $100,000. It carried one hundred and twenty-nine thousand five hundred and forty-three passengers and conveyed four hundred and fifty tons of passenger baggage, and one thousand two hundred and fifty tons of other goods. Over four hundred thousand passengers are annually carried between Pasadena and Los Angeles.

The road is capitalized at $600,000.

THE GARTON LIGHTNING ARRESTER FOR ELECTRIC RAILWAYS, ETC.

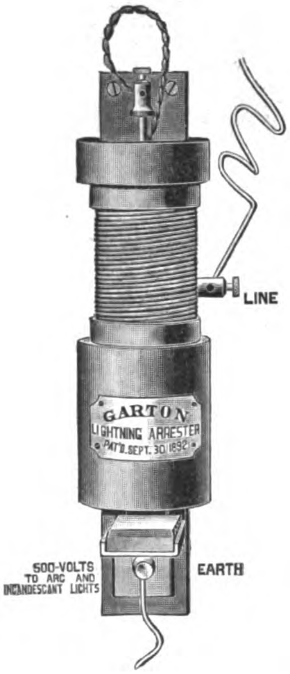
A RELIABLE lightning arrester is now recognized to be an indispensable adjunct to all electric railway and power circuits, etc., and hence a simple device of this character which has given good results in actual practice will be of interest to station managers.

The Garton lightning arrester which is illustrated in the accompanying engraving consists of a coil of wire wound upon a spool of non-conbustible material. Below this coil is an air chamber of the same material as the spool and forming a part of it. In this air chamber and resting upon a carbon plate which forms the bottom of the air chamber, is an armature fastened to a guide-rod which is made of non-magnetic material, but is a good conductor for the passage of the discharge. The centre of the coil being hollow, the armature and guide-rod can rise and fall the full length of the coil.

The guide is fastened to a flexible conductor (by means of a binding post which is a part of the guide-rod) which goes to the inside end of the coil; and the outer end of the coil terminates in a binding post, which may be attached to the line wire. At the lower end and just beneath the air chamber is another carbon plate with a serrated surface toward the first carbon, forming the bottom of the air chamber.' This lower carbon plate may be adjusted at any desired distance from the upper plate, thus at will varying the air space, as may be desired. This carbon plate is held in place by means of a bracket, to which is attached a binding post to which the ground wire is connected. Thus when a static discharge takes place the lightning enters the binding post, marked "line," thence passes through the coil, the flexible conductor to the armature and guide-rod, through the guide-rod and armature to the carbon plate forming the bottom of the air chamber and upon which the armature is resting, across the air space to the lower carbon plate and into the earth.

The passage of the lightning across the air space produces an arc through which the generator current flows to the ground, forming a dead short circuit. The flow of current through the coil energizes the coil which instantly draws the armature into it, thus raising the armature from its contact with the top carbon in the chamber and establishing an arc in the air chamber. The air chamber being closed at the top by the rising armature and the oxygen in the air chamber being consumed, the arc is destroyed, and the current ceases to flow. The coil being thus deprived of its energy, the armature again falls of its own weight to its resting place in readiness for another discharge, the whole process occupying a fraction of a second.

It might be thought that the coil offers some resistance to the passage of the lightning, due to its self-induction, but it is claimed not to offer any more than a straight conductor of the same cross section and length, for the reason that the core or armature is not inside the winding until after the passage of the lightning. It will be noted that the construction here adapted involves no pivots or hinges and as a matter of fact the arrester requires no attention, whatever, resetting itself automatically after each discharge. Each one is thoroughly tested by Leyden jar discharge before being sent out.



THE GARTON LIGHTNING ARRESTER.

These arresters which are built by the Garton-Daniels Electric Co., of Keokuk, Iowa, have been in use for some time on railway and lighting circuits, and are claimed never to have failed to protect in a single instance.

STILLWATER AND MECHANICVILLE, N. Y., STREET RAILWAY.

THE STILLWATER AND MECHANICVILLE STREET RAILWAY COMPANY, have applied to the Secretary of State, for permission to change the motive power of the road from horses to electricity. Work will be commenced as soon as the required permission is granted. The stock and franchise of the road is owned principally by the banking house of D. Powers & Sons, Lansingburgh, under whose management a new company will be formed to construct and operate the electric road. The plans are under way, and it is stated that they include a belt line track over a number of Mechanicville streets, as well as an ultimate extension to Waterford, and possibly a connection at that point with the Troy City Railroad, although the latter plan is at present a very remote contingency.

ELECTRIC CARS FOR SWIFT MAIL TRANSFER.

DISCUSSING the question of mail transfer in large cities, so as to gain time, Postmaster-General Wanamaker says in his forthcoming annual report:—"The great needs of New York, as I have repeatedly pointed out, are a new Post Office building and a pneumatic tube or electrical service. The citizens of the metropolis may have these absolutely necessary facilities whenever Congress votes the money for them, and the pneumatic tube experiment already in progress in Philadelphia will show results, I hope, which will render it safe for Congress to apply the system generally to large cities, for there can be no adequate postal service in such immense and growing population centres as New York, Chicago, and Philadelphia, and perhaps in places like St. Louis and Boston also, until the tubular or electric post is made use of. I have never tired of pressing this need, and if Congress should not meet it I hope the great cities will continue the agitation. However much the Postmaster-General is called to account, he cannot give these facilities until Congress says so and makes appropriations."

BIDWELL ELECTRIC RAILWAY LITIGATION.

A DISPATCH from Toledo, O., of Dec. 3, says:

"Suits were brought here to-day involving every electric street railway in the United States. Two suits were filed in the United States Circuit Court by the Hon. Frank H. Hurd and O. S. Brumback, attorneys representing Benson Bidwell of Rochester, Ind., against the Toledo Consolidated Street Railway. It is claimed that this company has infringed Bidwell's fundamental original patents for running electric cars and the principle involved in the use of underside spring contact; also, that the patents for the running and lighting of cars with the same current of electricity and the lighting of streets and houses along the line from the current which propels the cars have been infringed upon.

Charles F. Bidwell of this city is interested in the patents of his father, Benson Bidwell, and has been working for the past three years with a view to bringing suit against the street railway companies which, he claims, have been infringing upon them. The Consolidated is to be a test suit.

Mr. Charles Bidwell claims that the prospect for winning the suit is good, inasmuch as the attorneys, Messrs. Hurd & Brumback, have been investigating their claims for over two years, and have now decided to commence the fight.

The two suits filed, one for the lighting, the other for the underside trolley patent, are in the name of Benson Bidwell, Trustee, but back of him is a long list of parties interested, including C. F. Bidwell of Rochester, Ind., Charles F. Bidwell of Toledo, the Hon. Frank H. Hurd of Toledo, O. S. Brumback and Jennie C. Brumback of Toledo, the Fidelity Safe Deposit and Trust Company of Philadelphia, executors of the William Howells estate, William Rosengarten of Philadelphia, and others."

Some of our readers may remember the Bidwell electric railway exhibit about 100 feet of track, with one car, made at the Philadelphia Electrical Exhibition in 1884. Mr. Benson Bidwell was in charge of the exhibit, which was in the annex.

NEW ORLEANS, LA.—The deal by which the New Orleans City & Lake and the Crescent City Street Railways pass into the hands of Northern parties has been effected. The new owners will organize with Jesse Seligman, of New York city, as president, and Maurice J. Hart, of New Orleans, general manager. It is intended to equip all the lines with electricity.

MT. VERNON, N. Y.—The common council of this city, has set aside the veto of Mayor Brush and conferred upon the Westchester Electric Railway the right to begin the erection of its line through the city, over a route previously designated.

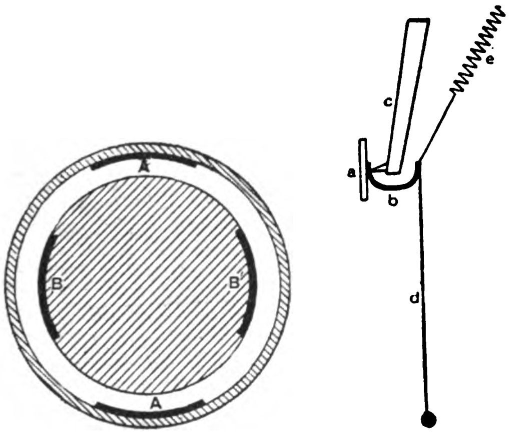
MISCELLANEOUS.

THE EWING MAGNETIC CURVE-TRACER.[1]

AT a meeting of the Cavendish Physical Society, Cambridge, Prof. Ewing gave an exhibition of his magnetic curve-tracer, using a form of the instrument which has just been constructed by Messrs. Nalder Bros., of London, with the object of allowing the magnetic cycle to be performed at a high speed. The instrument is shown in Fig. 1, which is engraved from a photograph. The magnetic circuit, whose variations of magnetism are exhibited, is arranged as a rectangle standing up from the base plate, and supported by a post in the centre. It is laminated, consisting of a number of strips of thin sheet iron, of the kind used in transformer cores. The ends of these are securely clamped in a pair of wrought-iron pole-pieces on the base plate, which is a slab of slate, and the poles have a narrow gap between them within which the stretched wire works which gives vertical motion to the mirror, proportional to the varying magnetism of the laminated circuit. A gun-metal casting, arranged in the form of a bridge, supports the compound lever by which the pivot of the mirror is supported, as well as the springs which serve to keep the connecting threads taut; and the same bridge piece forms a post for the support of the main magnet, and also carries the other electromagnet, which consists of a piece of iron tube split longitudinally to form a slot for a second stretched wire, which gives horizontal deflection to the mirror proportional to the magnetizing force. This result is secured by keeping the magnetization of the tubular magnet constant, and by allowing the current which circulates in the magnetizing coil of the main magnetic circuit to pass through the wire that is stretched in the slot of the tubular magnet. The pivot-point of the mirror is held by a system of two adjusting levers which are moved by milled-headed screws to give it two adjustments, vertical and horizontal, for the purpose of bringing the zero position of the spot of light to any desired point of the screen. The mirror itself is pivoted in the manner shown in Fig. 3. The mirror *a* is cemented to a little cradle *b* of aluminium, in which a small hole or rather recess, is drilled just behind the mirror. Into this recess a needle point, held by the fixed piece *c*, enters. At the other side of the cradle two threads are attached, of which one, *d*, goes down to the vertically-moving wire in the gap of the variable magnetic circuit, and the other comes out, perpendicular to the plane of the paper, to the horizontally moving wire in the gap of the constant magnetic circuit. A pair of light spiral springs, of which one is indicated in the sketch at *e*, hold the threads taut and are set to rake back a little, so that they give a component of force pressing the mirror cradle against its pivot sufficiently to prevent it from slipping off.

---

[1] London *Electrician*.



FIGS. 2 AND 3.

The magnetic cycle is performed in one-tenth of a second or less, but so smoothly that the mirror is at no stage subjected to any jerk. This requires that the variations of magnetizing current shall be continuous and gradual. An ordinary commutator with sudden makes and breaks of contact will not do, and the necessary smoothness is obtained by using a continuous commutator, the joint invention of Prof. Ewing and Mr. C. G. Lamb, which was described at the Cavendish Physical Society for the first time. The principle of the continuous commutator will be seen by reference to Fig. 2, which gives a sectional plan of the essential parts of the instrument. A cylindrical vessel of glass or earthenware, containing a solution of sulphate of zinc, has two zinc plates, A and A', fixed in it at diametrically opposite portions of the inner circumference. These plates are connected respectively to the two poles of a battery. A boss of non-conducting material nearly fills the vessel, leaving only a narrow clearance space round it for the sulphate solution. The boss is supported on a footstep; which allows it freedom to revolve, and is turned either by hand or by a pulley at the top connected with an electric motor. A second pair of zinc plates, B and B', are fixed to the boss itself, on opposite sides of its circumference. As the boss revolves the plates fixed on it take a potential difference approximating to that of the fixed plates, as they pass these; then a quarter revolution brings the potential difference gradually to zero, the next quarter revolution raises it gradually to a value equal and opposite to the first, and so on. The plates carried by the boss are connected to collecting rings on the vertical spindle, from which currents are led off through brushes to the magnetizing coil of the magnetic curve-tracer. By having one of these continuous commutators placed in series with a fluid resistance slide, to superpose a continuous reduction of the strength of the current on periodic changes on its sign, the experiment was shown of "demagnetizing by reversals," in which the curve-tracer exhibited the cyclic process, gradually diminishing its range until the area of the diagram vanished. The "Rayleigh" stage of the magnetization, when a feeble force applied or reversed gives magnetic changes involving no hysteresis, was well shown in this way. A still more striking experiment consisted in placing two of the continuous fluid commutators in series, and turning one slowly or quickly by hand, while the other was left revolving uniformly at a high speed, when small loops appeared superposed on the principal cycle of magnetization.

The main magnet of the instrument, shown in Fig. 1, is wound with two magnetizing coils, which allow experiments to be readily made showing the influence exerted by a permanent magnetization of any assigned value on the behavior of the metal with respect to a supplementary force subject to cyclic variation, and on the amount of hysteresis which such a supplementary cycle involves.

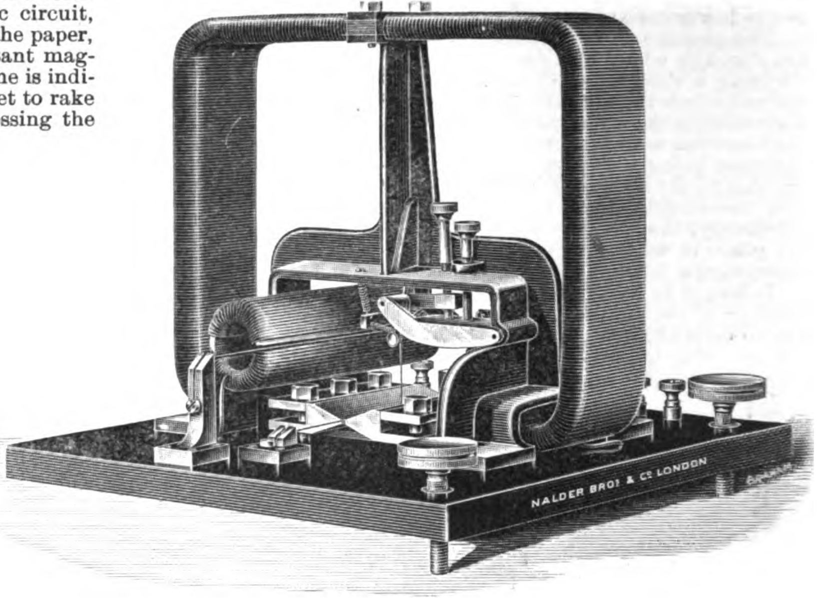


FIG. 1.—EWING'S MAGNETIC CURVE TRACER.

LEONARD'S SYSTEM OF CONTROL FOR ELECTRIC TRAVELING CRANES.

THE Leonard system of control for electric motors differs essentially from other methods by virtue of the fact that the regulation is effected in the electric generator supplying the motor and not in the motor itself. In methods heretofore used the generators produced a constant pressure and were not regulated when a change of speed or of direction of rotation of the motor was desired; but all the regulation was effected at the motor by reversing switches and rheostats in the path of the current supplied to the motor.

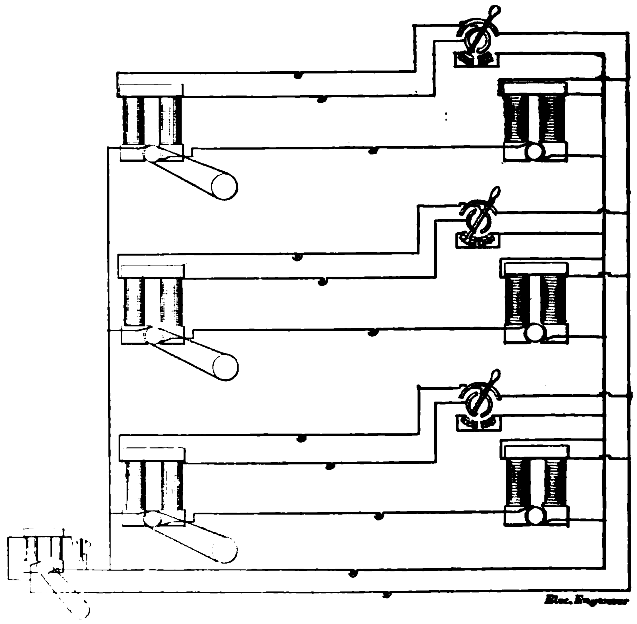

FIG. 1.—THREE MOTOR CRANE, EACH MOTOR CONTROLLED INDEPENDENTLY.

In the Leonard system, when it is desired to reverse the direction of the motor, the magnetism, and, consequently, the current of the generator, is reversed. Similarly, when a lower pressure is desired on the motor, in order to go slower, the pressure produced by the generator is reduced, instead of keeping the pressure of the generator at its full amount and reducing the pressure supplied to the motor by means of a rheostat.

To move a load slowly by the rheostat system requires practically the same power as is required to move it rapidly, the surplus energy not desired being dissipated in the rheostat. In the Leonard system the power required is proportional to the work done in all instances, so that, for instance, to move a load at one-quarter speed requires but one-quarter of the power needed for full speed.

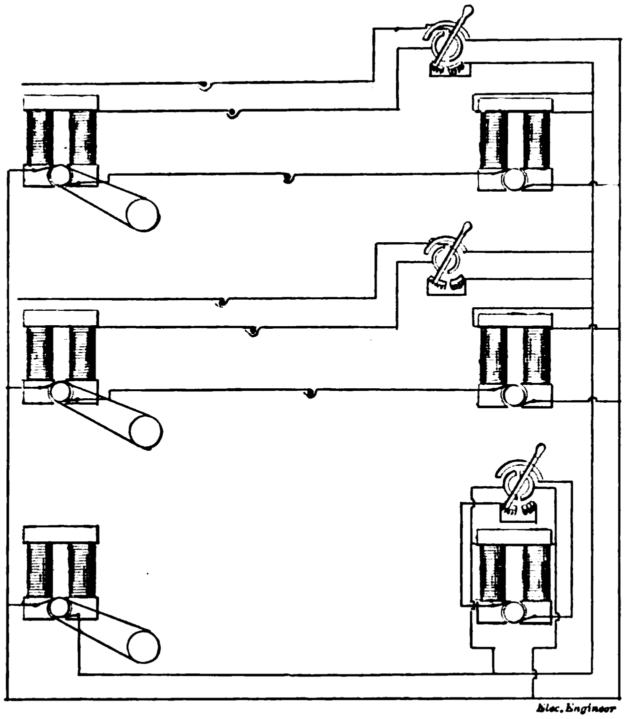

FIG. 2.—THREE-MOTOR CRANE, TWO MOTORS CONTROLLED INDEPENDENTLY.

The control in the Leonard system, it will thus be seen, is effected entirely by varying the strength and direction of the current supplied to the field of the generator. In a well designed generator of moderate size, the current for the field is about 1½ to 2 per cent. of its total output, so that the current varied is extremely small, even in the largest generators, and, consequently, the controller is very small and entirely sparkless.

The accompanying diagrams, Figs. 1 to 4 inclusive, show various modifications of the application of the Leonard system to traveling cranes. No mechanical brake is required in the system, as the retardation of the load is accomplished by causing the motor to become a generator, which feeds back current to the general system, thereby not only bringing the load smoothly and rapidly to rest, but also effecting a marked economy by utilizing energy usually wasted in friction. Both the generator and motor are entirely sparkless under all conditions. This system is applicable to any electric generator and motor made, without any alterations whatever, and has been already applied upon motors of the following makes: Edison, Eddy, C. & C., Elektron, Eickemeyer, Waddell-Entz, Crocker-Wheeler and several others.

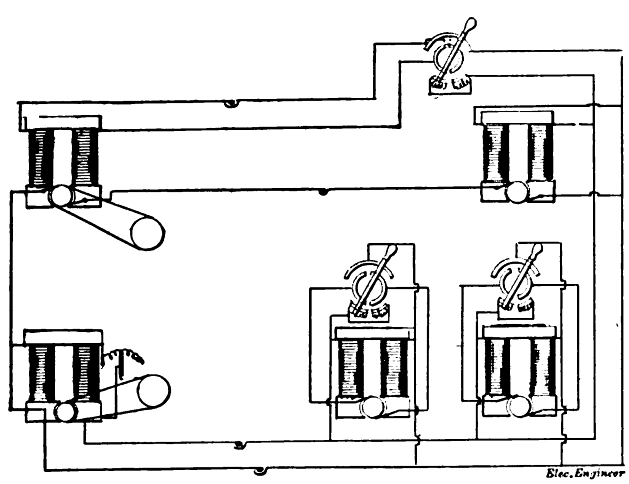

FIG. 3.—THREE MOTOR CRANE, ONE MOTOR CONTROLLED INDEPENDENTLY.

Under the Leonard system the speed of the motor is practically independent of the load. In other words, there is at command an infinite number of automatic speeds in either direction of rotation. It is very surprising to see a motor turning but a few revolutions per minute under only frictional load, and then pick up its full load without slowing down appreciably. Similarly, when running slowly under full load, its speed is not appreciably affected if the entire load be removed instantly. When the motor is running under full load, at full speed, the reversing lever can be thrown over instantly and the load will be quickly and smoothly retarded and then accelerated to full speed in the opposite direction, without the least jar or any sparking whatever.

The system of control is thoroughly protected by patents in this country and abroad. It is of interest to know that licenses have been granted to quite a number of leading manufacturs of hoisting machinery, among them the following: William Sellers & Company, Incorporated, Philadelphia; T. Shriver & Company, New York City; Otis Brothers & Company, New York City; Crane Brothers, Chicago; Hale Elevator Company, Chicago; Whittier Machine Company, Boston; Stokes & Parrish, Philadelphia. Wherever a motor is desired to operate at varying speeds under varying loads, and especially where it is also to be reversed in direction, this system gives excellent results. The perfection of the control in all movements of the load by this system make it of great value in traveling crane practice.

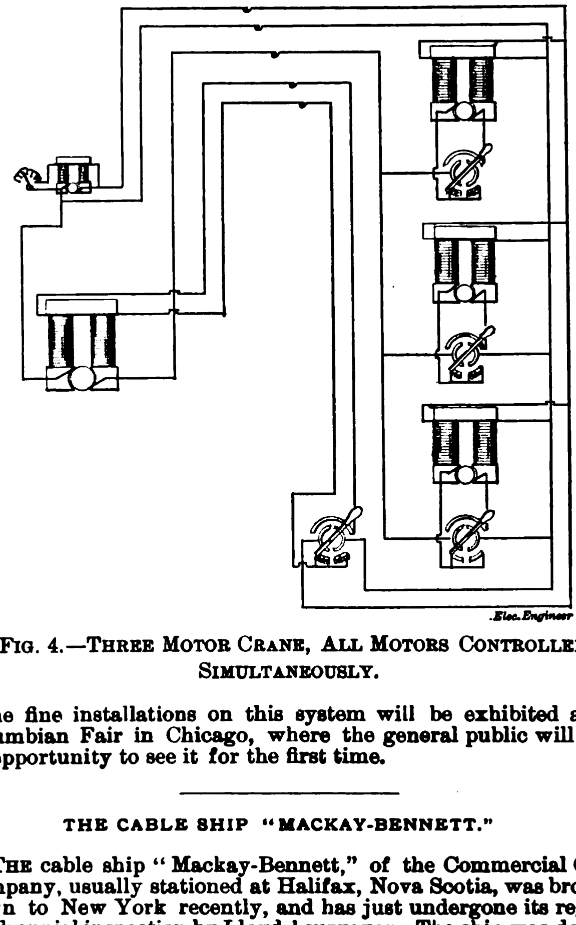

FIG. 4.—THREE MOTOR CRANE, ALL MOTORS CONTROLLED SIMULTANEOUSLY.

Some fine installations on this system will be exhibited at the Columbian Fair in Chicago, where the general public will have an opportunity to see it for the first time.

THE CABLE SHIP "MACKAY-BENNETT."

THE cable ship "Mackay-Bennett," of the Commercial Cable Company, usually stationed at Halifax, Nova Scotia, was brought down to New York recently, and has just undergone its regular quadrennial inspection by Lloyds' surveyor. The ship was docked at the Erie basin, South Brooklyn. At the invitation of the company we were afforded the pleasure of a visit to the ship, under the guidance of Capt. Schenk, its courteous and able commander. The ship is in every way a model one, being equipped with double screw propellers, which fit it specially for the duties for which it is designed, the ship being able to turn on its heel, a great advantage in cable laying and repairing operations.

The deck arrangements for handling and testing cable work are of the most approved type, and the comfort of the officers of the vessel has been amply provided for.

As to the excellent equipment of the ship and the high order of discipline maintained by Capt. Schenk, no better testimony is needed than the report made by the Lloyds surveyor, to the New York Board of Fire Underwriters, which contains the following: "On examining this ship even down to her ballast tank, I have never in all my experience found a vessel in more perfect condition. The discipline prevailing on board is first class, and the Commercial Cable Company is to be congratulated on the possession of such a fine vessel with so able a commander." We can add nothing to this.

ON THE DISSIPATION OF THE ELECTRICAL ENERGY OF THE HERTZ RESONATOR.[1]

BY V. BJERKNES.

In introducing conducting wires of different metals into his resonator Hertz asserted that neither the resistance nor the magnetic properties of the metal involved a sensible change in the length of the secondary spark.[2] We should, therefore, be tempted to conclude that the oscillations are completely independent of the nature of the metal. This independence is, however, only apparent. In my researches I employed a circular resonator having a diameter of 0.40m., and a complete period (double) of 14 x 10^{-8} second. The poles took the shape of vertical parallel discs 0.008m. apart, and 0.08m. in diameter. In the field constituted by the gap between these dics a piece of aluminum foil, forming an angle of 45 degrees with the azimuth of the discs, was suspended by a quartz thread as an electrometer needle. Instead of the secondary spark the deflection of this needle was observed.

In this resonator I employed in succession geometrically identical conducting wires of different metals, and I obtained very different deflections. In the diagram Fig. 1, I give the results obtained with six wires, all of 0.5mm. diameter, but made of copper (Cu), brass (L), nickel (Ni), iron (Fe), German silver (M), and platinum (Pt) respectively. The resistances of the wires are marked as abscissæ, and the ordinates show the deflections of the electrometer needle.

The results given in this figure appear at first glance singularly opposed to those obtained by Hertz. I think, however, that this divergence is only due to the difference of the methods. The oscillations of the resonator commence at zero and rapidly tend to a maximum, and gradually decrease afterwards. By the spark we evidently measure the height of this maximum; by the electrometer we measure the sum of all the oscillations.

Owing to damping, this sum may have very different values without materially altering the height of the maximum. Consequently, the observations of Hertz show that the resonator always receives the same amount of electrical energy; the electromagnetic measurements show that this energy is dissipated more or less quickly, according to the nature of the metal.

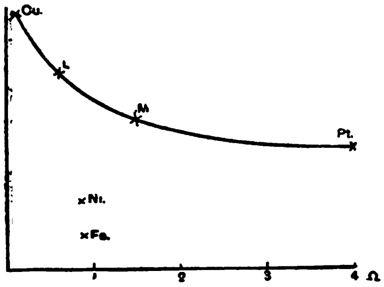

FIG. 1.

The capital point is thus the dissipation. The laws which govern it are represented indirectly by the diagram; a small ordinate corresponding to a rapid dissipation. It will be seen that the four non-magnetic metals ranged themselves on a curve having uniformly decreasing ordinates. On the other hand, the two magnetic metals, that is to say iron and nickel, are quite outside the curve, and the most magnetic metal is that which is the furthest from the curve. I have, therefore, come to the following conclusion: – *The rapidity with which the electrical energy of the resonator is dissipated is increased by the resistance and the magnetism of the conducting wire.* This dissipation may take place in two different ways, by radiation across the dielectric medium, or by transformation into heat in the conducting wire. The considerable influence possessed by the physical constants of the metals seems to indicate that the transformation into heat is the principal cause. This transformation takes place in the thin superficial layer along which the electric currents flow. I endeavored to determine the thickness of this layer with a view of getting to the bottom of the question.

To ascertain this, I covered the iron wire with thicker and thicker electrolytic layers of copper, and I found that the deflections of the electrometer increased, approaching asymptotically to the value of the deflections which took place in the case of the solid copper wire; the difference between the wires disappeared when the layer had a thickness of 0.01mm. I next covered the copper wire with electrolytic layers of iron; even a layer 0.0002mm. thick had an appreciable effect. The deflections very quickly approached the value which they had in the case of the solid iron wire, and all difference disappeared at the moment when the layer exceeded 0.003mm. in thickness. *I conclude, therefore that the currents penetrate less deeply into the magnetic metals than into the non-magnetic metals.*

This result explains the part played by magnetism in the dissipation of electrical energy. The currents being confined to a thin layer, these would encounter a greater resistance, and consequently there would be a greater generation of heat. This explanation agrees with the theory already put forward by Lord Rayleigh and Herr Stefan. I may remark in conclusion that the penetration of alternating currents into the metals is a phenomenon of the same nature as the penetration of light into them. The results which I have obtained are sufficient to prove that metals are more transparent to luminous undulations, which agrees perfectly with theory.

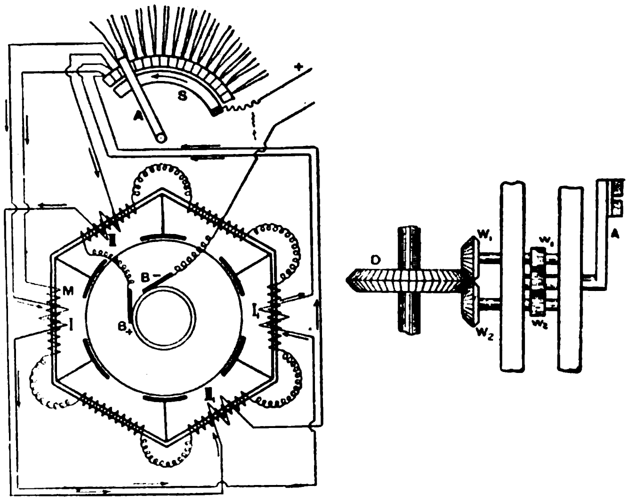
THE GENOA CONTINUOUS CURRENT TRANSFORMER.[1]

Mention has already been made in these columns of the 6,000 volt continuous current transmission plant installed by MM. Cuenod Sautter, of Geneva, for the purpose of supplying power to the dynamos of the Société Genoise d'Electricité, and to other concerns. The following additional details are of interest:

Power is derived from the Ferrari-Galliera aqueduct at a point some 16 miles from Genoa. Three turbines each drive two separately excited Thury 1,000 volt 45-ampere dynamos; the speed of the turbines and the current of the machines being automatically kept constant. The line, which is of bare wire, is carried on oil insulators, and runs underground on entering the town.

At Genoa the current is fed into three Thury motors belted to a countershaft from which four low pressure machines are run. These dynamos supply current to a three-wire 230 volt system. As the two-pressure machines are of the ordinary constant potential constant-speed type, the constant-current motors have to be kept running at a rigorously constant speed whatever the load, and this is effected by an automatic regulator acting on the field excitation of the motors.

The main excitation of the motors is supplied by a large number of series coils in the usual way. The additional excitation required as the motor load is increased is furnished by pairs of coils arranged on diametrically opposite pole-pieces. The + and — ends of these coils are connected to a regulating switch S, as shown in Fig. 1, the main exciting coil being taken to the left-hand segment. The current from the line comes to the strip S, passes across the revolving arm A to the additional excitation coil I, thence to I_1, back to the switch, thence through the additional coils II and II_1, again back to the switch, and thence through the main coils M to the brush B +, through the armature to line by the brush B —. The revolving arm A is rotated by the motions of a centrifugal governor. A toothed disc D, Fig. 2, formed by the juxtaposition of two truncated cones, is placed on the same shaft as the governor balls. Above and below this disc are two mitre wheels, W_1 and W_2, having on their axes the pinions w_1 and w_2, gearing with a toothed wheel, which transmits its motion by an endless screw (not shown) to the revolving arm A. When the speed is normal the disc D is in contact neither with W_1 nor with W_2; but as soon as it increases above or falls below the normal, the disc engages with one or the other of the mitre wheels, and the arm A is suitably rotated.



FIGS. 1 AND 2.

By its arrangement with the Société de l'Aqueduc Ferrari-Galliera, the Société Génoise d'Électricité has to pay a fixed charge

---

L' *Electricien.*

of 300 francs per horse power per year demanded, so that it is obviously to the advantage of the electric light company both to keep down the maximum amount it has to demand and to make the maximum use of the amount actually demanded. Secondary batteries are, therefore, made considerable use of in Genoa, and in order that the dynamos may be able to supply the mains at the same time as they are charging the cells, the battery voltage of 310 to 320 volts is kept down to the proper amount by a compensating dynamo placed in series, its field being regulated as required. The ordinary regulation of the voltage of the cells is carried out automatically by means of electromagnetic devices for switching cells in and out.

LETTERS TO THE EDITOR.

EFFICIENCY OF ALTERNATING PLANTS.

I DO not profess to be an electrical engineer. I am only an ordinary engineer; that is to say, I think I understand how to set up and run a stationary steam engine and boiler, and to get pretty fair work out of it; I have learned enough of electrical matters to be able to manage an incandescent lighting system without any serious breakdowns, and apparently to the satisfaction of the consumers. I regret to say, however, that the owners of the plant are not nearly so well satisfied as the consumers, and hence arises a predicament from which I appeal to you for the means of extrication.

When I took charge of this plant, the outfit consisted of one 750-light alternating dynamo and exciter, one horizontal steam engine rated at 75 h. p., one pair of mains half a mile or so in length, and some 600 lamps wired on about 50 transformers. The parties who installed the plant stated, although they did not apparently guarantee, that every 20 lamps of 16 c. p. each, when lighted, would take one ampere of current on the station ammeter, at a pressure of 1,100 volts. When I took charge, I found that the plant was not doing nearly so well as this, but being unable to discover any serious defect, and being also somewhat distrustful of my own knowledge, I advised having an expert sent for to look things over. He came; he had the coal weighed, superintended the firing, calibrated the ammeter and voltmeter, examined this and that, and finally, with a look of incomparable wisdom, announced that the plant was underloaded, and that when the full complement of lamps were connected with the machine, the discrepancies which I had observed between the consumption of coal, the indications of the station instruments, and the results of the house meter readings would probably disappear. I regret to say that experience has shown that they do nothing of the kind.

According to the original assumption, when the dynamo is carrying its maximum load of 750 lamps, we ought to be consuming about 75 h. p. and sending out 80 amperes of current in the primary wires, while at the rate charged (1 cent per lamp hour), the station should then be earning $7.50 per hour, or at the rate of 20 cents per ampere hour.

We have now two pairs of mains, one carrying 1,145 lamps and the other 154 lamps. These are wired on 97 transformers. This month we are running 8 hours per night, and the following extract from the station log-book will show the character and amount of work we are doing. The figures are amperes at 1,100 volts.

	Sunday.	Monday.	Tuesday.	Wednesday.	Thursday.	Friday.	Saturday.
4.30 p. m........	17	22	21	22	20	23	18
5.30 "	23	30	30	31	30	34	29
6.30 "	23	34	34	33	33	35	34
7.30 "	22	35	35	35	36	38	36
8.30 "	22	35	34	36	32	31	32
9.30 "	19	25	24	24	28	24	27
10.30 "	16	18	21	20	21	22	22
11.30 "	12	15	16	15	18	17	16
Total ampere hours	154	214	215	216	218	224	214
Coal consumed....	1,500	1,800	1,750	1,800	1,800	1,850	1,750

Total ampere hours for 1 week, 1,455.
" " 31 days, 6,022.
Total coal (bituminous) consumed in 31 days...21.75 tons.

Theoretical revenue for 31 days ...6,022 x .20 =	$1,204.90
Actual revenue as per house metres...........	725.60
Deficit................	$479.30

Thus it will be seen that although the plant, as heavily loaded as it ought to be (the maximum current being nearly 40 amperes at times, which warms the dynamo considerably), we appear to be getting paid only for something like 60 per cent. of the current we are sending out. Now, where am I to look for the loss? The insulation of the plant is apparently good, the wire is nearly all "Simplex," and none of the wiring is of less gauge than called for by the accepted formulas; most of it, indeed, is larger. Can so large a loss as this be due to inefficiency in the transformers? The owners of the plant think I ought to make it do better. I think so, too; but I should like to hear the experience of some of the other central station men, who are running plants of similar capacity. One electrical engineer of much experience informs me that if I get as much as 17 lamps per ampere I am doing very well, but I cannot do even as well as that. Of course, I know that the work ought to be done with less coal than is being used, but I understand well enough where the trouble is in that particular. I would like a little more light on the electrical branch of the problem.

NOV. 25, 1892.

THE SPRAGUE-PRATT ELECTRIC ELEVATOR.

MR. SPRAGUE'S answer to my suggestion regarding the Sprague-Pratt electric elevator, which appears in your issue of Nov. 30th, to the effect that "with any well constructed machine, free from internal friction, where the duty required of the motor is measured by the work at the hoisting ropes, the motor cannot be stalled," indicates that Mr. Sprague's experience with electric elevators has been more limited than my experience with electric motors. I think I may be credited with having assumed his machine to be well constructed and that he will use a motor which will be of sufficient horse power to perform the required duty. All elevator builders, like builders of other apparatus, claim that their machinery is well constructed, and it is absurd to suppose that a 10 h. p. motor would be installed where 15 h. p. is required. The point I make is that in the Sprague-Pratt elevator there is no protection for the motor in case, for instance, the brake does not release promptly, or a safe weighing more than the motor can lift is placed in the car. These are occurrences which are very likely to happen and which cannot be figured upon when measuring "the work at the hoisting ropes." Certainly they are as likely to happen as the tricks of the "vicious boy," and should be as fully guarded against. The fact that a number of devices for protecting the armature from injury due to the same and similar occurrences have been patented by various manufacturers, all of whom claim their machinery to be "well constructed," is evidence of the need of such a thing.

Mr. Sprague suggests that I may be the spokesman for some one else. I fail, however, to see in what way that question affects the discussion, but will state that I am speaking solely for myself, and with the license given by the publication of his article.

WM. A. ROSENBAUM.

NEW YORK CITY, Dec. 5, 1892.

LITERATURE.

Traité de Télégraphie Sousmarine. By E. Wünschendorff. Paris: Baudry & Co. 555 pp. 7½ x 11 inches. Price, $8.

No progressive electrical engineer can afford to be ignorant of what is being done in the way of cable manufacture in the great centres of electrical industry across the Atlantic. Especially to manufacturers of cables is a knowledge of this character more important than to the general electrician, for the only way to insure having the best methods is to observe and study those employed by others working in the same departments and adopt such as appear to produce better results than our own. The present work gives a very comprehensive description of the processes and machinery used in the manufacture of submarine cables in European factories, together with other valuable information relating to cables, and is a volume which deserves a place in every electrical and scientific library. As the manufacture of the best submarine cables involves the use of what are known as trade secrets, the reader must not expect to find such secrets disclosed in this work; but, excepting that knowledge of the subject which can be acquired only by years of experience in cable factories, he will be well repaid by reading the book and the information he will obtain will give him a very correct idea of submarine cable manufacture.

The author has treated his subject under five general divisions, the first being historical and giving a brief account and description of the principal deep sea cables, with charts showing their location. The second part describes the manufacture of cables, detailing the composition and properties of their different parts and the machinery used in making them. The principal materials used for dielectrics and exterior envelopes are treated of here; also the methods and apparatus used in preparing and applying them. Various mechanical tests of cables and apparatus, for making the same are also described; joints are included in this division. Part III treats of the immersion and repairing of cables. Beginning with the construction and arrangement of ships employed for this purpose, an account is given of the machinery and apparatus used in immersing, grappling, repairing and raising cables, and also that used in sounding and in taking the temperature of the ocean. The use of buoys and descriptions of the same are also treated of. The injuries most likely to occur to cables from anchors, lightning, the teredo, etc., are described, and remedies therefor suggested. In Part IV the various processes of testing cables, locating faults, etc., are given, with the instruments necessary for conducting such tests. Part V is devoted to exploitation, and explains the transmission of signals and apparatus used in the same. If we have a criticism to make it would be that greater prominence might have been given to the employment of electrical tests during the manufacture of cables, especially those by means of the quadrant electrometer.

The book is well written, contains large clear type, and is thoroughly practical. It contains a great variety of useful formulæ and tables, and excellent illustrations are used whenever necessary to a proper understanding of the subjects treated of.

Thirteenth Convention of the National Electric Light Association. Official Report. *James Kempster Printing Co.* New York, 1892. Cloth. 842 pages.

THIS is the latest volume of transactions issued by the National Electric Light Association, and embodies the proceedings at Providence, R. I., in February, 1891. It is a great pity they have not appeared ere this, as the convention was a most successful one and included a great many features of interest and value. Mr. Marsden J. Perry, then president, did not a little to enhance the importance and dignity of the Association, and left a deep impress for good. Much that is contained in this volume is of permanent interest, and we are glad to know that Mr. Porter, the secretary, is now actively engaged in seeing the transactions of the Montreal and Buffalo conventions through the press. He believes, wisely, that not more than three months should elapse between a convention and the issuance of the official report; and he has done much to bring up the rather regrettable arrears in this respect. The printing and binding of the volume are admirable, and we are delighted to note that the Association has adopted a handsome uniform style for its transactions, in cover, typography, etc. We take this opportunity of earnestly recommending our central station friends to join the Association, if they have not already done so.

With Edison At Schenectady, 1892. A volume of photographs compiled and published by W. H. Butler, Schenectady. 50 sheets containing 125 photos. Cloth $6. Seal leather, gilt edges, $10.

WE have received from Mr. W. H. Butler, of Schenectady, N. Y., a very handsome and artistic volume of photographs, bearing the above title. It is a most interesting collection. There is no explanatory text, and in reality none is needed. The photographs—which run about 9 by 11 inches—have been made from subjects and scenes selected with rare judgment, and grouped with the skill and taste of an artist; and one obtains immediately in turning over these pages a very vivid and faithful idea of the daily work at the great Edison Schenectady Works, with their immense variety of electrical product. Not only is the apparatus clearly brought before us in an interesting manner, but the processes are shown in minute detail. The book is of great value if only as indicating methods in vogue at the present time, in one of the largest American electrical factories. To those who have had any connection with the Edison industries the book must have a special attraction and merit, the more because it contains the portraits of Mr. Edison and a number of his lieutenants. The mounting of the photographs, and the binding, are excellent. A copy of the book can be seen in the reception room of THE ELECTRICAL ENGINEER.

Electric Toy Making for Amateurs. By T. O'Connor Sloan. *Illustrated.* New York, *Norman W. Henley & Co.* 138 pages, 5 x 7 inches. Price, $1.00.

Experience has shown that more than one "amateur," as the expression is commonly used, has made valuable contributions to science, and that the line heretofore so sharply drawn between the scientific amateur and the scientist must now be broadened. Indeed, Prof. Schuster in his recent inaugural address before the British Association, went so far even as to designate Faraday as a scientific amateur in electricity, considering the fact that he took up the subject outside of his profession as a chemist. Making simple apparatus or electric toys is one of the surest ways of interesting beginners in any science and of developing amateurs. This is pre-eminently the case in the domain of electricity, and the little work before us will afford ample opportunity for practice. The apparatus covers considerable range in the application of fundamental principles and will serve an excellent purpose in inculcating these in a manner which no amount of book knowledge can replace. The illustrations are very clear and the text is lucid.

Simple Lessons in Drawing, for the Shop. By Orville H. Reynolds. *Debs Publishing Co.* Terre Haute, Indiana, 1892. 88 pp., 4 x 6½ inches.

This little work is well calculated to give the beginner correct ideas as to the manner of putting on paper designs and plans of machinery. The practical shop methods are always kept in mind and clearness is aimed at above everything. The little work ought to be in the hands of every mechanic and inventor.

LEGAL NOTES.

THE EDISON-SAWYER-MAN LAMP CASE—I.

EDISON ELECTRIC LIGHT COMPANY AND EDISON GENERAL ELECTRIC COMPANY *vs* SAWYER-MAN ELECTRIC COMPANY. FINAL HEARING BEFORE THE UNITED STATES CIRCUIT COURT OF APPEALS.

THIS important case came up for argument in the United States Circuit Court of Appeals, before Judges Wallace, Lacombe and Shipman, Dec. 6, on appeal, as agreed by counsel on both sides in Circuit Court, before Judge Lacombe, Nov. 19.

Messrs. Clarence A. Seward, Grosvenor P. Lowrey, Frederick P. Fish and Richard N. Dyer appeared for the complainant, and Messrs. Edmund Wetmore, Elihu Root and Leonard E. Curtis for the defendant.

The appeal was taken by defendant from the order of the Circuit Court granting a preliminary injunction. The injunction, it will be remembered, was issued and then stayed by counsel on both sides pending the appeal. The suit has been pending for a number of years and was revived, under its present title, soon after the decision of the Appellate Court sustaining the Edison Incandescent Lamp Decision.

Before argument was begun MR. H. W. CHAPLIN arose and made application to be heard in behalf of the Mather Electric Company and in behalf of Mr. Allen, United States Attorney for the District of Massachusetts, stating that suits were pending in the United States Circuit Court for Massachusetts by both parties named seeking relief by way of a general and permanent injunction against what is alleged in their petitions to be an illegal combination, under the common law and under the so-called Sherman act and that in one of these actions one of the plaintiffs in the present suit is alleged to be a party. At the threshold of these Massachusetts suits, and at that of the present suit, thought Mr. Chaplin, lay questions as to the existence and legality of a combination which appeared of record in this case. There was on file with the case a notice from the plaintiff in the Mather suit, and a petition by Mr. Frank D. Allen, United States Attorney for Massachusetts, requesting this court to allow counsel to be heard as *amicus curiae* upon the questions which underlie the several suits—which go to the character, legality and existence of a trust. The desire of the petitioners was that they should not practically have their right adjudicated upon in the present case without being heard.

MR. ROOT for the defendant did not wish to show any discourtesy to the United States Attorney from Massachusetts, or to his representative, but as his application sought to support one of the positions which had been taken by the defendant in the assignments of error, he, Mr. Root, wished to say that the request was entirely without concert or assistance on the part of his clients. They were entirely indifferent as to whether the United States Attorney for the District of Massachusetts, or any one else, should act as the *amicus curiae*.

MR. LOWREY, for the complainant, said that they were, of course, exceedingly glad to see any friend of the Court at any time, and they were also glad their friends upon the other side did not intend to be discourteous. Their own notion, however, after reading the petitions, was that they did not exactly know what he was there for; but they suspected that he was an infringer from down East. "At any rate," said Mr. Lowrey, "we have no objection to his being here; and particularly in this great Democratic city we feel that we owe a certain hospitality and welcome to the State that has recently elected my friend Governor Russell; and upon that ground, if no other, we think the gentleman ought to be heard." After some further remarks by counsel and Mr. Chaplin, the Court granted that gentleman permission to file a brief if it should be ready by the close of the case. The argument of the case then proceeded.

MR. CURTIS for the Sawyer-Man Company, went over the history of the case in the lower courts to some extent, and explained the relations of the parties to the suit in its present aspect, particularly the position of the Sawyer-Man Electric Company, as the lamp manufacturing department of the Westinghouse Company, and as the source of supply for the large number of lighting plants operated by dynamos and other machinery supplied by the Westinghouse Company. In common with other counsel, heard later, Mr. Curtis traversed much of the ground gone over in the arguments before the lower courts, as well as in the United States case.

The bill in this case had been filed Oct. 27th, 1892, and on the 29th of Oct. the complainant served notice of preliminary injunction, an injunction which would at once affect the supply of lamps to Westinghouse plants throughout the country aggregating 1,300,000 lights.

The defense in the case, said Mr. Curtis, rested upon three general facts: (1.) The great destruction of capital which would result from granting and enforcing an injunction; (2.) A combination which had been formed by all (or substantially all) of the competitors of the Westinghouse Company under the name of the General Electric Company—and which combination had come into existence since the decision of the court below in the United States case—and the purpose which had been developed on the part of the complainant to refuse absolutely to sell any lamps for the supply of plants which use Westinghouse apparatus or for the supply of plants of anybody outside of the combination. These defenses were entirely independent of any questions as to the validity of the patent or infringement. (Court adjourned for the day).

The hearing was renewed on Wednesday, December 7th, at 10.30 a. m.

Mr. Curtis, continuing his argument, directed attention to the assignments of errors, summarized in the defendant's (appellant's) brief under general points. Briefly they were as follows:

First. "The growth of vested interests of great magnitude as the direct result of gross laches on the part of the complainants and their predecessors in asserting their rights under the patent; the irreparable injury that would result to such vested interests, to the large number of workmen dependent on them and to the public, would be inequitable, especially in view of the complainant's laches."

Second. "The injunction should have been refused because the General Electric Company, the real party in interest, intends to make an inequitable use of it."

Third. "No injunction ought to be granted in this case, because it asked and would operate in aid of an inequitable and illegal combination in restraint of trade tending towards unlawful monopoly contrary to public policy."

Fourth. "The relations of the parties to the suit were such that the complainants are equitably estopped from seeking to enjoin the defendant from making incandescent lamps of the character it is now making."

Fifth. "The injunction should be refused because it is sought in aid of an attempt on the part of the General Electric Company, the real party in interest, to take an inequitable advantage of the contract relations established between one of its constituents, the Thomson-Houston Company, and the defendant and its associates prior to the combination by which the said General Electric Company, was formed."

Sixth. "The injunction, if granted at all, should have been conditioned upon the complainant's agreeing to supply lamps to the defendant or to his customers on reasonable terms."

Seventh. "The injunction should have been stayed until the first of January, in order to enable the defendant's associates and customers to procure lamps not covered by the patent."

Eighth. "The defendant, should, in any event, have been permitted to dispose of the stock of lamps on hand under proper conditions as to accounting and security."

Ninth. "The injunction as granted is too broad, and should, in any event, have been limited to the second claim of the patent."

Mr. Curtis would leave argument upon the third, fourth and fifth points to Mr. Root, who would follow, and would confine himself mainly to the remainder. He elaborated and emphasized the arguments already familiar in the United States case upon the first point. Passing to the second point, Mr. Curtis took it up in connection with the sixth, as they were merely different phases of the same subject. He would restate it as follows: "The injunction should have been refused, because the General Electric Company, the real party in interest, intends to make an unconscionable and inequitable use of it; or such conditions should have been imposed as would prevent any such inequitable and unconscionable use of the injunction." As to the use the complainants, or the General Electric Company, proposed to make of this injunction: In the first place, the complainants, under the direction of the General Electric Company, proposed to refuse to sell lamps, if they get this injunction, for use with any machines except those made by the manufacturers included in their combination. This has been, in a certain way, disputed. He would refer, in the record, to the affidavit of Mr. Westinghouse, stating that he had been led to believe, by the reports from agents and customers of the Westinghouse Company, that the General Electric Company intended to make use of the recent decision of the Court of Appeals in such a way as to obtain, through its control of the Edison lamp patent, a monopoly of all the apparatus used for incandescent lighting (of which the incandescent lamps themselves form but a very small part) by enjoining other manufacturers of incandescent lamps and refusing to sell its lamps except for use with generating plants of its own manufacture; and referred particularly to the specific instance coming under Mr. Westinghouse's own observation in negotiations for the World's Fair lighting contract; during which it appeared that one of the complainants in this suit, and the representatives of the complainants, stated that they would not furnish any lamps for use with the Westinghouse apparatus if the World's Fair chose to award the contract to the Westinghouse Company, and that under the injunction, which they expected to obtain, the Westinghouse Company could not make any lamps for itself. He also referred to Mr. Bannister's affidavit, substantially to the same purport as that of Mr. Westinghouse, and to other affidavits of similar tenor.

The Court (Shipman, J.): Have you got any action, do you know of any action by the executive officers or directors of the complainants in this suit in regard to non-sale?

Mr. Curtis: We do not know, your Honor, directly, except so far as this evidence indicates it.

The Court: They are statements by agents in the pursuit of business.

Mr. Curtis, continuing, referred to circulars of the General Electric Company, issued in advance of the Appellate Court's decision on the lamp case, claiming that an injunction would probably be served against every company using lamps other than those of Thomson-Houston and Edison make. The evidence, it was admitted, was not of a very direct character. It was, however, the best that could be got on the subject in the time at the disposal of the defense, and should be taken in connection with the state of feeling among the central station lighting companies which this litigation had caused. Such users and purchasers of lamps were naturally afraid of taking any action with would bring down upon them the special hostility of the General Company. It was difficult to get information from them. Of course, the defendant had not access to the records of the General Company, or of the complainants, to see what action they had taken. The affidavits, however, indicated a general policy foreshadowed as one to be adopted. After further references to the record of the case, and the citation of authorities, showing that the Courts had frequently refused to grant an injunction because of the unconscionable use which the complainant proposed to make of it, Mr. Curtis said: "We recognize the fact that, this patent having been sustained by this Court with an interpretation so broad as practically to cover all forms of incandescent lamps which are available for use to-day—that the Court having found that this patent was substantially the foundation of a new art—the Court will naturally be loath to adopt any course which would deprive Mr. Edison and his assignees of their just rewards for so meritorious an invention. Recognizing that, however, we say that if the protection of these interests which have grown up in this way, can be effected and at the same time a just and adequate reward can be given to Mr. Edison and his company for this invention, the Court ought to adopt such a course as would bring about that result."

Mr. Root followed Mr. Curtis, for the defendant, and directed his argument to the proposition that the case was not really a controversy regarding the use of incandescent lamps, but that in its essence, and at bottom, it was a contention regarding the use of machinery for generating electricity—machinery of very great value—widely used throughout the country, and made by manufacturers who had invested large amounts of money. The complainants had, by their own conduct, introduced such other elements into the controversy than the infringement of electric light patents that the court was bound, in exercising its discretion, to grant an injunction, if granted at all, upon such terms as would be reasonable in limiting its effect. There were two elements in the conduct of the complainant supporting the defendant's contention. First, the laches, of which Mr. Curtis had spoken, in the assertion of their rights while enormous sums of money were being invested, not only in the manufacture of lamps, but in the production of other electrical machinery, under other patents, equally entitled to protection; machinery which it was for the public interest to have manufactured, in pursuit of the industry of electric lighting which it was for the public benefit to have pursued, and while costly plants for the installation of electric lighting were established throughout the country.

Counsel hoped their Honors would not for a moment think he would come into court to seek to sustain the proposition that the Edison Company should not have an injunction for the reason that they had been guilty of some disconnected offences, or had been acting inequitably towards somebody else, or had been doing something they ought not to have done not bearing on the subject matter of this controversy. His proposition was that the Edison Company had entered into an inequitable and illegal combination with other corporations, and that they were seeking the order of this court in aid of that illegal and inequitable combination, and that they were therefore not entitled to an injunction. They stood upon an entirely different footing from that which they would occupy if they were only seeking to secure their own monopoly under their own patent and that only by order of the court.

At the threshold of the question as to the combination, Mr.

Root would say that of course a patent was a monopoly; but it was no more a monopoly than any other kind of property, such as that of the merchant in his goods, or of the land-owner in his real estate, or the manufacturer in his mill and machinery; monopoly was the essence of property. A number of patents—perhaps competing and non-infringing patents—might be brought under a single control for effecting the monopoly of an industry; and such a combination might be just as much a violation of the laws against restraint of trade as a combination or monopoly in respect to any other kind of property. But the nature of property in patents is such that it is much more liable to be made the subject of illegal combinations than ordinary property. Combinations for monopoly of ordinary products, irrespective of patent laws, are always likely to invite the investment of new capital and enterprise in competition; whereas a monopoly sustained by a number of effective patents cannot easily be broken; the monopoly given by the government excluding competition, making monopoly permanent during the life of the patent. Such a monopoly as this, but for the Westinghouse Company and its business, which the court was asked to destroy, had been created by the combination between the various corporations united in the General Electric Company. It appeared clearly in the papers of the case that until recently there had been competing, under separate and different patents, in the manufacture of electrical machinery, quite a large number of companies. Among them the Brush Electric Light Company, the Sprague Electric Railway Company, the Fort Wayne Electric Company, the Van Depoele Electric Company, the Short Electric Railway Company, the Schuyler Electric Light Company, the Excelsior Electric Company, the Thomson-Houston Electric Company, the Edison Electric Light Company, the Westinghouse Electric & Manufacturing Company and others, all named in the defendant's brief.

After recounting the successive consolidations of interest among these companies, culminating in the formation of the General Electric Company, Mr. Root said that the Court would perceive the effect of the union of interests between the Edison General Electric Company (the complainant), and the Thomson-Houston Company. Their Honors would also perceive that each of the companies brought into the combination maintained its separate corporate organization, conducted its own business, owned its own property, and dealt with the public just as it had done before the combination. It was not the case of the acquisition of property by one person, it was not the case of the creation of a monopoly by acquiring the property, it was merely the case of a combination of interests between people who still kept their property, who still kept their title to it, and who still conducted their business separately. The complainant's counsel said regarding the combination, in their brief:

> "The details and particulars of a certain well-known public agreement and transaction are set out as if they constituted a body of forbidden acts. This paper needs only to be read to see that it is not a contract in restraint of trade, etc. In fact, it relates entirely to the method by which shareholders of certain companies, who were injuring each other seriously by competition, conducted their perfectly lawful and most praiseworthy negotiations for a cessation of useless and destructive hospitality."

This is to say, said Mr. Root, this was not a sale, this was not the transfer of title, but it was a combination between these corporations for the purpose of suppressing, preventing and avoiding competition. By means of this combination the General Electric Company controlled the entire production and sale of electric light and power machinery throughout the United States, except the portion produced by the Westinghouse Company and a fraction of about ten per cent. produced by all others. Counsel submitted that such a combination was a violation of the laws both of the United States and of the State of New York. It was a violation both of the statute and of the common law. Their Honors were familiar with the declarations of the policy of the laws which were contained in the Federal Statutes, and Anti-Trust Act. Counsel was not here to urge the Court to punish these people for a criminal violation of the Sherman Trust Act; he was here to say that such a combination was denounced in equity and in law in both the Federal and State jurisdictions, here and everywhere; and if the Court find that they are seeking to make it an instrument in carrying out their combination and furthering its effects, it will be bound to refuse the injunction.

The Sherman Act of July 2, 1890, said:

> Every contract, combination, in the form of trust or otherwise, or conspiracy, in restraint of trade or commerce among the several States or with foreign nations, is hereby declared to be illegal.
>
> Every person who shall make any such contract or engage in any such combination or conspiracy, shall be deemed guilty of a misdemeanor.
>
> Every person who shall monopolize or attempt to monopolize a combination, or conspire with any person or persons, to monopolize any part of trade or commerce among the several States, or with foreign nations, shall be deemed guilty of a misdemeanor.

The stock corporation law of New York of 1890, (enforced until May, 1892), provided that:

> No stock corporation shall combine with any other corporation for preventing competition.

In the act passed May 18, 1892, it is provided that:

> No stock corporation shall combine with any other corporation or person for the creation of a monopoly or the unlawful restraint of trade for the prevention of competition in any necessary of life.

This very act, under which the General Electric Company was organized, provided that it should not be considered as "for the creation of a monopoly for the unlawful restraint of trade."

SOCIETY AND CLUB NOTES.

AN IMPORTANT MEETING OF ELECTRICAL INSURANCE MEN.

THE second meeting of electrical insurance inspectors and insurance representatives from all parts of the United States and Canada was held last week in this city on Tuesday and Wednesday, at 156 Broadway. There were 26 delegates present, among whom were: C. M. Goddard, New England Insurance Exchange; E. C. North, New England Insurance Exchange; W. A. Anderson, New York Board of Fire Underwriters; A. E. Van Giesen, New York Board of Fire Underwriters; C. E. Bliven, Western Union; A. E. Braddell, Middle Department; Morton E. Eden, Middle Department; F. E. Cabot, Boston Board; J. P. Freeman, District of Columbia; F. M. Griswold, National Board; W. E. Geyer, National Board; E. A. Fitzgerald, Underwriters' Association of New York State; C. L. Hedge, Underwriters' Association of New York State; J. A. E. Hoeveler, Alleghany County, Pa.; A. W. Hadrill, Canadian Fire Underwriters; A. T. Patterson, Canadian Fire Underwriters; W. McDevitt, Philadelphia Fire Underwriters' Association; W. H. Merrill, Jr., Boston Fire Underwriters' Association; C. F. Low, South Eastern Tariff Association; A. B. Smith, Ontario Fire Underwriters; H. M. Wilson, Cleveland Board.

Mr. C. M. Goddard presided, and Mr. F. E. Cabot acted as secretary. The revised insurance rules already under discussion were taken up, discussed seriatim, and adopted with some slight modifications. Copies of the rules will be sent, for comment, to electrical manufacturing companies, to the various associations interested, etc. The rules cover every wire entering a building from outside, of every class and character.

As the result of the good seen to accrue from organized work, the meeting proceeded to the formation, on a permanent basis, of the Underwriters' International Electrical Association, of which officers were elected as follows: Chas. E. Bliven, president; C. M. Goddard, secretary and treasurer.

The executive committee is to consist of a member appointed from each of the Underwriters' Associations.

An electrical committee was appointed for the purpose of adjudicating upon the technical questions that might be raised at any time and for pronouncing upon the value of any improvements in the art of insulation and its appliances or materials. Its members are: Messrs. F. E. Cabot, W. McDevitt, E. A. Fitzgerald, G. P. Low, A. E. Van Giesen and Leloup.

THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

THE 26th meeting of the American Society of Mechanical Engineers was held at the house of the Society, 12 west 31st street, November 29 to December 2 inclusive. Papers were read covering a wide range of subjects of interest to the members, though none of them contained matter having any practical bearing upon electrical subjects not already familiar to the readers of THE ELECTRICAL ENGINEER. Mr. R. C. Carpenter's paper on "Comparative Variation in Economy with Change of Load in Simple and Compound Engines" described a test in which the load employed was a Thomson-Houston generator delivering current to a water rheostat by means of which the resistance was varied to suit the conditions of the test.

The only distinctly electrical paper read was one by Mr. Anthony Victorin on the "Performance of an Overhead Traveling Crane Operated by a Single Electric Motor," and described that in use at the Watervliet Arsenal, West Troy, N. Y.

Between the sessions the members of the Society were pleasantly entertained in various ways and visited many points of special interest in the city and vicinity.

OBITUARY.

GEORGE H. MEEKER.

GREAT surprise and deep regret were expressed in this city at the sudden news of the death in Chicago of Mr. George H. Meeker, Western manager for the New York Insulated Wire Company. He was only 28 years old, and had but lately gone to Chicago to promote the interests with which he had for some time been connected. During a recent visit to New York, he contracted a cold, which on his return West developed serious symptoms, and in spite of all efforts he succumbed to peritonitis on December 5. He leaves a wife, but no children.

Mr. Meeker was a young man of much promise, bright, energetic, faithful, enterprising. He enjoyed the full confidence of his employers, and in return devoted his time and abilities wholly to the care of their large Western trade. Mr. Meeker was also public spirited, taking a lively concern in the prosperity of the Chicago Electric Club, and in the success of the electrical part of the World's Fair.

WILSON G. HUNT.

THE death is announced of Mr. Wilson G. Hunt, a retired and wealthy merchant of this city, at the age of 78. He was an active man of affairs for many years, and lent Prof. Morse his aid in the early days of the telegraph. He was at the time of his death a director in the Western Union Telegraph Company, and had also served as a director in more than one submarine cable company.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

Advertising is both wealth and fame to the judicious and liberal advertiser.

THE STANDARD ELECTRIC TIME COMPANY.

THE Standard Electric Time Company have contracted with the Cheney Bros., of South Manchester, Conn., to put in one of their new striking electric tower clocks, and a system of forty-eight electric dials, including the railroad depot and town hall. This will give South Manchester a uniform system of time that will be greatly appreciated, as all the dials will be controlled from one master clock, and this being corrected daily from observatory time signals will give correct and uniform time throughout the town and the works of the company.

A contract has also been signed for a large time plant, including an electric tower clock in the School for Deaf and Dumb at Fulton, Mo. This is the third institution of this kind to adopt the Warner system of electric time within a few months. The De La Vergne Refrigerating Machine Co., of New York, are also to adopt the Warner system, which is to displace another electric system which has not given satisfaction.

The electric tower clock made by this company, although a comparatively new thing, has given such general satisfaction in the past two years that it must supersede the old wind-up clock where exact time is required. Being controlled by a fine master clock in the building, the extremes of temperature have little or no effect upon the service. This company have not been so busy for months, and they are fast gaining a wide reputation for their system of time.

THE "PERFECT" ARC CUT-OUT.

THE latest bidder for popular favor is the new arc cut-out which the E. G. Bernard Company of Troy, New York, are at present making special efforts to push. This apparatus, shown in the accompanying illustrations, is of very simple construction and positive in action. It is made with a weatherproof case and with metal or glass face as desired. As originally made it contained wooden insulation, but porcelain is now used exclusively. The make and break does not depend on the quick motion of the hand of the operator, but has a very ingenious and quick acting spring attachment. The wire holes are in porcelain and the binding posts are fitted with a very novel shell-like clamp attachment which, it is claimed, make it impossible for the wires to become loose. A number of the largest stations in the country are at present using this cut-out with excellent results. The E. S. Greeley & Co., of this city, are the New York agents for this device.

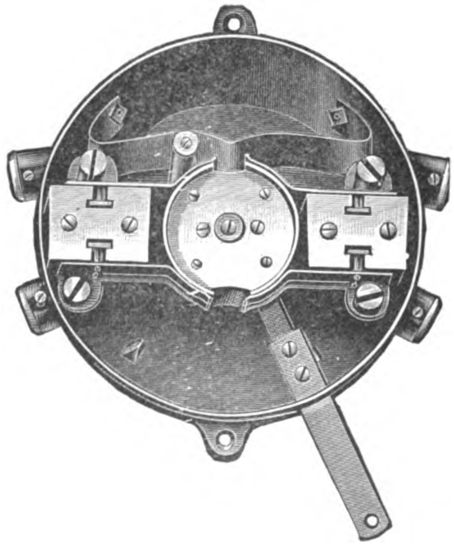

FIG. 1.—"PERFECT" ARC CUT-OUT.

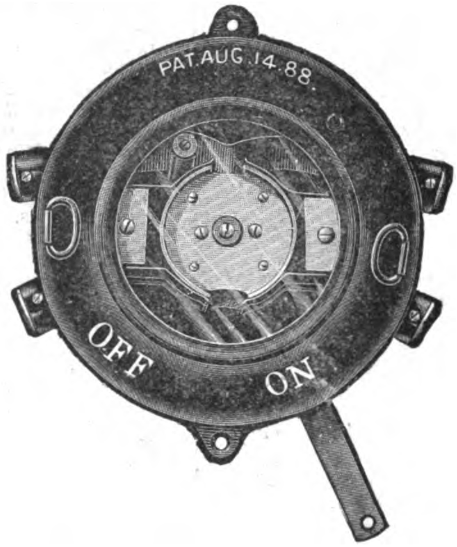

FIG. 2.—"PERFECT" ARC CUT-OUT.

ELECTRIC LIGHTING BIDS.

THE regular bids for electric lighting have been made in New York and Philadelphia, the rates in the latter case being a little lower than last year. There are no new bidders in New York, and prices for about 2,000 lights range from 40 up to 50 cents.

WESTERN NOTES.

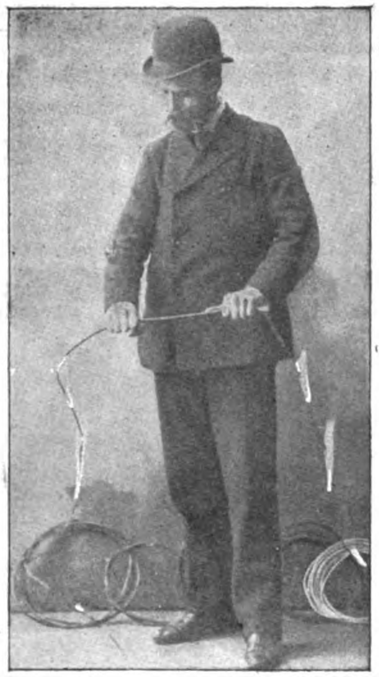
MR. C. M. GIDDINGS, president and general manager of the Sioux City Engine Works, Sioux City, Iowa, was among the World's Fair City visitors last week. Mr. Giddings reports having just completed the erection and starting up of one of their 24 x 48 Sioux City Corliss engines for the Burlington, Ia., Electric Light and Power Company. This is the smaller one of a pair originally designed for the station, the second of which will be a 500 h. p. compound condensing engine of same make. The engine is giving entire satisfaction. This company has also just secured a contract from the city of Hannibal, Mo., for a 22 x 48 Sioux City Corliss. The order was given to this company in the face of keen competition, after an inspection by the city council of the engines working at Dubuque, Ia. They have just ready for shipment to the Imperial Mill at Duluth, a 450 h. p. cross-compound Corliss. Business seems unusually good at this season of the year and prospects are excellent. They expect to enlarge their works very soon, the output of this year nearly doubling that of last.

MR. FRANK MCMASTER, traveling representative of George Cutter has returned from a Western trip during which he carried with him one of the new Cutter non-inductive volt meters and afforded the central station men convincing proof that the instrument is non-inductive and not subject to any temperature error. He reports that every one who saw it was greatly pleased with the way it worked. He also found business in all lines of specialties he carries very brisk and the outlook of a highly encouraging nature.

MR. HORACE A. CUSHING and Mr. Samuel F. B. Morse have been appointed general Western agents for Day's Kerite wire and cables, under the firm name of Cushing & Morse to succeed F. W. Cushing, who has resigned. Mr. F. W. Cushing goes to Europe on private business. Mr. Morse is a grandson of Prof. S. F. B. Morse, inventor of the telegraph.

MR. H. R. KINSELBACH, formerly of the Short Electric Company and late with the Electrical Construction Department of the World's Fair, has accepted a position as assistant superintendent with the Siemens and Halske Electric Company.

AN EXTRAORDINARY PERFORMANCE WITH "SALAMANDER" WIRE.



A MONTH or two ago some very interesting tests were made of a new insulated wire at the Edison station in this city before a body of experts and electrical insurance inspectors. This wire, known as the "Salamander," the invention of Mr. C. T. Snedekor, and manufactured by Washburn & Moen, was put through a series of tests with other wires, and remained practically intact, even when the others had gone up in smoke, and actually while the copper that it covered was melted out. During October, Mr. Snedekor made a similar exhibit at the Cleveland Street Railway Convention; and on November 1, in Boston, before a gathering of electrical men, he gave the startling performance illustrated in our cut. Taking a number of pieces of various insulated wires and joining them together, he had a current of 150 amperes passed through the circuit. As will be seen, the current destroyed the pieces shown bursting into flames, but the section of "Salamander" which Mr. Snedekor held in his hand, as shown, remained in a cool condition, so that in spite of the risk he would have run with ordinary wire, he was the calmest and least concerned member of the party.

It might be said that this remarkable exhibition was a mere tour de force, but it has now been made too often to be mere legerdemain; and it is understood that the manufacturers have subjected the wire for their own satisfaction to ordeals even more crucial as to its fireproof and waterproof qualities alike. The wire is not a low priced one, but the demand for it has already assumed very large proportions, and the facilities for production have been increased. Should the "Salamander" prove equal to the test of age, which there is little reason to doubt, it will be one of the most valuable additions of late years to the list of high class insulated wires.

McINTOSH, SEYMOUR & COMPANY.

MESSRS. McINTOSH, SEYMOUR & COMPANY, of Auburn, N. Y., still continue to run 23 hours a day, as they have done for the last four years, and have orders on hand for a good many engines, of which the principal ones are as follows:

One 1,200 h. p. double tandem compound condensing railway engine for the Syracuse Electric Light & Power Company, Syracuse, N. Y., with ball and socket self-oiling pillow block bearings and auxiliary shafts carrying the eccentrics and governor. This engine will have a wheel 7 feet face to carry two belts, and a shaft 16 inches in diameter. It will weigh 125 tons. One 600 h. p. four cylinder vertical triple expansion engine, for the Elmira Illuminating Company, Elmira, N. Y., fitted with double valves to each cylinder, one for the exhaust and compression, and the other for the admission and cut-off. Two 350 h. p. tandem compound condensing railway engines are also being made for the same company at Elmira.

One 600 h. p. double tandem compound, Hoboken Electric Light Company, Hoboken, N. J.; one 500 h. p. double tandem compound, Pennsylvania Railroad, Jersey City; two 500 h. p. standard, self-contained compound condensing, Citizens' General Electric Company, Louisville, Ky.; one 500 h. p. standard self-contained compound condensing, East River Electric Light Company, New York City; one 500 h. p. standard self-contained compound condensing, Edison Illuminating Company, New York City. The two last mentioned are the largest and heaviest self-contained compound engines made in the country. They weigh 40 tons each. The shafts are 11 inches in diameter; two 400 h. p. standard compound, Halifax Illuminating & Motor Company, Halifax, N. S.; one 350 h. p. standard self-contained compound, Consolidated Electric Light & Power Company, Dover, N. H.; one 250 h. p. standard compound, Baltimore Traction Company, Baltimore, M. D.; two 250 h. p. standard compound, City of Durban, South Africa; three 150 h. p. standard compound, Union Electricitats-Gesellschaft, Berlin, Germany; one 75 h. p. standard compound engine for Adolph Sutro, San Francisco, Cal.; one 200 h. p. single cylinder, Woburn Electric Light Company, Woburn, Mass.; one 200 h. p. single cylinder, Washington, D. C.; one 125 h. p. single cylinder, Cooperstown Electric Company, Cooperstown, N. Y.; one 150 h. p. single cylinder, Sing Sing, N. Y.; one 100 h. p. single cylinder, Lexington, Mass.; one 75 h. p. direct coupled single cylinder, North Chicago Street Railway Company, Chicago, Ill.; three 55 h. p. single cylinder, East River Gas Company, New York City, and other small engines.

They are also making a 1,200 h. p. engine for the World's Fair, to be direct belted, and one direct coupled 300 h. p. railroad engine, and one 300 h. p. direct coupled alternating outfit.

ELECTRIC FIXTURES OF THE NEW JERSEY LAMP AND BRONZE WORKS.

AN extensive gas and electric fixture department has been established by the above works at New Brunswick, N. J., under Mr. G. Wilfred Pearce, superintendent, the special department being in charge of Mr. Ralph W. Booth as general manager. This branch promises to become very important in the immediate future, and is already doing admirable work with excellent results. The factory is a fine four-story brick building, employing ordinarily from 150 to 200 hands, and the number runs much higher in the season.

The Works have a most complete line of fixtures, and keep a corps of experienced and skilful designers at work on new ideas all the time. The management is fully aware of the higher artistic taste now shown by the public in these matters, and is in closest sympathy with every demand for beauty of form and exquisite finish.

A special catalogue of electrical fixtures has just been issued by the works, and gives a good idea of their productions, being handsomely illustrated and tastefully printed. We reproduce herewith two or three of the designs intended for use as standards for newel posts, etc., and to carry either the common incandescent lamp or that which is now made up as a wax taper. These are but examples of a great variety, and we would recommend our readers to see the fixtures for themselves or to write for a copy of the beautiful catalogue. An industry thus aiming to put artistic products within everybody's reach at moderate prices is worthy of hearty support.

ELECTRIC FIXTURES OF THE NEW JERSEY LAMP AND BRONZE WORKS.

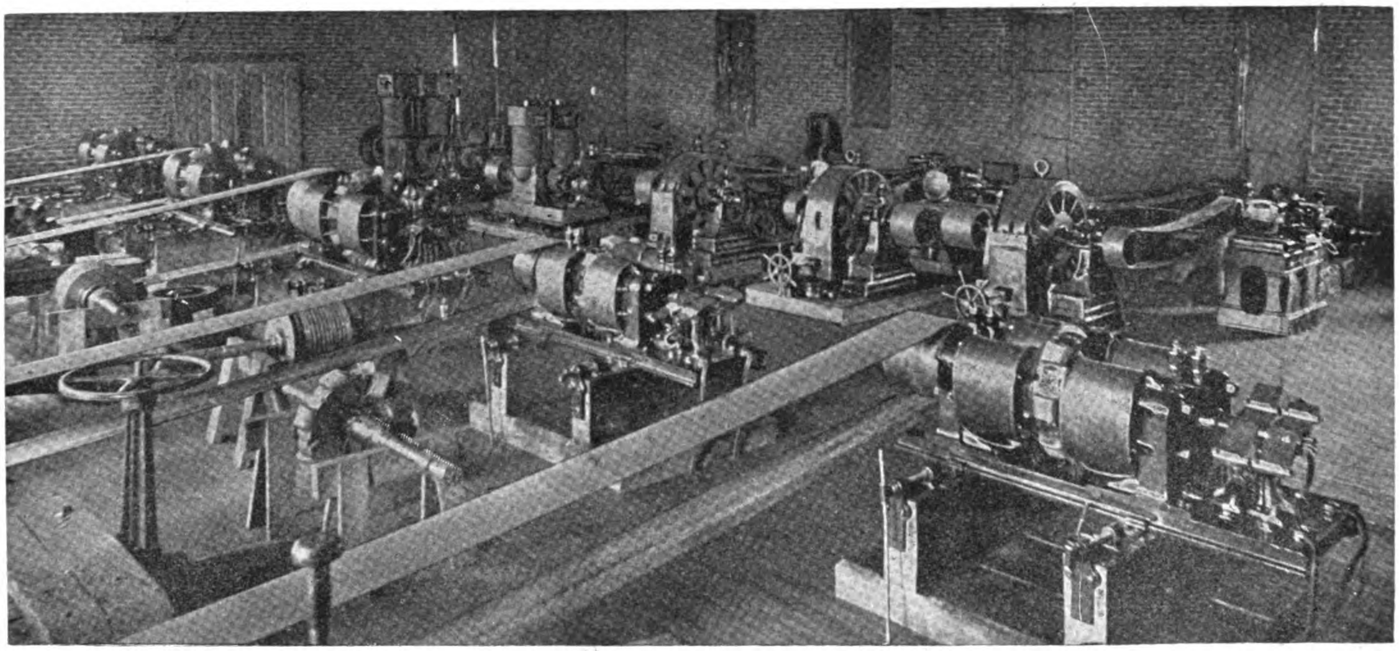
PELTON WATER WHEELS AT ROARING FORK, COLORADO.

One of the first attempts to operate the machinery of mills and mines by electric transmission on a large scale was that made by the Roaring Fork Electric Light and Power Company, at Aspen, Colorado, a part of whose plant is shown in the accompanying illustration.

The power station is located near the mining town of Aspen, in the heart of the Rocky Mountain range—a place of some 7,000 inhabitants—having an elevation of nearly 8,000 feet. Water is brought to the station in a single line of pipe consisting of 500 feet of 16 inch, and 3,500 feet of 14 inch—which discharges into a receiver from which short connections are made to the wheels. The power plant consists of eight 24 inch Pelton wheels which run 1,000 revolutions under a head of 820 feet, with a maximum capacity of 175 h. p. each, aggregating some 1,400 h. p.

Each wheel runs a separate generator, and connection is made by belt direct without intermediate gearing, the power developed being made to conform to the requirements by the use of reducing tips so that only as much water is applied to the wheels as is necessary to run the generators at proper speed.

The wheels weigh but 90 lbs. each and therefore show a capacity of nearly 2 h. p. for every pound of material and including accessories to make the plant complete, such as shafting, boxes, pulleys, gates, nozzles, etc., the proportion would be 4½ lbs. to every h. p. developed. Excellent regulation is afforded by the Doolittle automatic governor which controls the speed of the wheels perfectly under wide variations of load and what are regarded as very exacting conditions generally.



Electric Transmission Plant for All Services, Aspen, Colorado.

The light plant consists of three Brush 60-light arc dynamos, two Brush 450-light incandescent dynamos, of three Westinghouse alternating current machines of 750 lights each. The entire town of Aspen is lighted from this station as well as many mills, mines and sampling works in the vicinity.

The power plant consists of one 80 k. w. and one 40 k. w. Edison power generator. The power thus generated is used for operating mills, hoists, pumps, tramways, etc., as well as various other mining operations within a radius of three to four miles from the generating station.

This station has been in continuous operation for three years with practically no expense in the way of repairs nor interruption of any moment to the service, notwithstanding the severity of the weather encountered in such an altitude during a part of the year.

THE CONCORD LAND AND WATER-POWER COMPANY.

For some time the Concord Land and Water-Power Company have held the valuable property at Sewall's Falls, N. H., with the intention of utilizing the power for electrical transmission. A dam 500 feet long, of the very best possible construction, designed by Messrs. H. F. Mills, C. E., Lawrence, Mass., and E. F. Smith, C. E., Reading, Pa., assisted also by J. R. Freeman, C. E., 31 Milk street, Boston, is now being constructed there by Wm. H. Ward, contractor. It is about half done and is rapidly approaching completion. When completed it will give 5,000 h. p.

The Company have, at present, contracts for a very large amount of electrical work and a power house 150 feet x 40 feet will be constructed. The water wheels are to be furnished by the Rodney-Hunt Machine Company, of Orange, Mass.

The Company have secured the contract for lighting Concord for a term of ten years, and are temporarily doing the work by a steam plant arranged for the purpose. The other contracts consist of a large amount of motor service, including the new works of the Page Belting Company, and a portion of their old works, which will require eight motors, and a large amount of work upon the granite quarries, and in the granite sheds for polishing, cutting, etc. This is in addition to many motors in the city of Concord for manufacturing and other purposes.

A large amount of commercial lighting, both arc and incandescent, has been contracted for, and the company will start with a business which, they consider, will assure their financial success.

THE USE OF 500-VOLT MOTORS.

Mr. G. M. Angier, the general agent of the Mather Electric Company, writes us as follows:

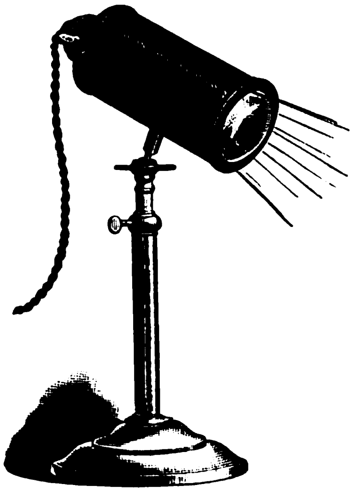
"We note with interest the editorial which appeared in your issue of last week regarding 500-volt motors. We find that the demand for motors wound for that voltage is rapidly increasing, and central station manufacturers and others are gradually adopting 500-volts as a standard potential for motor circuits. Up to within two years ago nine-tenths of the motors built by us were wound for 210 or 220 volts. To-day the case is reversed. Nearly all our motors are wound for 500 volts.

"Customers find the distribution of current can be accomplished more economically than with the lower voltages. The motor runs better and at a more constant speed. Carbon brushes may be used to better advantage; thus greatly reducing the wear of the commutator.

"Factories located in the vicinity of water powers are gradually adopting electricity for power purposes. Of course its advantages are many. Shafting, belting, etc., are entirely done away with. The different departments can be operated entirely independently of each other. With the lower voltages it was almost impossible to carry current any distance, and factories located within a mile or two of a splendid water power were obliged to use steam. With a voltage of 500 the question is easily solved and can be economically accomplished. Many central stations are installing and operating independent motor circuits, and in the majority of such cases they have adopted a potential of 500 volts.

"The great trouble with many of the 500-volt motors that were first placed on the market was the question of insulation. This, however, has been entirely overcome, and to-day the 500-volt motor certainly has many advantages over those wound for 210 or 220 volts."

THE DELAVAN LARYNGOSCOPIC ELECTRIC LIGHT CONDENSER FOR PHYSICIANS.



Delavan Laryngoscope.

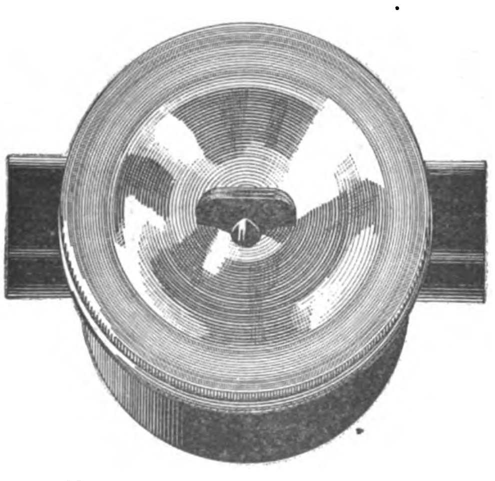
THE proceedings of the American Electro-Therapeutical Association prove abundantly that the leading members of the medical profession have at last recognized the great value of electricity, both as a remedial agent, and as a practical means of performing many of the minor surgical operations which were formerly done with the knife and the cautery iron. In order to keep step with the ever increasing demands of the profession, the supply trade have had to turn more particular attention to this branch of the business, and among others, the Edison Manufacturing Company are now turning out many novelties which will prove of interest to the profession.

They have recently perfected an optical condenser devised by them for Dr. Delavan, of this city, for use with the street current, which throws a perfectly clear beam from the head mirror, doing away with the shadow which is invariably thrown from the incandescent lamp, as ordinarily used.

The accompanying engraving will give a general idea of the outfit. The condenser is attached with a ball and socket to an adjustable standard, enabling the physician to use it at any height or angle required. It can be seen in operation at the offices of the company, No. 110 East Twenty-third street, New York City.

A NEW "E. E. & S." SNAP SWITCH.

THE accompanying illustration shows an incandescent snap switch neatly encased in an iron receptacle, made by the Electric Engineering and Supply Company, of Syracuse, N. Y. It is especially designed for the conduit system of wiring, and the receptacle will admit a 5 and 10 ampere switch, either single or double pole. They are made in a variety of styles and can be located almost anywhere on the line, and have openings to accommodate any sized tube, single or duplex. The receptacle can be inserted into the walls when the building is in course of erection, and the switch put in and connection made at any time thereafter to suit the convenience of the builder. The covers are concave, forming a deep recess, by means of which the key or thumb piece is set into the receptacle and does not protrude from the wall. This cover is easily removed by detaching the key and then a slight turn in either direction will lay the switch open for inspection or making connection. A highly polished ring encircles the opening of the box, and protects the decoration or frescoing from soiled hands when the cover is removed for repair. The receptacle is furnished with E. E. & S. switches especially constructed for the purpose. The cover can be furnished to match any other hardware.

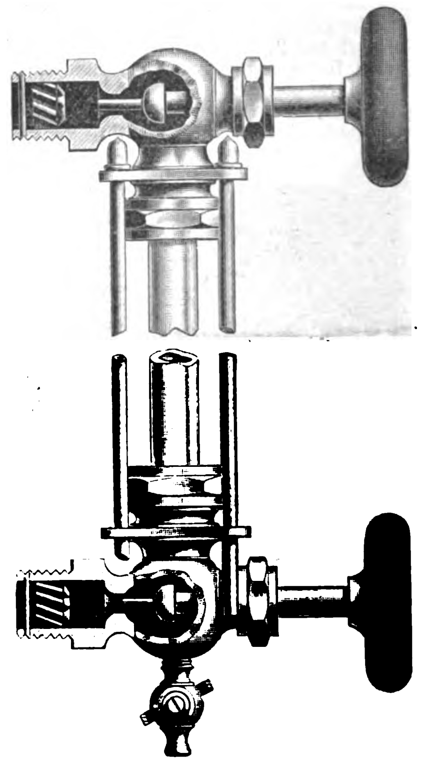


NEW "E. E. & S." SNAP SWITCH.

The same idea is applied to ceiling cut-outs, and a receptacle a little differently constructed is equipped with the E. E. & S. rosette, especially made for this design. Here a convex cover is used provided at the centre with a hard rubber insulating bushing through which the cord passes. A number of the large buildings recently erected in New York are fitted up with these devices.

THE ASHLEY AUTOMATIC WATER GAUGE.

THE accompanying illustration represents a sectional view of a new automatic water gauge manufactured by the Ashley Engineering Company, of Hawthorne, N. J., whose New York office is at 186 Liberty street. A particular point of interest is noticed in the pipe leading to the glass gauge, which has a round plug or valve, having on its outer radius spiral wings or flanges; while the glass remains unbroken the water continues balanced on the water line by the steam in the upper part of the gauge; upon breaking the glass, however, the rush of steam and water to the atmosphere carries the sliding valve to the seat, as shown in the illustration. By adjusting the pin at the end of the outer valve so that the steam gets a vent through the valve seat, and alternately opening and closing the outer valve, the steam rapidly revolves the inner or rotating valve and, as it comes to its seat, it regrinds the valve seat each time the process is repeated, and at the same time cleans the valve chamber from all deposit or sediment.



ASHLEY AUTOMATIC WATER GAUGE.

It is claimed that with these gauges in use there is absolutely no danger of being scalded as is the case in breakage. Should the glass be broken during the night, as is often the case, the steam and water are instantly shut off. The device will undoubtedly prove of value to engineers of central and power stations.

QUICK WORK BY THE DIRECT CABLE COMPANY.

THE United Press, having occasion on the forenoon of Dec. 8, to send to the Central News, London, an inquiry relating to some ordinary business matter, filed a dispatch at the office of the Direct Cable Company in this city, and in exactly ten and one-half minutes afterward a reply was laid on the desk of General Manager Phillips. Quicker work than this has, of course, often been done not only by the Direct Company, but by the other cable companies as well, but the foregoing record has seldom been equalled except when extraordinary effort to do so has been made. This was in the regular, humdrum course of business.

THE
Electrical Engineer.

VOL. XIV. DECEMBER 21, 1892. No. 242.

ON THE DISSIPATION OF THE ELECTRICAL ENERGY OF THE HERTZ RESONATOR.

BY

Nikola Tesla

ANYONE who, like myself, has had the pleasure of witnessing the beautiful demonstrations with vibrating diaphragms which Prof. Bjerknes, exhibited in person at the Paris Exposition in 1889, must have admired his ability and painstaking care to such a degree, as to have an almost implicit faith in the correctness of observations made by him. His experiments "On the Dissipation of the Electrical Energy of the Hertz Resonator," which are described in the issue of Dec. 14, of THE ELECTRICAL ENGINEER, are prepared in the same ingenious and skillful manner, and the conclusions drawn from them are all the more interesting as they agree with the theories put forth by the most advanced thinkers. There can not be the slighest doubt as to the truth of these conclusions, yet the statements which follow may serve to explain in part the results arrived at in a different manner; and with this object in view I venture to call attention to a condition with which, in investigations such as those of Prof. Bjerknes, the experimenter is confronted.

The apparatus, oscillator and resonator, being immersed in air, or other discontinuous medium, there occurs—as I have pointed out in the description of my recent experiments before the English and French scientific societies—dissipation of energy by what I think might be appropriately called *electric sound waves* or *sound-waves of electrified air*. In Prof. Bjerknes's experiments principally this dissipation in the resonator need be considered, though the sound-waves—if this term be permitted—which emanate from the surfaces at the oscillator may considerably affect the observations made at some distance from the latter. Owing to this dissipation the period of vibration of an air-condenser can not be accurately determined, and I have already drawn attention to this important fact.

These waves are propagated at right angles from the charged surfaces when their charges are alternated, and dissipation occurs, even if the surfaces are covered with thick and excellent insulation. Assuming that the "charge" imparted to a molecule or atom either by direct contact or inductively is proportionate to the electric density of the surface, the dissipation should be proportionate to the square of the density and to the number of waves per second. The above assumption, it should be stated, does not agree with some observations from which it appears that an atom can not take but a certain maximum charge; hence, the charge imparted may be practically independent of the density of the surface, but this is immaterial for the present consideration. This and other points will be decided when accurate quantitative determinations, which are as yet wanting, shall be made. At present it appears certain from experiments with high-frequency currents, that this dissipation of energy from a wire, for instance, is not very far from being proportionate to the frequency of the alternations, and increases very rapidly when the diameter of the wire is made exceedingly small. On the latter point the recently published results of Prof. Ayrton and H. Kilgour on "The Thermal Emissivity of Thin Wires in Air" throw a curious light. Exceedingly thin wires are capable of dissipating a comparatively very great amount of energy by the agitation of the surrounding air, when they are connected to a source of rapidly alternating potential. So in the experiment cited, a thin hot wire is found to be capable of emitting an extraordinarily great amount of heat, especially at elevated temperatures. In the case of a hot wire it must of course be assumed that the increased emissivity is due to the more rapid convection and not, to any appreciable degree, to an increased radiation. Were the latter demonstrated, it would show that a wire, made hot by the application of heat in ordinary ways, behaves in some respects like one, the charge of which is rapidly alternated, the dissipation of energy per unit of surface kept at a certain temperature depending on the curvature of the surface. I do not recall any record of experiments intended to demonstrate this, yet this effect, though probably very small, should certainly be looked for.

A number of observations showing the peculiarity of very thin wires were made in the course of my experiments. I noted, for instance, that in the well-known Crookes instrument the mica vanes are repelled with comparatively greater force when the incandescent platinum wire is exceedingly thin. This observation enabled me to produce the spin of such vanes mounted in a vacuum tube when the latter was placed in an alternating electrostatic field. This however does not prove anything in regard to radiation, as in a highly exhausted vessel the phenomena are principally due to molecular bombardment or convection.

When I first undertook to produce the incandescence of a wire enclosed in a bulb, by connecting it to only *one* of the terminals of a high tension transformer, I could not succeed for a long time. On one occasion I had mounted in a bulb a thin platinum wire, but my apparatus was not adequate to produce the incandescence. I made other bulbs, reducing the length of the wire to a small fraction; still I did not succeed. It then occurred to me that it would be desirable to have the surface of the wire as large as possible, yet the bulk small, and I provided a bulb with an exceedingly thin wire of a bulk about equal to that of the short but much thicker wire. On turning the current on the bulb the wire was instantly fused. A series of subsequent experiments showed, that when the diameter of the wire was exceedingly small, considerably more energy would be dissipated per unit surface at all degrees of exhaustion than was to be expected, even on the assumption that the energy given off was in proportion to the square of the electric density. There is likewise evidence which, though not possessing the certainty of an accurate quantitative determination, is nevertheless reliable because it is the result of a great many observations, namely, that with the increase of the density the dissipation is more rapid for thin than for thick wires.

The effects noted in exhausted vessels with high-frequency currents are merely diminished in degree when the air is at ordinary pressure, but heating and dissipation occurs, as I have demonstrated, under the ordinary atmospheric conditions. Two very thin wires attached to the terminals of a high-frequency coil are capable of giving off an appreciable amount of energy. When the density is very great, the temperature of the wires may be perceptibly raised, and in such case probably the greater portion of the energy which is dissipated *owing to the presence of a discontinuous medium* is transformed into heat at the surface or in close proximity to the wires. Such heating could not occur in a medium possessing either of the two qualities, namely, perfect incompressibility or perfect elasticity. In fluid insulators, such as oils, though they are far from being perfectly incompressible or elastic to electric displacement, the heating is much smaller because of the continuity of the fluid.

When the electric density of the wire surfaces is small, there is no appreciable local heating, nevertheless energy is dissipated in air by waves, which differ from ordinary sound-waves only because the air is electrified. These waves are especially conspicuous when the discharges of a powerful battery are directed through a short and thick metal bar, the number of discharges per second being very small. The experimenter may feel the impact of the air at distances of six feet or more from the bar, especially if he takes the precaution to sprinkle the face or hands with ether. These waves cannot be entirely stopped by the interposition of an insulated metal plate.

Most of the striking phenomena of mechanical displacement, sound, heat and light which have been observed, imply the presence of a medium of a gaseous structure, that is, one consisting of independent carriers capable of free motion.

When a glass plate is placed near a condenser the charge of which is alternated, the plate emits a sound. This sound is due to the rythmical impact of the air against the plate. I have also found that the ringing of a condenser, first noted by Sir William Thomson, is due to the presence of the air between or near the charged surfaces.

When a disruptive discharge coil is immersed in oil contained in a tank, it is observed that the surface of the oil is agitated. This may be thought to be due to the displacements produced in the oil by the changing stresses, but such is not the case. It is the air above the oil which is agitated and causes the motion of the latter; the oil itself would remain at rest. The displacements produced in it by changing electrostatic stresses are insignificant; to such stresses it may be said to be compressible to but a very small degree. The action of the air is shown in a curious manner for if a pointed metal bar is taken in the hand and held with the point close to the oil, a hole two inches deep is formed in the oil by the molecules of the air, which are violently projected from the point.

The preceding statements may have a general bearing upon investigations in which currents of high frequency and potential are made use of, but they also have a more direct bearing upon the experiments of Prof. Bjerknes which are here considered, namely, the "skin effect," is increased by the action of the air. Imagine a wire immersed in a medium, the conductivity of which would be some function of the frequency and potential difference but such, that the conductivity increases when either or both of these elements are increased. In such a medium, the higher the frequency and potential difference, the greater will be the current which will find its way through the surrounding medium, and the smaller the part which will pass through the central portion of the wire. In the case of a wire immersed in air and traversed by a high-frequency current, the facility with which the energy is dissipated may be considered as the equivalent of the conductivity; and the analogy would be quite complete, were it not that besides the air another medium is present, the total dissipation being merely modified by the presence of the air to an extent as yet not ascertained. Nevertheless, I have sufficient evidence to draw the conclusion, that the results obtained by Prof. Bjerknes are affected by the presence of air in the following manner: 1. The dissipation of energy is more rapid when the resonator is immersed in air than it would be in a practically continuous medium, for instance, oil. 2. The dissipation owing to the presence of air renders the difference between magnetic and non-magnetic metals more striking. The first conclusion follows directly from the preceding remarks; the second follows from the two facts that the resonator receives always the same amount of energy, independent of the nature of the metal, and that the magnetism of the metal increases the impedance of the circuit. A resonator of magnetic metal behaves virtually as though its circuit were longer. There is a greater potential difference set up per unit of length, although this may not show itself in the deflection of the electrometer owing to the lateral dissipation. The effect of the increased impedance is strikingly illustrated in the two experiments of Prof. Bjerknes when copper is deposited upon an iron wire, and next iron upon a copper wire. Considerable thickness of copper deposit was required in the former experiment, but very little thickness of iron in the latter, as should be expected.

Taking the above views, I believe, that in the experiments of Prof. Bjerknes which lead him to undoubtedly correct conclusions, the air is a factor fully as important, if not more so, than the resistance of the metals.

STATISTICS OF ELECTRICAL MANUFACTURE IN GERMANY.

THE following statistics with regard to the value of electrical goods manufactured in Germany, and relating to the years 1890 and 1891, were recently given by the *Elektrotechnische Zeitschrift* on the authority of Herr Fr. Vogel. Telegraphic apparatus to the value of $280,000 was made; telephones, over $400,000; railway signalling apparatus, nearly $400,000; total, with electric bells, etc., about $2,000,000. During 1890–1891: 3,500 continuous current dynamos, alternators and transformers were built each year to the value of $1,600,000. In 1886 a large German firm built 350 machines, having a total output of 2,500,000 watts. Last year the same firm turned out 760 machines, the total output of which was 10,000,000 watts, the average size of machine being, therefore, about 9½ h. p. and 17½ h. p. respectively. Accumulators are being manufactured and sold in Germany to the amount of $1,120,000 per annum. About 17,000 arc lamps are made every year, their value being about $500,000. The arc-light carbon product amounts to nearly $400,000 per annum, and the incandescent lamp product to $640,000. The value of the total annual electrical output of all sorts is placed at $6,600,000 or $6,700,000. The number of persons employed in electrical factories is about 15,000.

MAXIMUM SPEED ON ELECTRIC RAILWAYS.

IN a contribution to the *Elektrotechnische Zeitschrift*, Mr. J. Kraemer comments on the current statements regarding high speed on electric railways, and presents an array of formulas for calculating the effect of air pressure, dead weight and other factors on the maximum possible speed. He thinks that 500 kilometres per hour is the highest speed yet attained by experiments made on a laboratory scale; the dead weight of the cars, engine, trucks and the fuel used reduces this to about 150 kilometres. The limited rate of reciprocation of the steam engine part of the locomotive suggests larger driving wheels, but the size of these is limited by the radius of the curves. These factors, together with the allowances for air resistance, slipping on the rails and the average grades still further reduce this speed, so that electric railways must be able to alter the conditions materially in order to attain a speed of even 200 kilometres per hour, corresponding to about 125 miles per hour—quite a promising figure.

TABLES SHOWING PERMISSIBLE AMPERAGE AND DEPTH OF WINDING FOR COTTON COVERED WIRE.

BY

Walter S. Dix

On pages 818 and 819 of the fourth edition of Thompson's "Dynamo-Electric Machinery," is given an "Amperage Table," based upon current densities of 1,000 to 4,000 amperes per square inch of copper in conductors. As this basis is purely arbitrary and moreover does not, in most cases, agree with the best practice, the writer has calculated the accompanying tables, founded upon a more rational idea, viz., the rate of emissivity for a given rise of temperature.

For armatures, it is approximately correct to say that .9 of a watt per square inch will be dissipated for a rise in temperature of 35° C., that being the result of Esson's experiments (Thompson, page 429); while .4 of a watt per square inch is dissipated in stationary magnets for a rise of 35° C., both figures being borne out by experience as substantially correct.

Table I is calculated for an emissivity of .9 watt per square inch and for *double* cotton covered wire, which is almost always used in armatures. Table II is calculated for an emissivity of .4 watt, and for *single* cotton covered wire, as being most frequently employed for magnets,

TABLE II.

PERMISSIBLE AMPERAGE

AND

PERMISSIBLE DEPTH OF WINDING

FOR

MAGNETS WITH SINGLE COTTON COVERED WIRE.

TABLE I.

TABLE I.—PERMISSIBLE AMPERAGE AND PERMISSIBLE DEPTH OF WINDING FOR ARMATURES WITH DOUBLE COTTON COVERED WIRE.

TABLE III.—PERMISSIBLE AMPERAGE AND PERMISSIBLE DEPTH OF WINDING FOR MAGNETS WITH DOUBLE COTTON COVERED WIRE.

except where large sizes are used, in which case Table III will be consulted, that being calculated for *double* cotton covered wire, and including only the large sizes.

The American Electrical Works standard insulation has been allowed, viz., .007 inch on No. 0 to No. 11 B. & S.; .005 inch on No. 12 to No. 24; and .0045 inch on No. 25 to No. 31 single; twice these values for insulation of double covered wires. Fifteen per cent. is allowed for imbedding of the wires.

The standard of resistance employed is that recommended by the committee of the American Institute of Electrical Engineers, which is 9.612 ohms per mil-foot at 0°. The running temperature of tables is taken at 25° + 35° = 60° C. The column giving the depth for one layer is, of course, the diameter over insulation.

The formula used in calculating the tables is,

$$C = \sqrt{\frac{12 \times W}{\frac{\omega_{mf}}{M} \times T \times L}}$$

where $C =$ current.
$W =$ emissivity in watts per square inch.
$\omega_{mf} =$ ohms per mil-foot.
$M =$ circular mils.
$T =$ turns per linear inch.
$L =$ number of layers in depth.

If great precision is sought in using the tables, it will be necessary to correct the figures showing permissible amperes for curvature of winding, by multiplying them by the co-efficient $k = \sqrt{\frac{2\,\rho}{\rho + \rho'}}$, where ρ and ρ' are the radius of surface of winding and the radius of core, respectively.

For ratios of $\frac{\rho}{\rho'} =$ 1.5, 1.4, 1.3, 1.2, 1.1, 1.05,
$k =$ 1.095, 1.08, 1.06, 1.04 1.02, 1.01.

But it is well enough to neglect the error, as it is on the safe side.

In some cases, for example, where armatures or magnet coils are cased in and circulation is very poor, it may be desirable to use a lesser rate of emission. Thus for a rate per square inch of

	.2	.3	.5	.6	.7	.8	Watt.
Multiply column of amperes by	—	—	.744	.816	.882	.942	in Table I.

ON THE EXACT ADJUSTMENT OF STANDARDS OF RESISTANCE AND THE DETERMINATION OF TEMPERATURE COEFFICIENTS.—I.

BY

Elmer G Willyoung

As a student and as a practical man to whom the work came as a matter of routine and necessity the writer has made considerable of a study for the last few years of the various methods of exactly adjusting single standards of resistance and of determining the temperature coefficients of such standards and of alloys in general. All the various methods have had careful trial, including those well known as well as those unknown to the profession. The writer has gone to considerable trouble to ascertain the methods used in the leading foreign laboratories, both commercial and scientific, and has diligently searched the foreign periodicals for many years back in quest of information with the result of obtaining many interesting and valuable suggestions. In a paper read before the Franklin Institute[1] somewhat over a year ago the writer briefly referred to some of the best known methods, their advantages and disadvantages, and concluded by expressing his decided preference for the "Carey-Foster" method of making very exact measurements; a piece of apparatus was then exhibited as being highly suitable for this kind of work and some of its capabilities were referred to. Since that time the apparatus and method have been in continual daily use in commercial work and much additional knowledge has been gained; although some defects in the apparatus have manifested themselves, still our confidence in its convenience and accuracy have been strengthened. In the use of the apparatus we have, I think, at one time or another been obliged to note every weak point in its theory or construction and to provide such temporary means as might be obtainable for getting around difficulties as they arose. On a basis of the experience thus obtained I have recently designed and built an improved form of this apparatus which is in every way greatly superior to the apparatus I then showed and which I believe, from reports which I have received of the apparatus used at the leading laboratories of the world for this same purpose, is capable of giving closer comparisons and of being used to obtain the value of a single standard to a higher degree of accuracy than any other arrangement of apparatus yet known. At the time of the reading of the paper above referred to I expressed myself as believing the apparatus to be capable of giving results correct to certainly within $\frac{1}{100}$ per cent. With the improved apparatus which I shall describe, in the hands of a skillful observer, I consider it entirely possible to determine the value of one coil in terms of another to an accuracy of $\frac{1}{500}$ per cent., and even greater.

The theory of the Carey-Foster method may be found fairly well worked out in a number of works[2]; it is as follows: Let Fig. 1 represent, diagrammatically, the orthodox slide wire bridge in which X is the unknown resistance (nearly equal to the coil S) to be accurately measured in terms of S; R$_1$ and R$_2$ are resistances roughly equal to one another and to S. The balance reading will then fall near the centre of the bridge. The heavy copper end straps are of resistances which may be designated by r_1 and r_6, the resistance of the other connectors by r_2, r_3, r_4 and r_5, as shown.

When a balance is obtained we have

$$\frac{R_1 + r_2 + r_3}{R_2 + r_5 + r_6} = \frac{X + r_1 + x_1\,\rho}{S + r_6 + (L - x_1)\,\rho} \qquad (1)$$

x_1 being the reading,
L " " whole length of the bridge wire,
ρ " " resistance of a single division of the bridge wire.

Reversing the position of X and S and balancing again we have:

$$\frac{R_1 + r_2 + r_3}{R_2 + r_4 + r_5} = \frac{S + r_1 + x_2\,\rho}{X + r_6 + (L - x_2)\,\rho} \qquad (2)$$

From (1) we have

$$\frac{R_1 + r_2 + r_3}{R_1 + R_2 + r_2 + r_3 + r_4 + r_5} = \frac{X + r_1 + x_1\,\rho}{X + S + 2\,r_1 + L\,\rho} \qquad (3)$$

and from (2)

$$\frac{R_1 + r_2 + r_3}{R_1 + R_2 + r_2 + r_3 + r_4 + r_5} = \frac{S + r_1 + x_2\,\rho}{X + S + 2\,r_1 + L\,\rho} \qquad (4)$$

$$\therefore X + r_1 + x_1\,\rho = S + r_1 + x_2\,\rho \qquad (5)$$

and $S - X = \rho\,(x_1 - x_2)$; or $X = S - \rho\,(x_1 - x_2)$; (6)

so that the unknown, X, differs from the standard, S, by exactly the resistance of the bridge wire over which the slider moves in changing from one position of balance to the other when the coils X and S are interchanged. We also see that the expression is entirely independent of the length of the bridge wire and also of the connecting coppers provided only that these last be symmetrical. We may, therefore, measure as small differences as we please by merely making the resistance of our bridge wire small enough.

---

[1] "Resistance Standards; their manufacture and adjustment." *Journal Franklin Institute*, April, 1892, also THE ELECTRICAL ENGINEER.

[2] See "Elementary Practical Physics," by Stewart & Gee, Vol. II., pp. 158, etc.

The earlier apparatus referred to, and which has been used in the daily routine of Queen & Company's laboratory, is shown in diagram in Fig. 2. This was a piece of apparatus by which the coils x and s of Fig. 1, could be quickly and easily interchanged. The design was first suggested by Prof. H. S. Carhart of Michigan University, in 1887, and the first piece was made by the writer while in attendance at that institution; it is still there and still being used as the "old reliable" for this class of work.

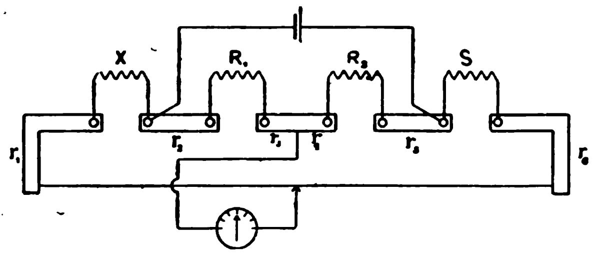

FIG 1.

Upon a suitable insulating base are mounted a number of copper straps and plates as shown; these are so arranged as to place four coils in exactly the same relation to one another as in Fig. 1, the lettering upon the two figures being the same. Coils x and s, have their terminals resting in mercury cups; the coils R_1 and R_2, being practically only extensions of the bridge arms, are simply fastened firmly into the binding posts. The galvanometer and battery circuits are as shown. In the centre of the apparatus are seen two groups of mercury cups, each group forming a square; these groups are connected together, as shown, by the heavy copper rods *c*. By now running around the circuit from the left, clock wise, it will be seen that the order is exactly the same as in Fig. 1. If now we alter the position of the heavy connecting rods *c*, to the position indicated by the dotted lines *d*, the coils x and s will be interchanged as will be readily obvious by again following around the circuit. In practice each pair of connectors is held in a little hard rubber platform so that but two movements are required to effect the change; being held loosely in the platform, they will adjust themselves to the surface of the bottom of the cup and thus make thoroughly good contacts.

Inspection will show that this apparatus is a perfectly symmetrical arrangement, and that, consequently, the connector resistances need not be considered; thus, with the commutator rods, as shown by the heavy lines and passing around the circuit from the bridge, clock wise, we have in circuit on the left, *g*, x and *h*, the other pieces being very obviously pairs; and on the right *f*, s and *e*. Turning the commutator through 90 degrees to the positions indicated by the dotted lines starting from the left, again we have *e*, s and *f*; and from the right *g*, x and *h*. Since $e = h$ and $f = g$ it is the same whether they are on one side or the other, and therefore only the resistances x and s have *really* been interchanged. To use this apparatus, it is only necessary to insert the two slotted terminal straps into one of the gaps of an ordinary slide wire bridge. In the work which we have been doing, we have been using a special form of slide bridge designed by the writer and having three wires, each a meter long, which can be thrown into multiple with one another if desired.

The first design, however, showed in practice a number of defects and sources of inconvenience. The first of these arises when we attempt to obtain the value of the resistances of the bridge wire per unit division. This, of course, might be obtained by connecting the ends of the wire directly to a "Wheatstone's bridge" arrangement and obtaining its resistance by ordinary methods. The resistance however, is necessarily very low as we shall see from the following considerations. Suppose we have a standard ohm and a resistance of platinoid nearly equal to the ohm, whose temperature coefficient we wish to determine exactly. We place the two coils in oil baths with both at, say, 15° C. and obtain a balance; we then carefully raise the temperature of the platinoid to, say, 30° C. and balance again. The difference in terms of resistance of the bridge wire will be the actual increase in resistance of the platinoid. The rise of resistance of platinoid per degree C. is about 0.00023; multiplying this by 15 we have 0.00345 ohm as about the actual increase of resistance due to the raising of the temperature from 15° to 30° C.

Let us suppose also that the value of the coefficient must be obtained to the fifth decimal place, or, in other words, that the resistance .00345 must be measured with a maximum error a trifle less than 0.00008 ohm. With the average slide wire bridge a skilled observer is able to set the slider, it may be assumed, successively, with a error of, say, not less than about $\frac{1}{10}$ mm. Consequently $\frac{1}{10}$ mm. of the wire must measure at least as low as 0.00008 ohm and hence the whole wire, 1,000 mms. long, will measure 10,000 times this, or $\frac{8}{10}$ ohm. To measure even as low a resistance as this even to $\frac{1}{25}$ per cent. is not at all an easy matter by ordinary methods. In practice the resistance of a meter wire should be as much less than the value given above as possible, as a greater length of wire would then be used when x and s were changed; non-uniformity would, consequently, become relatively less important, and errors of setting would bear a smaller ratio to the whole length used. It would also be much better, if possible, to measure the resistance of the bridge wire in terms of the resistance of the standard itself as we would thus eliminate any difference of adjustment between the single standard and any box which we might use for the purpose of measuring the resistance of the bridge wire by ordinary methods. We are, indeed, able to very accurately use this method and apparatus in measuring its own bridge wire. To do this we merely place a heavy short copper strap of negligible resistance in place of x and a resistance, Q, somewhat less than the resistance of the single wire, at the right, Fig. 1. Taking our two balances as before we have from (6)

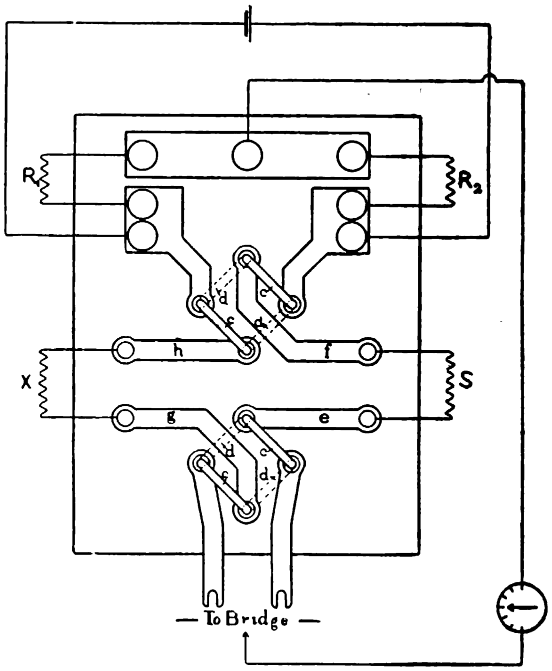

FIG 2.

$$Q - 0 = \rho(X_1 - X_2) \therefore \rho = \frac{Q}{X_1 - X_2} = \frac{Q}{\delta} \quad (8).$$

To find, now, the resistance of Q, place it in multiple with the standard, S, at the right, and again determine the difference, in this case S_2; we shall have

$$\frac{Q\ S}{Q + S} = \rho\ \delta_2 \qquad (9);$$

and, eliminating Q between (8) and (9) we have

$$\rho = S \times \frac{S_1 - S_2}{S_1\ S_2}.$$

Still a third way, which I have used a great deal, is to place a standard 1 and 10 ohm coil in multiple upon one side against a standard ohm coil on the other. In the early form which I have described it was very difficult to accomplish any of this placing in multiple as there was but one pair of mercury cups upon a side; consequently, we were obliged to make an accessory double pair of cups with connectors to hook into the regular standard cups; this introduced another mercury contact, in itself a bad thing, and also an additional copper resistance which disturbed the symmetry of the apparatus, and hence, the rigid accuracy of the preceding equations.

In the improved design of apparatus, shown in Fig. 3, provision has been made for the placing, if desired, of two coils upon each side, and this in a way which does not in the least disturb the original symmetry of the apparatus. In the diagrammatic sketch of this form, Fig. 4, there is shown a 10 and 1 ohm coil in multiple on one side against a 1 ohm on the other side; it will be observed, also, that the cups are so placed that the coils clear one another perfectly and have ample room about them for the necessary oil or water bath. The distance between these cups is $\frac{15}{16}$ inch, the usual distance between terminal coppers of the B. A. form of standards, which distance will, for the sake of uniformity, probably be retained by all instrument makers for a long time to come.

The resistance of the coils R_1 and R_2 disappears in the course of the measurement, as is seen from inspection of the equations (5) and (6). It is hence not necessary that the value of these resistances be known; all that is desired is that they should be approximately of the resistance of the coils under comparison, in order that the balance may fall near the centre of the wire and that their resistance should not change during the progress of the measurement. To insure this latter, it is sufficient to wind the two coils upon the same spool. In the Ann Arbor apparatus these two coils were simply enclosed in a plain, round wooden box. Later on it occurred to me, however, to place them upon a spool mounted upon a little stand having a pair of terminals upon each side fitting into the binding posts at T; the apparatus was thus compacted and made better appearing, and the coils could be more readily removed and others substituted in case standards of a greater or less value were to be compared. In this last design the spool itself is so made as to be removable from the platform instead of the whole platform having to be taken off. The terminals of the platform end in little copper binding posts, T, which receive terminal rods coming from the coils themselves; these coils are wound upon a spool enclosed in a small cylindrical brass case, S, mounted upon a rubber sub-base, P. Each case has engraved upon its top the values of the enclosed resistances as, $\frac{\text{“ 2 ”}}{\text{1 ohms}}$, $\frac{\text{“ 2 ’}}{\text{10 ohms}}$, etc.; if we desire to adjust 10-ohm standards instead of 1-ohm standards we merely unscrew the little milled head screws at the side of T, lift off the spool and replace it by another one, S, of suitable value.

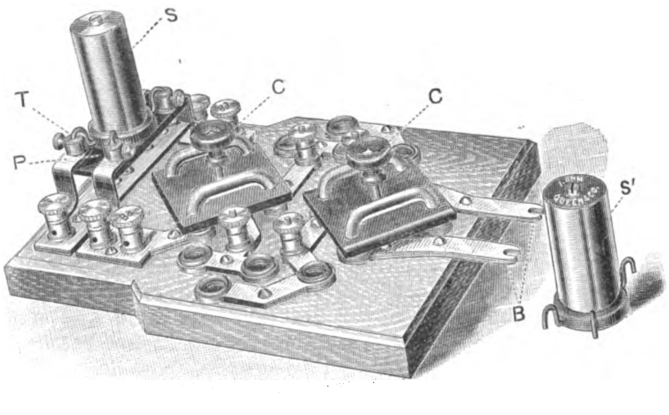

FIG. 3.—APPARATUS FOR COMPARING RESISTANCE STANDARDS.

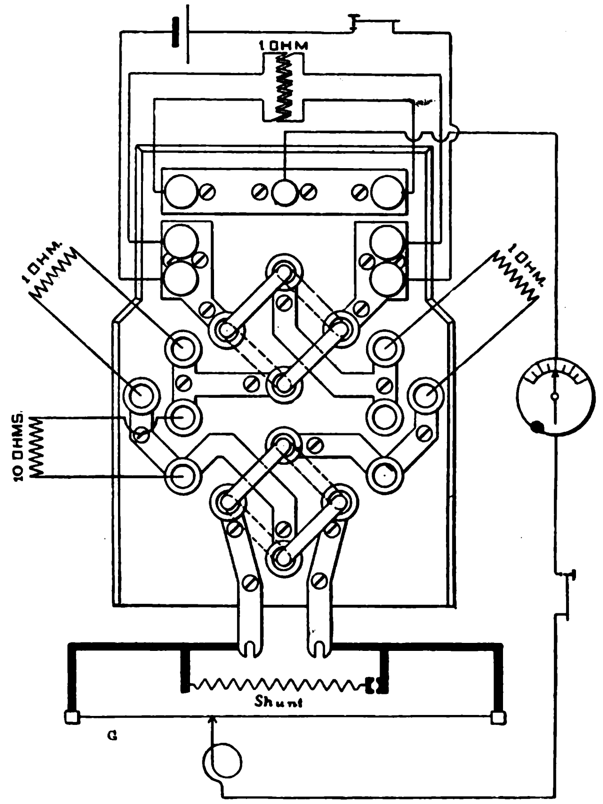

FIG. 4.

Obviously, any form of slide wire bridge may be used with this device. The best results will, however, be obtained by using a form of bridge specially adapted to the peculiar conditions met with. Several things are essential in a wire for use in applying this method. First, the divisions of the scale must be numerous and they must be accurate, since the actual *length* of wire moved over represents the difference in resistance between the two standards; second, the resistance of the wire must be *low*, so that as great a length as possible may be moved over in going from one balance to another; in this way any error of setting becomes, relatively, as small as possible, and errors of graduation are similarly affected; third, thermal currents must be reduced to the smallest minimum in order not to mask the exceedingly small E. M. F.'s representative of the small differences of resistance which we are measuring; fourth, it must be so constructed as to not easily get out of adjustment, and, lastly, it should be convenient to use. This last specification is, of course, a *general* one to be applied to *all* bridge wires.

AN ELECTRICAL ENTERTAINMENT.

AT a recent entertainment for the benefit of the Free Library of Rutland, Vt., Mr. M. J. Francisco devised some novel and very pleasing electrical effects. He showed how electricity could be applied to house-keeping in many ways with a great saving of labor.

THE ROPE DRIVEN ELECTRIC PLANT OF THE RACQUET CLUB, NEW YORK CITY.

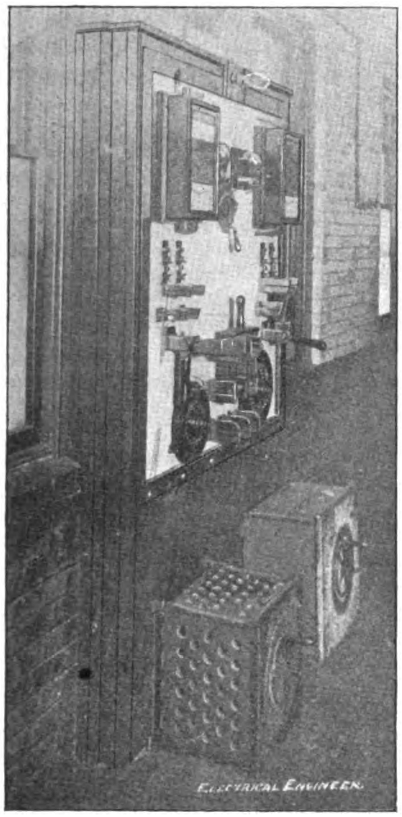

Fig. 3.—Switch Board Racquet Club.

The electric plant of the Racquet and Tennis Club, New York, demonstrates that the day of the so-called "system," at least for isolated plants, is past. Among the various kinds of electrical apparatus used in this plant, there are no two kinds made by any one manufacturing company. The apparatus best suited specially for the conditions was selected, regardless of system or manufacturing company, and the result is a combination of apparatus superior in average of excellence to that manufactured by any one of the manufacturing electric companies.

Here we find Ideal engines, a novel and ingenious endless rope driving gear, especially designed for this plant, Eickemeyer dynamos, Carpenter field rheostats, Weston voltmeters, Edison ampere meters and Ajax switches, an aggregation of superior apparatus, not half of which has ever been placed in combination before.

The problem presented by this case was an unusually difficult one, as the space was extremely limited and the avoidance of all noise and vibration was of the utmost importance. On account of the space at disposal and the noise, belts were out of the question. The space available was a long narrow strip 9 feet by 38 feet, shown in Figs. 1 and 2; and the two engines, two dynamos, the pumps, the heater and the switchboard had to be placed therein, the capacity of the plant being 1,000 16 c. p. lamps. The dynamos and engines could not be directly coupled on account of the narrowness of the space. The contractors were given full scope to secure the result, and devised a novel and ingenious modification of the single endless rope drive to meet the emergencies of the case, with the result that the plant is surprisingly noiseless and free from all vibration. The main peculiarity of this rope drive is that the tension pulley is fixed, and the slack of the rope is taken up by sliding the dynamo back as in ordinary belt practice.

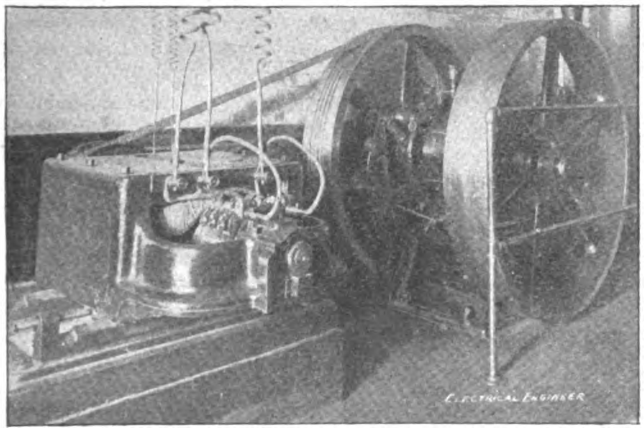

Fig. 1.—Rope Driven Dynamo Plant, Racquet Club, New York.

The limitation of space made the usual field rheostats prohibitory, and the Carpenter enamel rheostat was installed for this purpose for the first time, with very satisfactory results. The comparative spaces occupied by the rheostat of the ordinary type and the enamel rheostat is well shown in Fig. 3.

Prof. Francis B. Crocker, who acted as consulting engineer for this plant, deserves the thanks of the electrical profession for being the first consulting electrical engineer to recognize in a practical manner that, in electrical engineering even more than in other engineering practice, the best results should be obtained by utilizing the apparatus and methods representing the most recent improvements in the art and having the plant installed by engineers such as H. Ward Leonard & Company, the contractors for this,—free and able to take advantage of the best practice of to-day, and even to improve upon such practice should opportunity offer.

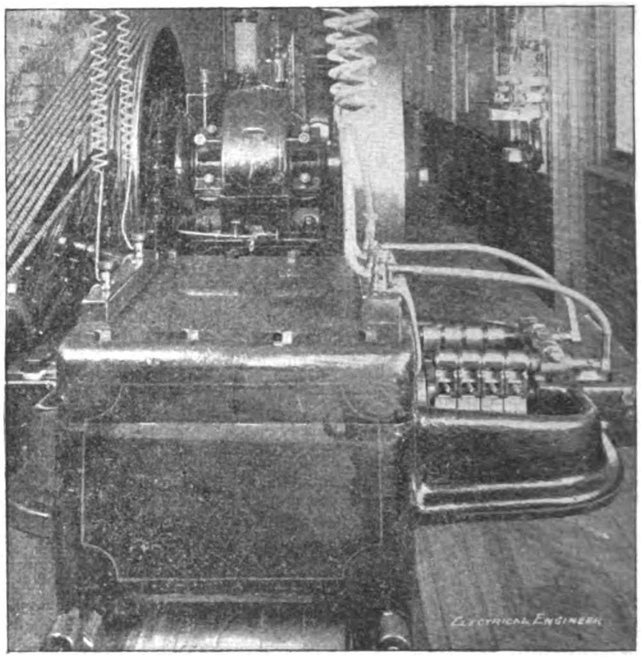

Fig. 2.—Rope Driven Dynamo Plant, Racquet Club, New York.

CIRCULATING BATTERY.

M. Serrin has recently brought out a continuous circulating battery, illustrated in *L'Electricien,* which is a simple sulphate of copper battery with zinc and carbon electrodes, but with a syphon arrangement for keeping up a continuous circulation. Two vessels, from and to which the liquid flows, are reversed every morning. The battery, it is claimed, has a low internal resistance, and is constant and economical.

THE FIRST MARINE LIGHTING PLANT.

An incandescent lighting plant said to be the first turned out of Edison's shops at Menlo Park will probably be on exhibition in the Electricity Building at the World's Fair. It is now used on board the steamer "Columbia," plying between San Francisco and Portland, Ore., where it was placed in Position in May, 1880. It has been in satisfactory operation ever since, with no alterations.

The first requisite of an observer is that his mind should be actively awakened to the phenomena of nature with which he is surrounded.—Joseph Henry.

THE LAMP SITUATION.

PROBABLY no one interested in any aspect of the case was surprised by the final outcome of the Edison and Sawyer-Man suit. We print elsewhere an abstract of the conclusion of the argument and the full text of the decision of the appellate court. The injunction granted against the Sawyer-Man Company will, of course, enable the General Electric Company to obtain similar injunctions against any or all other infringers of the second claim of the Edison patent, which is :

> The combination of carbon filaments with a receiver made entirely of glass and conductors passing through the glass and from which receiver the air is exhausted, for the purposes set forth.

The provision in the injunction order permitting application to the Court thereafter for the vacation, suspension or modification of the injunction, upon proof of the complainants' refusal to sell lamps to owners of plants installed before the Circuit Court sustained the patent (July 14, 1891,) will be regarded as some protection against the "unconscionable use" of the patent alleged to be intended by the General Electric Company. The right to attack the injunction in court would, we suppose, exist without this provision; but it is an advantage that this court announces in advance its readiness to entertain the application indicated. The court declined to investigate "upon the present case" the character of the combination forming the General company, for reasons stated fully in the decision.

The General Electric Company is thus put in full possession of all rights pertaining to the patent till its expiration a year or so from now. It remains to be seen just how it will use it, and with what effect upon the industry of electric lighting and upon the fortunes, particularly, of competing manufacturers. It should be, and we hope always will be, an occasion for congratulation, in itself, when a patent is sustained; although there must usually follow real or seeming hardship to somebody. In the present instance the hardship will be great and widespread, should the possession of the Edison patent prove a means by which the General company shall succeed in the purpose, so frequently attributed to it, of crushing out all competition, not merely in lamps, but in dynamos and all other electric lighting apparatus, and building up a control of electric lighting similar to that of telephony by the American Bell Company. We shall not undertake to read the minds of the president and directors of the General Company, nor that of their adviser, the distinguished and brilliant counsellor who brings to their service the experience derived from his connection with the Bell Telephone Company, and should know how to make the most of an adjudicated patent. If they press their legal right to the utmost limit, not only against infringing lamp makers, but, through their relations with lighting companies and the exaction of contracts that would shut such consumers out of the open market in the purchase of dynamos, accessory machinery and supplies,—whether or not such a course would bring them under the laws against the illegal restraint of trade—it would quite certainly enlarge and intensify the feeling of hostility and distrust toward the General Company now so prevalent among all who are in any way connected, directly or indirectly, with electric lighting. Can they afford, especially in view of the small period of life remaining to the Edison patent, to have every man's hand against them when the protection of that patent shall be withdrawn ?

Doubtless many lamp manufacturers, if unable to make terms for licenses, will soon be obliged to discontinue. Such of them as are suitably equipped will probably give their attention to making other apparatus until the expiration of the patent ; after which time a period of general competition in lamp making may be inaugurated. Meantime purchasers and the public are awaiting with interest the arrival upon the market of the non-infringing lamps promised by Mr. Westinghouse to be forthcoming January first.

THE INFLUENCE OF THE AIR ON ELECTRIC DISSIPATION.

THE description in our columns last week of the results obtained by Prof. Bjerknes in his experiments on the dissipation of electrical energy of the Hertz resonator has served to call forth an exceedingly interesting communication from Mr. Nikola Tesla, in which he details a number of facts and phenomena observed by him in his high frequency alternating work. Mr. Tesla, it will be noted, lays great stress on the influence of the air on the rate of electric dissipation with the currents here under consideration owing to its discontinuous nature, while he also explains thereby the observed difference between magnetic and non-magnetic metals as dissipators of electric energy. Mr. Tesla also points out some highly suggestive analogies between the rate of electric dissipation and that of dissipation by heat, fine wires in both cases being shown to have relatively greater powers in this respect. The mechanical action of the "electric sound-waves," observed by Mr. Tesla, is also of a decidedly interesting nature,

A DIFFERENTIAL WATTMETER FOR ALTERNATING CURRENTS.

BY

A. E. Kennelly

THE measurement of the efficiency of transformers is necessarily an important matter, for, setting aside the cost of the power that has to be expended in their excitation, wasteful transformers must, by undue heating, limit to a greater or less degree the output they could be made to yield with better materials or proportions.

The earlier and calorimetric tests of transformers[1] have been latterly almost entirely superseded by electrical wattmeter methods, which have themselves been tried in a variety of forms[2]. These instruments are capable of determining with all desirable precision the loss in transformers that are idle or that are worked on light loads. Although two such instruments, or two measurements with the same instrument, one for the energy absorbed, the other for the delivery, enable the efficiency to be determined at any load, yet when the readings of the instruments are large, they are well known to be less reliable, and the most recent advances have therefore been made in the direction of null methods, which Dr. Sumpner[3], and also Dr. Hopkinson[4] have used with excellent results.

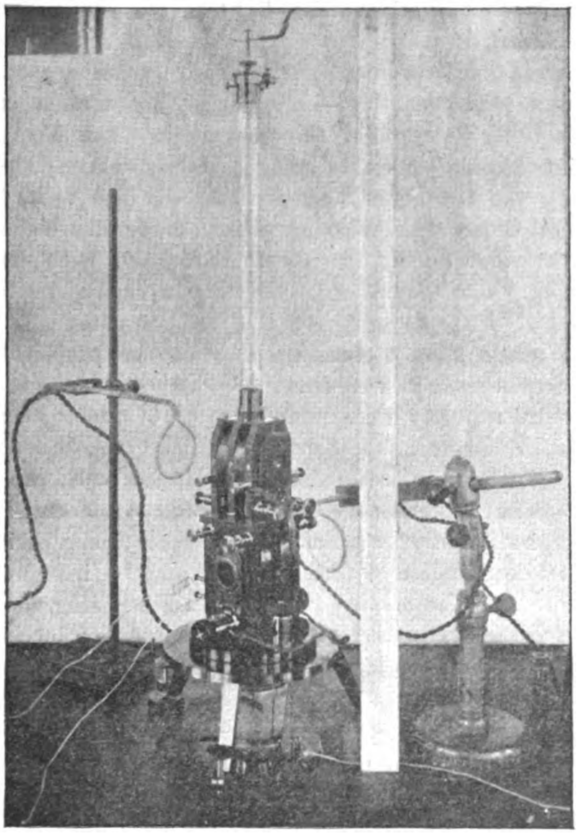

FIG. 1.—DIFFERENTIAL WATTMETER FOR ALTERNATING CURRENTS.

The object of this article is to describe a differential wattmeter that has been constructed and tested for the last nine months at the Edison Laboratory. This instrument is a double electrodynamometer of the Kohlrausch unifilar type and is reproduced from a photograph in the accompanying engraving, Fig. 1. These two dynamometers are arranged as wattmeters with their suspended coils rigidly connected by an aluminum shaft 8 cms. long. The upper wattmeter is in the primary circuit of the transformer to be tested, the lower in the secondary. The intake is therefore measured by the former, and the output by the latter, so that when the sensibilities of the two dynamometers are adjusted to equality, that is to say, when they are balanced differentially, the reading of the torsion head corresponds to the loss of power in the transformer due to all causes combined—hysteresis, c^2r, eddies, and radiation.

Thus assuming that the sensibility of each dynamometer was such that one degree of torsion represented an activity of five watts, and that they were independently inserted in the primary and secondary circuits of a 20 K. W. transformer worked at full load, the upper instrument would indicate, say, 20,750 watts with a torsion of 4,150 degrees, the lower 20,000 watts with a torsion of 4,000 degrees. Such a degree of sensibility would be of course quite impracticable, but mounted in combination with a common suspended system, the resultant torsion would only amount to 150 degrees. An uncertainty of 1 per cent. in the indications of the independent instruments would affect the results to a range of 207.5 + 200 or 407.5 watts. In the differential instrument, 1 per cent deviation at the same load would represent 1.5 watt error.

The framework of the instrument is entirely of hard rubber, supported by a stout brass tripod. To avoid frequent repetitions, we may denote the upper dynamometer's fixed coil by U, its suspended coil by *u*, and the corresponding coils of the lower dynamometer by L, and *l*, respectively.

In a differential instrument of this description, it is, of course, essential that U should have no effect on *l*, and likewise L none on *u*, so that the mutual inductance of these pairs of opposite coils must be negligibly small. This result is mainly accomplished by setting the two dynamometers at right angles in azimuth, but there is a residual mutual inductance, if only from the axial components of the coils which at this short range fail to be represented by simple solenoids. As this residual influence would introduce a very appreciable error at heavy loads, with the sensitive differential adjustment, it is necessary to eliminate it, and this is done by single turn auxiliary coils, set by trial outside the instrument, as shown in the engraving, in such a manner as to possess compensatory mutual inductance between L and *u*, U and *l*, but no appreciable additional inductance between L and *l*, U and *u*. All the leads to the instrument have to be carefully double wound to prevent external electromagnetic influence. There are four windings on L and also four on U, making eight pairs of binding posts in all for fixed coils, with two pairs of smaller binding posts for the connections with the suspended coils.

Coil.	No. of Turns.	No. of Layers.	Wire.	Resistance at 20 ohms C.	Inductance in millihenrys.
U 1	432	8	26 B.W.G.	7.11	5.44
U 2	120	4	22 "	0.934	0 588
U 3	28	2	15 "	0.0388	0.055
U 4	6	1	9 "	0.0028	0.023
L 1	120	4	19 "	0.36	0.389
L 2	28	2	18 "	0.22	0.052
L 3	4	1	strip 0.4" x 0.02"		
L 4	2	1	strip 0.875" x 0.02"		

The control of these eight coils in any combination gives the instrument a very wide range, and it can be used to test any transformer of the ordinary type up to 100 K. W. capacity.

The two small suspended coils are made of hard rubber and are similar. They have each an external diameter of 2.8 cms., internal 0.75, and an interflange of 0.96, wound with 675 turns in 27 layers of No. 33 B.W.G. with a resistance of 20 ohms, and an inductance of 6.6 millihenrys. Each coil weighs about 30 grammes, and the weight of the whole suspended system is about 65 grammes. Four connections have to be permanently maintained with this system, one through the torsion wire, one through the damping vane, and two by single loops of fine copper wire 0.002 inch, (0.005 cm.) passing under the base from opposite sides of the suspension rod of hard rubber to small binding posts. These loops are so flexible that they do not sensibly impair the oscillatory freedom of the system within the small limit of play allowed. The insulation of these fine wires is carefully preserved by carrying them up the suspension rod imbedded with wax in little grooves. This is essential, as 2,000 volts may be active between them. The suspension wire is of copper 32.6 cms. long, and 0.0115 cm. in diameter. Its torsional moment is 18.6 centimetre-dynes per radian of twist, and one complete revolution of the torsion head can be allowed without sensible elastic fatigue. The zero of the instrument is read by mirror, telescope, and scale. A slight directional force is provided by two loops of wire from the vane head to the sides of the damping vessel, which wire loops, maintaining electrical connection between the vane and base terminal, are straddled by small rider weights whose gravitational influence is sufficient to keep the zero definite. The vane itself swings in water covered with a layer of heavy oil, so that the oscillations are almost deadbeat.

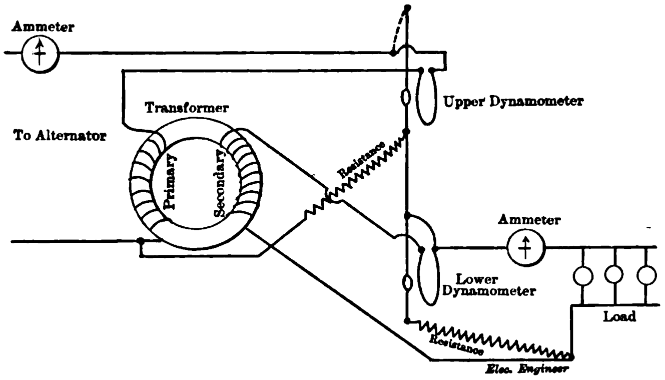

FIG. 2.

The transformer connections are indicated in Fig. 2. The compensation for mutual inductance between L *u* and U *l*, is first completed with each pair by trial. The two dynamometers are then balanced differentially. The fixed coils are connected in series and the suspended coils in parallel with suitable non-inductive resistances in their circuits and these resistances are adjusted until balance is obtained. For 1,000 volts of alternating primary pressure, 20,000 ohms is a good resistance for the primary suspension circuit, and in the secondary whatever may be necessary. For 100-volt secondaries, 4,000 ohms can usually be approximated to, making the $c^2\,r$ loss in this circuit about 2.5 watts. The value of the torsion readings is then found for either dynamometer by trial.

When the connections are made as in Fig. 2, and the secondary coil is open, the torsion needed to restore the zero is due to the upper dynamometer only, and measures the excitation loss. As the load is connected with the secondary, the torsion increases and measures the loss in the transformer plus the two or three watts absorbed in the circuit of *l*. If it is desired to analyze the loss due to hysteresis and eddies at each load, ammeter readings must be taken in both primary and secondary circuits, and in any case voltmeter and ammeter readings are required in the secondary circuit to determine the out-put. From this out-put and the observed loss in the transformer, the efficiency can be immediately deduced. It is easy to show that with such an instrument, the results are not influenced by the shape of the waves of E. M. F. generated by the alternator, and that the error due to lag in the suspended coil circuits is quite negligible when proper non-inductive resistances are employed.

The following is a specimen table of observations on a particular transformer. The calibration was so adjusted that each degree of torsion represented one watt. It will be seen that the loss due to hysteresis and eddies combined is practically constant throughout. In a few instances, tests of transformers whose magnetic leakage has been considerable, have shown an apparent decrease in excitation loss between idleness and full load, but amounting to only three per cent.

In this case the wattmeter was differentially balanced after compensation for mutual inductance and carefully adjusted.

Balance 19,480 ohms in primary suspension circuit.
3,735 " " secondary " "

These resistances were of bare german silver wire, non-inductively wound on insulating grids. The compensation and balance were checked after test.

ORNAMENTAL LAMP POSTS IN GERMANY.

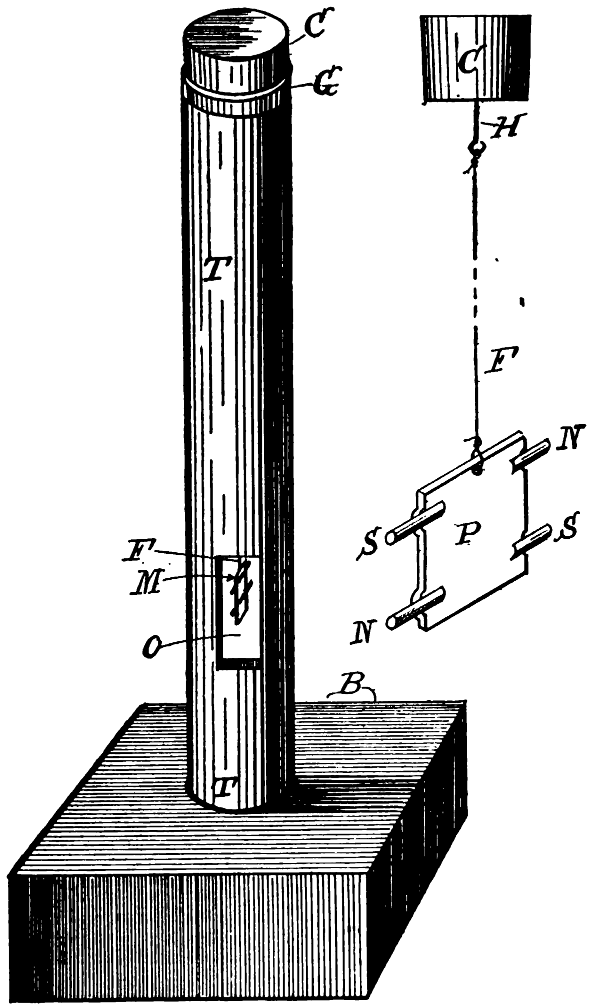
A BERLIN, Germany, reader of THE ELECTRICAL ENGINEER writes: "Your article on the Fifth avenue arc lighting from incandescent circuits interests me. It is the best indication of the new tendency in American cities towards the use of neat and even beautiful electric lamp supports, such as one may see in so many European cities. As this system is referred to by you as new and patentable, it may be of interest to you to know that the same arrangement has been in use in Hamburg about two years. I saw it erected; saw the man trim the lamps frequently; and always admired it as a practical affair. It is in a group of lamps around the Alster. Most of the lamps hang on separate ornamental house arms, or are placed on candelabras; but in this case, at the head of the Neuerwall two were placed on the same pole with two arms similar to that shown in the ENGINEER, and with the rheostat in the base as in all the other Hamburg street lamps. The installation was made by the Hamburg City Electrical Works, under the superintendence of Mr. Von Geisberg."

A SIMPLE MAGNETIC DETECTOR.

BY

James Bowstead Williams M.D.

In the course of a physician's practice he is often called upon to determine whether or not a piece of a needle or tack has become embedded in the body of his patient. If he is consulted immediately after the injury has been received, it is generally a simple matter to locate the metal, and remove it. But if several weeks have elapsed since the real or supposed insertion of the metal, it is a very difficult thing not only to decide whether metal is present in the body, but also to ascertain its location; for it is a well-known fact that a piece of a needle, and sometimes a whole needle will often travel a considerable distance in one of the limbs. The writer was once called in consultation in a case where the history and symptoms strongly indicated that a piece of a carpet-tack had entered the foot of an adult and lodged there some weeks previously. As some kind of magnetic device was indispensable, in order to effect a diagnosis, the writer made the simple but effective detector which is here shown and described. Its use demonstrated the fact that the symptoms were not caused by a piece of iron, and the favorable termination of the case proved that the indications of the detector were correct. The detector consists, essentially, of an astatic combination of magnets suspended by a cocoon fibre in a tube, which will protect the suspended device from the effects of electrical charges and air currents.



SIMPLE MAGNETIC DETECTOR.

The tube T, is a piece of clear glass tubing, the inner and outer surfaces of which are entirely covered with tinfoil, except the two openings, O, through which the movements of the magnets can be seen. The tinfoil can be secured to the glass by mucilage. Both layers of foil must be brought together at the bottom of the tube and cemented to each other, so that the two layers practically form one sheet of foil. Unless this is done the glass will become electrified by friction, and the action of the magnets thus rendered uncertain. The tube is fastened in any suitable base, such as a block of wood, B. The magnets, SN and NS, are made by taking two short pieces of needles or steel wire of the same length and diameter, making their ends true, and then magnetizing them. They are then fastened in a piece of stiff paper, P, as shown, with their poles reversed, and should lie in the same vertical plane. Care and knowledge of the art of magnetizing are requisite in order that the combination, when suspended in the tube by the fibre F, shall *just* point north and south, and yet be caused to deviate from this line by bringing a piece of iron or steel not more than ½ of an inch long within about 6 inches of the tube. If the magnets should have the same strength, and have their magnetic axes in the same vertical plane—things which rarely occur in practice—the combination will point east and west, as happened with the first set made by the writer. When this occurs the strength of one of the magnets must be very slightly diminished, and the combination again tested while in the tube. The paper to which the magnets are attached must be thoroughly dried, and then varnished, before it is used, and the suspended device must be well balanced, and be as light as possible. A cork, C, closes the upper end of the tube, and has fastened to it a wire hook, H, to which the upper end of the silk fibre is secured.

Before using the detector, see that *all* articles containing iron or steel, such as knives, keys, and wearing apparel, are removed at least three feet away from where it is to be placed, and that they remain stationary. Place the detector on any steady support, with the openings in the foil (which should be as small as possible) and magnets in a north and south line. Then move the member supposed to contain the metal about the tube in different directions, without touching it, however, and if any iron or steel approaches within about six inches of the tube the needles will surely move, provided that the apparatus has been properly made and adjusted.

TELEPHONE SUBWAYS FOR JERSEY CITY.

THE NEW JERSEY STATE ELECTRICAL SUBWAY COMMISSION has adopted resolutions giving subway privileges to the New York and New Jersey Telephone Co., in Jersey City. The subway commissioners have directed that creosoted wood or other suitable material be used in the construction of the conduits. The conduits must be 18 inches under the surface of the street, not less than one foot outside of the curb line and the same not more than three feet in width and six in depth. All manholes must be kept below the surface of the street. The conduits must all be used for the operation of the police and fire lines unless they should obstruct the wires of the company used for its own business.

A CENSUS OF CARRIER PIGEONS.

THE French Minister of War has ordered a census to be taken of all the pigeons in France, that would be available for carrying dispatches in time of war. They are all to be numbered; those attached to the military establishments, those which belong to pigeon flying associations and clubs, those that are the property of the farmers and landowners. Thoughts of pie must be banished now that the pigeons are of national importance.

ELECTRIC RAILWAY DEPARTMENT.

IRISH'S CLOSED CONDUIT FOR ELECTRIC RAILWAYS.

BY

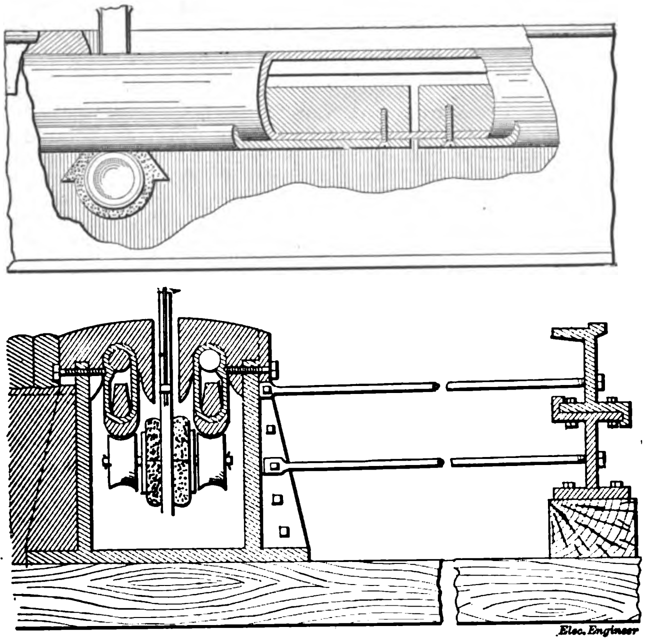
W. E. Irish

In this system, which is an improvement on the writer's previous work in this field, the conductor is completely enclosed and held rigidly in an insulating, elastic, water and dust-tight tube about one inch in diameter. The circuit is opened and closed by the pressure, or release from pressure of the trolley on the walls of the elastic tube. The trolley travels with an elastic pressure against a sectional rail composed of circuit-closing pieces secured to the outside of the flexible tube. These sectional rails are connected by means of screws through the walls of the elastic tube to similar sectional pieces within the tube, thereby forming pairs, each pair being insulated from the next by a space so that the rubber tubing intervening forms a flexible hinge between them and permits of their being independently raised in contact with the feed or trolley wire.

The interior contact pieces are normally separated by their weight and by the elasticity of the tube from the supply wire, until the arrival of the car, when the pressure of the trolley against the sectional rail, compresses the walls of the tube until the interior sections touch the supply wire, by which action the circuit is closed.

As the trolley advances, each sectional pair as passed, will spring away from the conductor. but not before other sectional pieces or pairs have been forced in contact so as to maintain the circuit closed ; there is, therefore, no sparking at the trolley.

The mechanical construction of the conduit is clearly illustrated in the cross-section, Fig. 1, which shows the conduit, trolley and sectional conductors with the circuit open and the trolley out of action. In Fig. 2 the wall of the conduit is broken away showing the trolley, elastic tube, and outer sectional conductor. The wall of the rubber tube is also broken away to show the conductor and interior sectional conductors, which are out of contact with the supply conductor.

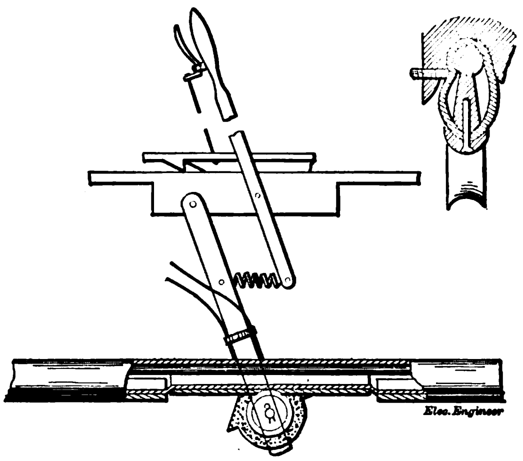


Figs. 1 & 2.—Irish's Closed Conduit for Electric Railways.

Fig. 3 shows a double trolley in action and pressing sectional pairs against the conductor.

Fig. 4 shows a cross section of the elastic tube, conductor, and sectional pair, in position when the circuit is closed.

From the engravings it will be understood that the supply conductor is rigidly fixed and located in the upper part of the elastic tube, while sectional conductors are located in the lower part where they are connected through the walls of the tube to exterior sectional conductors, of the same length, by screws. Normally the sectional conductors are not in contact with the main conductor but they touch when the trolley presses against them, because the tube is flexible. The conductors are retained in place by screws, which force rubber plugs against the flexible tube, and conductor, and clamp them in position against the wall of the recess, which is provided for the tube and conductor, in the cover of the conduit. The flexible tube is closed at intervals so that should it become injured and expose, at any point, the conductor, water or moisture could only enter the section injured.



Figs. 3 & 4.—Irish's Closed Conduit for Electric Railways.

The trolley is carried on a pivoted lever under the car, and is connected to the hand lever by a spring, which insures, when the trolley is active, a flexible pressure of the trolley against the sectional conductor. Thus, when the handle is operated and the trolley is moved along the conduit, it raises the sectional conductors until they come in contact with the main conductor, when the circuit will be established from the conductor to the trolley and thence to the motor and back by the second trolley; or, when only one trolley is used, by the conduit and rails. The trolley may be released, so as to open the circuit instantly, by pressing either by the foot, on the tread trip, or by the hand, on the hand trip.

With a good rubber tube the cost estimated will compare favorably with that of the trolley system.

This system possesses the advantages among many others of being absolutely free from danger to life or property, and of involving no loss of current by leakage.

The rubber tube, contained as it is in a damp dark chamber where it is not subject to extreme or sudden changes of temperature would last many years without the least deterioration.

The conduit measures about fifteen inches deep and seven inches across the exposed part of the cover. The conduit and the rails are adjustable one with the other by the ties, so that if by any chance the slot should get out of alignment, it can be easily and readily readjusted.

The conduit is cleaned, as found necessary, by trailing a scraper through it; the scraper as it collects the dirt, etc., dumps the same at the manholes, placed at frequent intervals, as it passes. From these the dirt can be removed as occasion requires.

ELECTRIC TRACTION BETWEEN MINNEAPOLIS AND ST. PAUL.

The success of the electric trolley road between St. Paul and Minneapolis, is so pronounced that the short line service over the steam railroad has been abandoned, only the regular through trains now taking such passengers as may wish to travel the 10 miles in that way at the higher rate of fare.

THE WYNNE SYSTEM OF ELECTRIC TRACTION.[1]

Our readers will remember an accont upon the Wynne tramway system, which we printed some time since.

The leading feature of this system is that only those sections actually covered by the moving car are connected with the buried conductor. The sections are 5 feet long, and five at least are always covered by the car; they are laid on asphalt concrete, and are run in with bitumen, which affords tolerable insulation between the sections and from the earth. These sections are charged in pairs as the car moves over them. Mr. Wynne has recently modified the details of his system, and by placing the contact boxes between two sections, he is able to reduce the number of magnetic switches while retaining the important principle that only those sections which are under the car and its platforms are charged. The contact boxes are placed at intervals of 10 feet, and their covers constructed on the diving-bell principle. The connections are easily accessible, and the contacts may be quickly replaced. A part of the line in Fig. 1 shows a contact box with portions of the crenellated rails.

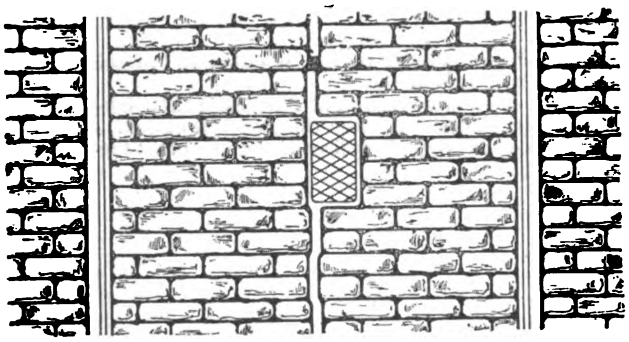


Fig. 1.—Part of Track Showing Tram Lines, Mid-Rail, and Contact Box.

In Fig. 2 two sections and a plan of the contact boxes are shown, together with a section of the mid-rail, showing the buried conductor. This conductor is led into the box and the two ends are brought up and sweated to a double shoe from which the current is tapped off. This shoe is a single casting, and consists of two ferrules united by a cross piece. The ends of the conductor sections are turned up and enter these ferrules, one of which is shown in the side elevation of the contact box. A pair of split contact springs are provided, and the shoe is connected to the lower one. Two tubular magnets A and B are mounted in the box, one vertically and the other horizontally to save space. Two insulated wires are connected to the upper contact spring. One goes to one magnet and thence to the cast iron case of the box, putting it in connection with one section of contact rail. The second wire goes to the other magnet, and thence runs alongside the main conductor for a short distance back along the line to the next section of the contact rail. A double armature, C C, carries a copper contact wedge, D, which is thrust between the contact springs when either or both of the magnets are excited.

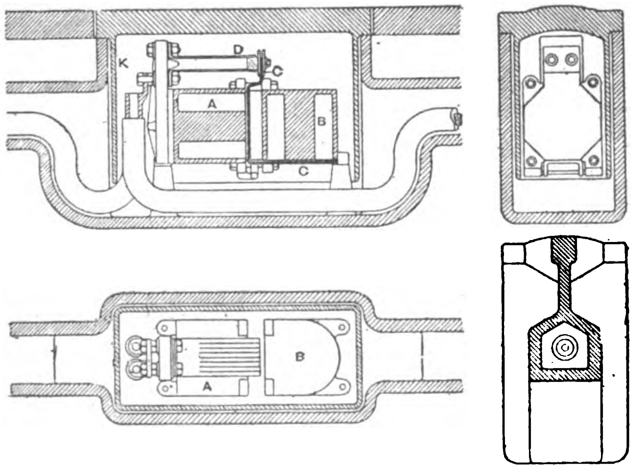

Fig. 2.—Details of Contact Box and Section of Mid-Rail.

A diagrammatic view of the system is given in Fig. 3, where seven sections or parts of sections of the mid-rail are shown, lettered A, B, C, etc. The sections A and B are not yet connected with the buried conductor; C and D are so connected, and E and F are just about to be cut out. When this is done the armatures fall back by gravity. The contact between the conductor and the section F is maintained by the magnet in series with section E. The current passes from the brushes through the motor, and thence by the wheels and rails to earth. In the event of the breaking of the circuit, the contacts in the boxes fall open. To enable connection to be re-made two or three secondary batteries are carried on the car, and being arranged with a small resistance of about ¼ ohm, as shown in Fig. 3, are kept always charged.

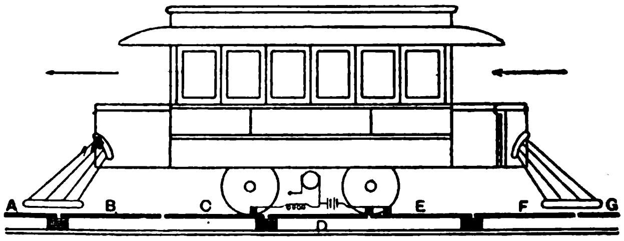

Fig. 3.—General Arrangement of Wynne System and Diagram of Connections.

HOW SHALL ELECTRIC RAILWAYS BE TESTED?

BY

E. A. Porter.

I have read with interest the test of the Biddeford and Saco Railway Company's plant, but ask permission to make some remarks on the same.

The cost of coal per car mile may be a good standard for the comparison of the entire plants (station, cars, track and feeders) of different street railway companies, but it is of little value in the comparison of the efficiencies of power stations.

A far better standard for comparing the efficiencies of different power stations is the *number of pounds of coal per electrical horse power per hour* and the best standard for comparing the efficiencies of the engines, shafting, belting, and dynamos of different stations is the *nnmber of pounds of water per electrical horse power per hour.*

In the test of the Biddeford and Saco Railway Company's plant as given in your issue of Nov. 23, 1892, the mean electrical horse power is 50, the number of pounds of water evaporated is 45,300, making 906 pounds of water per electrical horse power per day. Assuming that the length of the run was 20 hours we have 45.3 pounds of water per electrical horse power per hour; a result below that obtained in Cleveland as given in The Electrical Engineer of March 9, and April 27, 1892.

AN EMERGENCY TELEPHONE FOR ELECTRIC RAILWAYS.

An ingenious method of preventing delays on electric railway lines by affording immediate communication with the central station in case of an accident on any part of the road, is in operation upon the Port Defiance, Tacoma & Edison Railway. Connecting wires from a telephone pole line, along the track, extend down the poles to within a convenient distance from the ground. Each car carries a telephone outfit which can thus be readily attached to the line at any point and the trouble at once be reported to headquarters. Orders can then be received for the operation of the cars on either side of the break.

THE DEADLY ASH CART.

The other night an intoxicated man tried to board a moving electric car down town and fell, and narrowly escaped being run over by an ash cart that was coming in the rear. The deadly trolley must go.—*Reading Telegram.*

Connecticut.—It is stated that there are now 41 electric railway franchises asked for to be brought before the Legislature. Many of these are competitive and some will not be granted, but the residue will create a brisk demand in Connecticut for electric railway material.

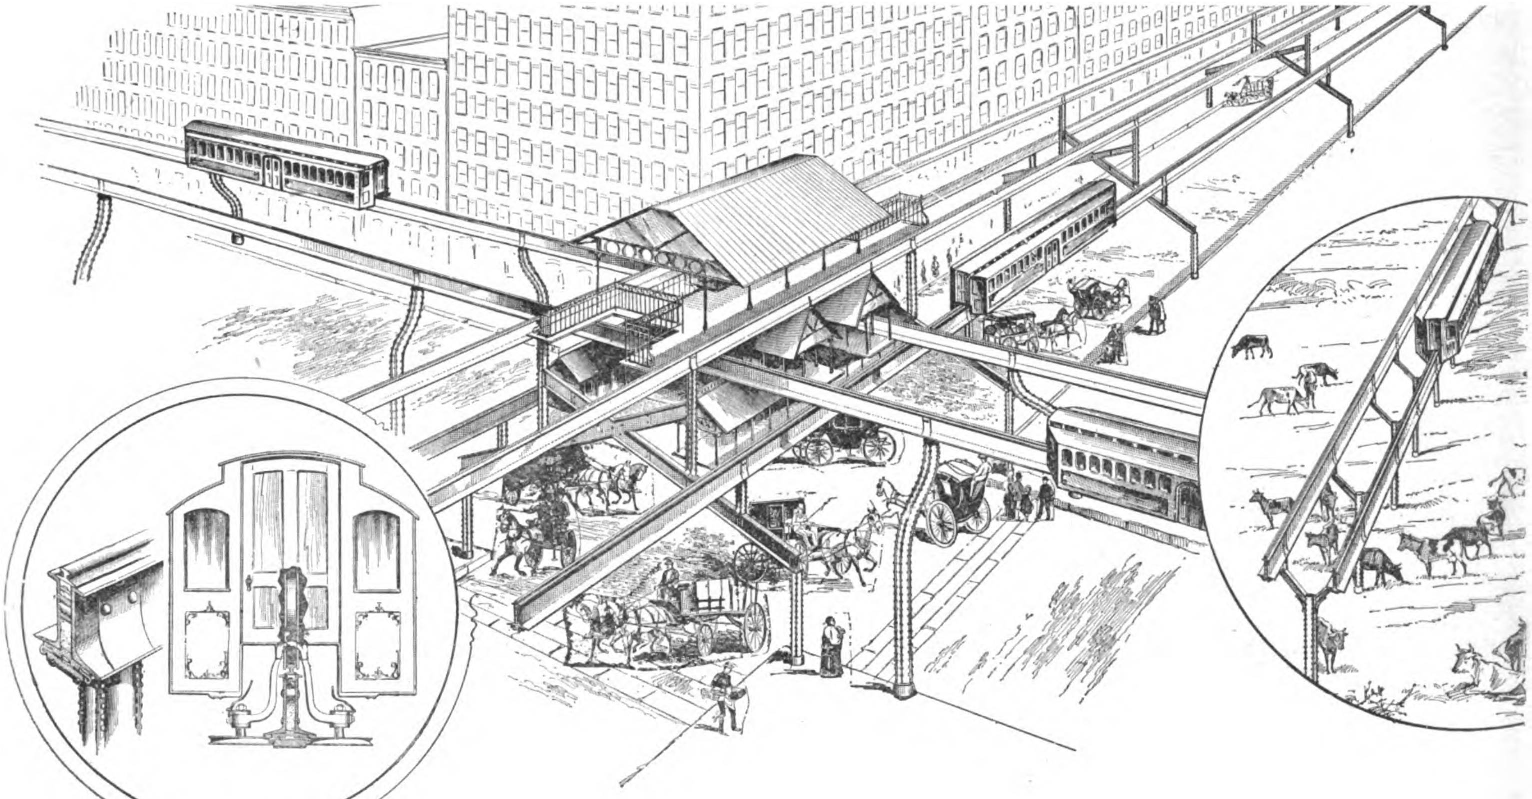
THE NEW "PRUYNWAY".

Rapid transit in cities has claimed the attention of engineers for many years, and judging from the present indications will continue to do so for a long time to come. With the electric motor available as a propelling agent the problem is vastly simplified and this fact has been taken advantage of by not a few engineers.

Among the recent attempts in this direction is that of Mr. Henry S. Pruyn, and our readers will be able to gain a good idea of his proposed method from the accompanying engravings.

The panel at the left gives a perspective view of the structure of the girder and of the rail which it carries on top of it and the two current-conductors carried under the lower flange, where they are not only insulated, but absolutely protected from damage by the weather or any other cause. Slightly below the level of these power current-conductors and between them and below the structure, is a space for telegraph, telephone, electric light and other electric lines which are also protected from interruption by snow, ice or other causes. As these conductors are firmly fastened and completely protected, there is no danger of short circuiting or leakage of the current.

In the Pruyn method of operating the electric power and current, the system does not depend upon the ordinary ground circuit. Instead of the return current being allowed to pass through the structure to the ground, it is passed from the generators stationed at suitable intervals along or under the railway line, out through the conductor at one side of the structure, and picked up and carried by a suitable truck-conductor to the car motor, and after having performed its work in driving the carrying-wheel which rests on the top of the main rail, passes down on the other side of the car, through a suitable conductor, into the opposite guide-wheel below, which delivers it to the current-conductor on that side and returns it to the original generating station where it again passes through the generating dynamo and out again to the line. The current makes a complete circuit. Thus, the electrical system is self-contained.



The New "Pruynway."

This arrangement not only results in economy of power, and prevents short circuits, but provides against induction from the heavy power-conductors used for propelling the cars, upon the telegraph and other conductors adjacent, as well as to all contiguous electrical lines whether included in the railway structure or not.

Again, atmospheric conditions have no effect on the electrical conductors contained in the Pruynway structure or supported by it, since the charge goes directly to ground through the structure.

The end elevation of one of the cars shows the car truck. At the top of the truck is seen one of the carrying wheels resting on the track rail, while at the bottom of the truck are seen the pair of guide wheels picking up the current from the conductor under one side of the structure while the other guide wheel returns it through the conductor on the other side, after having passed through the motor.

Each car is self-propelling and the cars may be run singly or in trains. The weight of the car and its load is carried low on either side of the track rail, and largely below it. The strengthening frame-work of the car is in the floor and a large proportion of weight in addition to this strengthening frame is in the low-hanging trucks of which there are two for each car. The carrying wheels bear the car by means of heavy pins with spring bearings on which the weight of the car rests. The carrying wheels run on and pass curves without the grinding action inseparable from the ordinary car truck which of necessity passes over a greater distance on curves with its outer wheels than with its inner wheels, compelling one or both wheels to have more or less sliding friction according to the abruptness of the curve.

Owing to the form of the railway and of its supporting the cars, the car floor is run about 10 feet lower or nearer the earth's surface than in ordinary elevated railways, while preserving an equal amount of clearance beneath the girder. This saves from 15 to 20 stairs in ascending to the stations.

The central view in the accompanying engraving shows the system as applied in cities, with a three-story station at the intersection of two streets, for the accommodation of passengers on either of the three lines of railway shown. Through express cars run on the two highest tracks of the main line; local accommodation cars run on the lowest pair of tracks nearly over the curbs on each side of the street. Cross-town cars run on the pair of tracks at a level half-way between the respective levels of the express tracks and the accommodation tracks running up and down town.

The view on the right hand will give an idea of the Pruyn method of construction for a cross-country, double-track road. A right of way, one rod wide, is sufficient for it. There are no grade crossings for wagon roads, foot-paths or railways, and thus no liability of damage to persons or property from passing trains, smoke, or accidental fires from locomotive sparks.

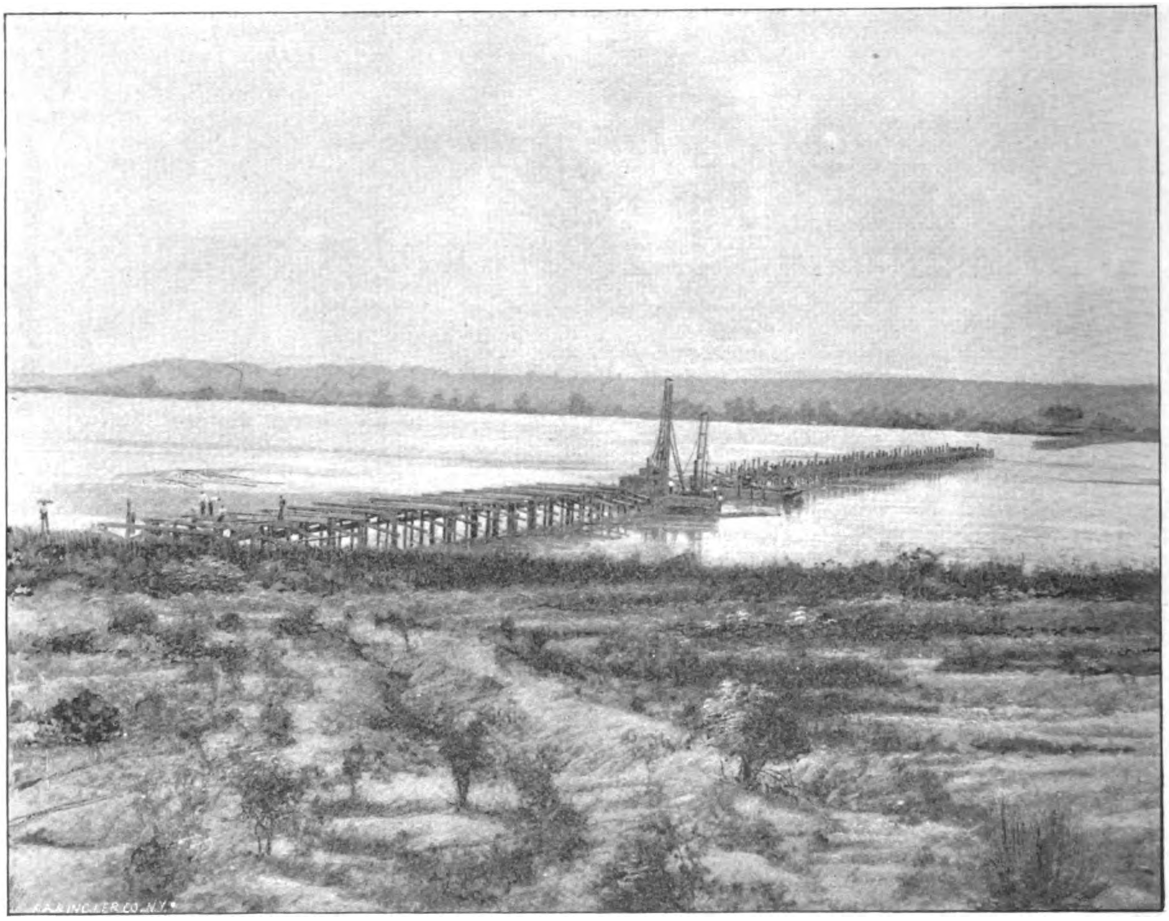
This system which is the invention of Mr. Henry S. Pruyn, 421 Rialto Building, Chicago, is now being exploited and Mr. Pruyn hopes to make a practical demonstration of its feasibility at an early day.

THE WASHINGTON, ALEXANDRIA AND MOUNT VERNON ELECTRIC RAILWAY.

THE operation of cars on a railway 10½ miles long, exactly two months after the contract was signed, which was accomplished by Mr. Charles H. Davis, C. E., of this city, as chief engineer of the Washington, Alexandria and Mount Vernon Electric Railway, is a feat almost, if not quite, unique, in the history of electric traction.

Ground was broken on June 18, the day on which the contract was made with the Mount Vernon Construction Company; steam was raised on September 15, and the road was opened three days later.

The accompanying illustration shows the trestle and draw bridge over Hunting Creek during process of construction. The trestle is 4,000 feet long and the draw has a span of 100 feet. The latter is built of plate girder and rests on a centre pier of iron and concrete. The rails are 50-pound T and 55-pound Wharton girder, and 900 28-foot poles with 10-inch butts and 7-inch tops support the trolley wires. Two 16-foot Brill cars, equipped with Thomson-Houston motors, are in use and make from 25 to 30 miles an hour.



CONSTRUCTING THE TRESTLE AND DRAW, W. A. & MT. V. ELECTRIC RAILWAY.

The power house is 92 feet long by 68 feet wide, and contains two Edison generators of 200 h. p. each, belted to two 200 h. p. Green engines, with 16 x 36 inch cylinders. The boilers are two in number, of 150 h. p. each, and were built by the Harrisburg Foundry and Machine Company.

Mr. Bertram P. Flint was the engineer in charge of the construction.

ELECTRIC RAILWAY ACCIDENTS—DECISION CONCERNING NEGLIGENCE OF PASSENGERS.

THE full bench of the Massachusetts Supreme Court, at Boston, on December 14, rendered a decision on a new point of law in the Albert E. Beal *versus* the Lowell and Dracut Street Railway Company. The plaintiff was riding on the front platform of an electric car, and was thrown to the ground in an accident caused by a defective switch. The court overrules the exceptions, and sustains the decision of the lower court which found the plaintiff guilty of negligence, because there attend the employment of electricity the same dangers that might attend the employment of steam; while it is not necessarily negligence for a passenger to ride on the front platform of a horse car while in motion.

UNDERGROUND ORDINANCE IN CLEVELAND.

THE underground ordinance has once more risen to the surface, and from present indications it is soon to be enforced. The city electrician, Mr. Geo. Hoag, has ordered the removal of the network of wires, which at present adorn the City Hall and these will be placed temporarily upon poles. There is a strong appeal from the Board of Trade, the Board of Underwriters and the Fire Department, for the removal of all overhead wires and the scheme at present is for the city to build and own the conduits and fix the rental at a price simply necessary to maintain the system. The local telephone company has opened war against the electric roads in their use of a ground return, advocating in its place a double trolley system. It instances the evil electrolytic effect upon the gas and water mains, as given in the report of Mr. Morse, Supt. of Telegraph, of Cambridge, Mass., and also cites the experience of the West End road in Boston.

CLEVELAND NOTES.

NEW ELECTRIC ROAD.—The City Council of Cleveland, at its last meeting, gave an unconditional franchise to the Cleveland City Cable Railway Co., permitting them to equip their St. Clair road, the last of the horse lines in Cleveland, with electricity. The franchise was so worded that the Company also have the privilege to change their cable road over to the trolley system, of which privilege they are sure to avail themselves at the earliest possible opportunity. At the same meeting, the council received from two local societies, both being strong advocates of municipal ownership of the telegraph, telephone, etc., resolutions to the effect that the city build and operate a belt line around the city, connecting Wade and Gordon Parks.

The council nodded its approval by passing a similar resolution and referring it to the Director of Law, to see if there were any legal obstacle in the way.

LEGAL NOTES.

THE EDISON-SAWYER-MAN LAMP CASE—II.

EDISON ELECTRIC LIGHT COMPANY AND EDISON GENERAL ELECTRIC COMPANY *vs.* SAWYER-MAN ELECTRIC COMPANY. FINAL HEARING BEFORE THE UNITED STATES CIRCUIT COURT OF APPEALS.

MR. ROOT, continuing for the defendant (appellant), said that combinations like the General Electric Company had been repeatedly denounced by the courts, both state and federal, as being in contravention of common law and contrary to public policy. He then cited a list of cases sustaining his view. The form or method adopted to effect the combination was of no consequence. No form leaving the parties combining still in existence and owning their own property had ever escaped the condemnation of the court when such combination was to secure a monopoly and in restriction of competition. He cited the cases of the Sugar Trust (54 Hun. 354): the State of Ohio *vs.* The Standard Oil Company (30 N. E. Rep. 279), and American Biscuit Company *vs.* Klotz, in the Circuit Court of the United States for the eastern district of Louisiana (44 Fed. Rep. 721). In the latter case the court had gone so far as to hold that where a corporation had been organized for the purpose of combining a large number of bakeries, and had actually purchased their property, that arrangement, because of its effect at large, was such as to justify the court in refusing to grant a receiver *pendente lite* upon the ground that the purpose of the complainant was such that a court of equity ought not to give it any assistance. After further citation of cases, and further argument upon this aspect of the case, Mr. Root dwelt upon the inter-relations of the Edison Company, the Thomson-Houston Company and the Westinghouse Company, claiming that an injunction would assist the General Company to substitute Thomson-Houston alternating apparatus for Westinghouse apparatus in many plants throughout the country, and that, as the Westinghouse Company was under contract not to sell any incandescent lamps to users of the Thomson-Houston apparatus, the early expiration of the Edison patent would leave the Westinghouse Company under the disadvantage of inability to supply lamps to plants originally equipped with their own apparatus, so long as their contract with the Thomson-Houston Company remained in force.

Mr. Lowrey, for the complainants (appellees) followed Mr. Root and devoted his argument mainly to the consideration of the equities and inequities alleged on either side. He pointed out that the combination, so eloquently complained of by Mr. Root, had been made after Judge Wallace told the world that they must not make Mr. Edison's lamps, that it was unlawful to do so. At the time of Judge Wallace's decision the complainants had been seeking an injunction to stop the Thomson-Houston Company from manufacturing those lamps. Were they forbidden to settle out of court with a party willing to be settled with? The combination had simply brought in a recalcitrant and rebelling party. Counsel on the other side might ask what was to be the policy of the General Company, and what it would do in respect to selling lamps to persons holding Westinghouse apparatus. Mr. Lowrey would repeat, in substance, what was answered in their brief on that point, namely, that he did not suppose any man living could answer that question. It was quite improbable that any policy could be resolved upon which would take into consideration so large and so complicated a mass of business, in which, in this city, there was an Edison licensee claiming a right against a licensee of the Thomson-Houston Company and against a licensee of the Westinghouse Company, all three of whom the General Company desired to make its friends, to secure their business, to establish relations which would enable them to go on harmoniously, and to reduce the injury to any one of them to a minimum. To accomplish this was a work almost of statesmanship; no Board of Directors, much less any drummer out West, could undertake to say what would be or what ought to be the policy of the General Company. If their Honors were wiser than all the Judges who have ever sat and if they possessed all the practical acumen which business men own, they could not announce at this time about this business any safe, judicious, and fair rule than that the whole matter will have to be dealt with fairly and upon business principles, giving to each case its proper consideration as it arises.

In respect to the affidavits charging the complainants with an intention to make an oppressive use of the injunction—that is to say, refuse to sell to somebody—Mr. Lowrey was authorized to say that it was not the intention of the General Company, or of the complainants, to refuse to sell lamps for use on Westinghouse machines. They desired to sell their lamps everywhere, had put them in the hands of supply dealers for sale and did not intend to take them out of the supply dealers' hands; anybody who wanted to buy them would continue to find them there, and there was not a thing in this case indicating the contrary.

In respect to the right of complainants to the injunction, counsel maintained that since Congress passed the first patent law an injunction had never been refused a patentee whose rights had been juducially settled out and out; the cases, he believed, sustained this proposition absolutely. This court was now asked to take a new step, and for the first time to restrain a manufacturer, whose right was clear, at the suit of a manufacturer whose infringement had been proven.

In respect to the argument of the other side upon "public convenience", Mr. Lowrey claimed that the people who would be inconvenienced were in no proper sense "the public"—not the "public public"—it was a "private public"—it was a public engaged in the business of using lamps for their own convenience, in factories and elsewhere—quite different from that public whose rights were common and indistinguishable in the streets and such places. It was nothing but a very extended and enlarged number of minor and subordinate infringers.

THE COURT (Judge Wallace)—Does it make any difference whether the lamps are located in the streets or inside of houses or factories?

MR. LOWREY—I do not think so; but I am trying to deal with my friend's effort to raise up a phantom public.

THE COURT (Judge Wallace)—It is just as much a public use if these lamps are used in factories or in private dwellings as if they were used on the streets. They are used in the same places that water and gas are used in.

Continuing his address, and passing in review further points relating to public convenience and to the alleged intention to withhold the sale of lamps to Westinghouse users, Mr. Lowrey made an appeal in behalf of the Edison licensees, who had been waiting many years for rights hitherto denied them. When they heard the recent judgment of this Court they thought the time had come at last when they should receive that for which they had bargained and paid. He would ask the Court in looking at users, to think of those users who had obeyed the law, who had paid great sums, and who were now waiting to see whether there was anything in it when a man wins a big patent case.

Mr. Seward followed Mr. Lowrey, closing the argument for the complainants. Touching somewhat on points gone over by Mr. Lowrey, and in the United States Company case, he gave attention chiefly to that part of the defence based upon state and federal legislation against monopolies and restraint of trade and upon common law doctrine in these regards. After contending that the combination—the General Electric Company—was entirely a legal one, he claimed that even if it were illegal, the present case would be within the familiar principle of law, referred to by Mr. Lowrey, that the test of whether the illegality prevented recovery was whether the plaintiff must trace title through the illegality in order to reach the parties. The complainants were not the General Electric Company, nor did they trace title to the patent through that company.

Referring to the anti-monopoly and anti-trust aspect of the case, Mr. Seward said that the Court had nothing before it to show that the General Electric Company, if it were the plaintiff upon the record, was doing anything forbidden by law. No evidence was given of any contract, or of any act, tending to show that complainants or the General Company were striving to effect an illegal restraint of trade or to create an illegal monopoly. It appeared from the papers in the case that every company controlled by the General Company had been formed for the production of patented articles; some to make lamps, others to make dynamos, etc. The monopoly would therefore be wholly based upon patents—a legal and recognized monopoly.

MR. WETMORE closed the case for the defendant (appellants). He began by asking what would be the irreparable injury if the preliminary injunction were vacated during the pending of the suit and the defendant were permitted to supply lamps to Westinghouse users meantime. Was the preliminary measure which might be recovered for the infringement during the pending of the suit made inadequate or insufficient?

After argument on the point of estoppel on account of the well-known relations of the Thomson-Houston, Sawyer-Man, Consolidated and Westinghouse Companies, Mr. Wetmore proceeded to urge that under no circumstances were the complainants entitled to an injunction which would be free from the condition that they supply the users of Westinghouse apparatus to meet the orders of defendant upon reasonable terms. Counsel on the other side urged that the complainants did not intend to refuse to sell the defendant lamps.

THE COURT (Judge Lacombe)—They do not exactly say that. I do not understand that they dispute the fact that they do not intend to sell lamps to the defendant, the Sawyer-Man Co.. What they say is they do not intend to refuse to sell lamps to the users of the plants that are established. I do not understand that there is any statement on their part that they expect to sell lamps to the Sawyer-Man Company.

Mr. Wetmore continued arguing in favor of a restriction or modification of the injunction which would compel the complainants to sell lamps to Westinghouse users upon reasonable terms. That was the condition which he thought should be put into any injunction that should be granted. There was no difficulty about that. Every man knew whether terms were reasonable or unreasonable. In case of controversy they could go to the court and determine whether or not there was a breach of that condition.

But, to make a distinction now and say that they could fill orders directly to customers, but that the Westinghouse Company could not give an order, was just the thing that would cripple the Westinghouse Company and prevent its continuance in business. That company was obliged, in carrying on its business, to furnish central stations with apparatus. Perhaps the meaning of the complainants was that the Westinghouse Company must not build any more plants, that they must suffer for the plants already built, and that they must go out of the business in the future.

THE COURT (Judge Lacombe)—I understand that to be the claim.

Mr. Wetmore said that it would then, of course, be idle to talk about the past if they could impose upon the defendant a condition which would drive the Westinghouse Company out of business, by laying their hands upon one single branch of it. Was that equity? Was that necessary?

Judge Wallace asked Mr. Wetmore: "What right have you to complain of that? You entered upon this enterprise with a knowledge of this patent; as business men you took the chances." Mr. Wetmore in reply assented saying: "But what chances did we take? We did not take such chances as this into consideration. We did not suppose under any circumstances, if the patent were finally sustained, that we could not buy lamps as well as anybody else; nor was any such policy suggested." Judge Lacombe here asked if it was a matter wholly unheard of in industrial history that the owners of patents had over and over again kept them entirely to themselves and been themselves the sole manufacturers.

Undoubtedly not, said Mr. Wetmore, but he was not aware that when a business, commenced as this had been, had grown up and been carried on as this had been, the owner of a patent after furnishing the public generally, for the public convenience, and all classes of the public his invention, could refuse to furnish the one excepted class.

At the close of the argument, Thursday afternoon, Dec. 8, Mr. Chaplin handed to the court the brief which he had been permitted to offer in behalf of the Mather Electric Company and of the United States Attorney for the District of Massachusetts.

THE EDISON LAMP DECISION SUSTAINED AND THE SAWYER-MAN CO. ENJOINED.

A DECISION was handed down on Dec. 15, by the United States Circuit Court of Appeals for this circuit, Judges Wallace, Lacombe, and Shipman sitting in the case of the Edison Electric Light Company against the Sawyer-Man Electric Company sustaining the decision of the Circuit Court granting a preliminary injunction against the Sawyer-Man people, restraining them from making any incandescent lamps in accordance with Edison's lamp patent No. 223,898.

Dyer & Seely Co. were the attorneys for the Edison Co., and Kerr & Curtis, for the Sawyer-Man Co.

The decision runs as follows:

UNITED STATES CIRCUIT COURT OF APPEALS.

For the Second Circuit.

EDISON ELECTRIC LIGHT COMPANY, AND EDISON GENERAL ELECTRIC COMPANY, Appellees, *vs.* SAWYER-MAN ELECTRIC COMPANY, Appellants.

Per Curiam.

This is an appeal from an order of the Circuit Court, granting an injunction *pendente lite* restraining the defendant from making, using, or vending the incandescent electric lamps of the patent granted to Thomas A. Edison, January 27, 1880, No. 223,898, of which the complainants are the owners. The order was granted *pro forma*, in the view that a final disposition of the questions involved might be promptly made by the decision of this Court.

The validity of the patent, and the infringement of its second claim by such lamps as the defendant makes, were adjudged by the Circuit Court for the Southern District of New York, July 14, 1891, in a decree at final hearing. That suit was brought against the United States Electric Lighting Company, and was defended by the Westinghouse Electric Company, a corporation which since October 10, 1888, has been the owner of the business carried on in the name of the present defendant. The business of the defendant consists exclusively in the manufacture of the infringing lamps. The decree of the Circuit Court adjudging the validity of the second claim of the patent, and its infringement by lamps such as are made by the defendant, was upon an appeal affirmed by this Court, October 4, 1892. That decree among other things awarded the complainants a perpetual injunction. The present suit was brought subsequently to that affirmance.

It is apparent that the order for the present injunction is in effect one to extend the terms of an injunction already granted in a suit determined by the Court of last resort between the same parties, or their privies, so as to include a new infringement. For an understanding of the grounds upon which the defendant contends the injunction ought not to have been granted, the following narrative is necessary:

For several years subsequent to 1880, the Edison Company and the United States Electric Lighting Company were the only manufacturers of incandescent lighting apparatus in this country doing any considerable business. The United States Electric Lighting Company began manufacturing incandescent lighting apparatus, including the lamps which have been held to be an infringement of the Edison patent, in the summer of 1880, and continued in such business until a recent period. In May, 1885, a suit was brought against it upon the present patent. Another corporation, the Consolidated Electric Lighting Company, was organized in September, 1882, and began the manufacture of incandescent lighting apparatus. This company was the owner of and operated under what are known as the Sawyer-Man patents for electric lighting apparatus; and under these patents it assumed that it had the exclusive right to make and sell the lamp claimed in the patent in suit. In May, 1885, suit was brought against it by the Edison Electric Light Company upon the patent in suit, and about the same time it brought suit against the Edison Company for infringement of its own patent. In 1883 a corporation known as the Thomson-Houston Company began the manufacture and sale of electric apparatus for lighting and power. As the result of negotiations between the Consolidated Electric Lighting Company and the Thomson-Houston Company, the Sawyer-Man Company, the present defendant, was organized in September, 1886. Nine-tenths of its stock was owned by the Thomson-Houston Company. It received from the Consolidated Company a license to manufacture lamps under the Sawyer-Man patents, and thereupon began the business of manufacturing the infringing lamp, and has continued in this business to the present time. In August, 1887, all the stock of the defendant, including that owned by the Thomson-Houston Company, was sold to the Consolidated Company for $120,000 in bonds, and the same amount at par of its stock. In December, 1888, the Thomson-Houston Company sold its stock in the Consolidated Company to the Westinghouse Electric Company. At the same time, by an agreement between the Consolidated Company and the Westinghouse Company, the fulfillment of which on the part of the Consolidated Company was guaranteed by the Westinghouse Company, the Thomson-Houston Company was licensed under the patents of the Consolidated Company to make incandescent lamps for export and use with generating apparatus of its own manufacture in this country; and the Westinghouse Company was prohibited from selling incandescent lamps for use with the Thomson-Houston generating apparatus for a period which might, at the option of the Thomson-Houston Company, extend to 1902. This agreement recognized the fact that the Thomson-Houston Company could during the continuance of the agreement make and sell lamps not covered by the Consolidated Company's patent; and in the event of such manufacture and sale, the latter company was released from its obligation not to sell lamps for use in connection with the Thomson-Houston generating apparatus. Pending the suit against the United States Electric Lighting Company, the Westinghouse Company succeeded to the business of the United States Company, the Consolidated Company, and the defendant; and since September, 1888, the defendant has been the manufacturer of lamps for the Westinghouse system. Each of the various companies engaged in the manufacture and sale of electric lighting apparatus has, as a rule, manufactured all the different pieces of apparatus which are necessary for making up a complete "plant," the different parts being constructed with reference to use with each other, and not so as to be adapted for use in the systems of apparatus made by other manufacturers. For the purpose of public lighting from central stations, local companies, known as illuminating companies, have been organized in various cities and towns, which have purchased plants from one or the other of the manufacturing companies, and the central stations of such illuminating companies have, as a rule, been equipped wholly with the electrical apparatus made by some one manufacturing company. In many cities and towns there are competing illuminating companies using the system of different manufacturers, some being equipped with the Edison system, some with the Westinghouse system, and some with the Thomson-Houston system.

The United States Company has installed about 1,050 plants, with a lamp capacity of about 350,000 lamps. About 300 of these plants were installed before the suit upon the patent, was brought against it. The Consolidated Company also installed a large number of plants. After the Westinghouse Company succeeded to the business of the United States Company and the Consolidated Company, it also installed a large number of plants.

It is said that the aggregate lamp capacity of the incandescent lighting plants installed with generating apparatus supplied by the Westinghouse Company at the present time represents a capital of about $25,000,000, and a lamp capacity of over 1,300,000 lamps. The lamps themselves represent but a small part of the cost of the plants, the greater part being represented by the electric apparatus supplied by the Westinghouse Company and its predecessors; but the lamps are essential for the continued operation of the plants. Unless the lamps can be replaced as they are worn out, and can be procured when needed, these plants will be crippled and the greater part of the investment in them will be lost. The central station plants supply lights to consumers as gas companies supply gas; and if their operation should be stopped great inconvenience to the public would ensue. The various companies give employment to a large number of men who might be thrown out of employment if the lamps could not be obtained.

In 1889 the Edison General Electric Company was organized for the purpose of combining the Edison Electric Light Company with various other corporations engaged in the manufacture and sale of electric apparatus, the organization of the subordinate corporations being retained. Prior to April, 1892, the Thomson-Houston Company had acquired the stocks of various other companies engaged in the business of manufacturing and selling electrical apparatus, and these companies were carrying on the business in combination with the Thomson-Houston Company and under its control. In April, 1892, these two combinations, the Edison General Electric Company, and the Thomson-Houston Electric Company, included substantially all the companies which had theretofore been competing in this kind of business, excepting the Westinghouse Company; and in that month the General Electric Company was organized for the purpose of combining these two combinations in one which should include all the concerns in this country, except the Westinghouse Company, which formerly were competing in the business of making and selling electric light and power apparatus; but the separate organization of the constituent companies was still retained.

The defendant insists that the preliminary injunction should not have been granted because: (1) Owing to the laches of the owners of the patent in asserting their claims and enforcing them, a large capital has been invested in the manufacture and sale, not only of the lamps, but also in electric lighting apparatus, which will be greatly depreciated in value unless the lamps can be used with it, and that an injunction will cripple and perhaps ruin the local illuminating companies who have invested in the plants of the Westinghouse Companies if they are prevented from using the lamp of the patent, and thereby subject to great inconvenience those whom these plants furnish with light, and displace a large number of persons who are employed in operating the plants; (2) Because the complainants and the other corporations with whom the complainants are associated, the competitors of the Westinghouse Company in business of making and supplying electric power and lighting, have entered into an unlawful combination to stifle competition in that business, and an injunction will be used unconscionably to further the objects of the combination; and (3) Because by reason of the affiliation of the Thomson-Houston Company with that combination and the prior dealings of that company with the defendant, the Consolidated Company, and the Westinghouse Company, an equitable estoppel has arisen by force of which the complainants, as parties to the combination, ought not to be permitted to have an injunction. The question whether there has been any laches in asserting the patent was considered by the Circuit Court of Appeals upon the appeal from the decree of the Circuit Court, and that court declared that no case was shown to authorize the refusal of an injunction on any theory of laches or equitable estoppel by reason of undue delay in bringing suit, or acquiescence in known infringement. If the owners of the patent proceeded with due diligence as respects the United States Lighting Company, no other infringers of the patent can be heard to complain with reason that suit was not brought against them upon the patent previous to the adjudication of its validity in the Circuit Court. It is a matter of notoriety that the litigation was a very expensive and arduous one; and its progress must have been familiar to all those who were extensively interested in having the patent defeated. As regards the present defendant, there are no new facts of importance bearing upon the question of laches to distinguish the case from that shown in the former suit. We see no reason for changing the opinion expressed by this court in the former case, and do not deem it necessary, because the same defence has again been urged upon substantially the same state of facts, to add anything to that opinion.

Every one of the manufacturing corporations, the competitors of the Edison Companies, commenced their operations with a knowledge of the existence of the patent in suit. They were controlled by business men of intelligence and experience. Their promoters and managers may have believed, and probably did, that the patent could not be successfully maintained. But they entered upon the business with an understanding of its risks, and of the consequences which would befall them as infringers, if the patent should be sustained. None of them can now be justly heard to say that an injunction which is essential, if not indispensable, to the protection of the owners of the patent and their licensees, ought not to be granted because of the great pecuniary loss which may result. If in consequence of being deprived of the use of the lamps, their investments in other electric apparatus will be greatly depreciated, they must take the consequences.

The users who have supplied themselves with electric lighting plants from the infringers, which required for their operation lamps of the patent, are of course infringers. But those who did so before the decision of the Circuit Court sustaining the patent and at a time when judicial decisions in foreign countries interpreting the patent were in conflict, and who are now willing to accept their lamps from the complainants upon reasonable terms, have much stronger equities than the manufacturing infringers. These equities the court will not disregard; but what would be reasonable terms, if an application were made to the court on behalf of these users, is a question which can only be determined in each case upon its particular circumstances.

As to those users, however, who have acquired these plants subsequent to the decision of the Circuit Court, if they are deprived of the use of the lamps, and as a consequence the value of their plants may be greatly impaired, they must accept the result as a consequence of their own imprudence.

We are not disposed to investigate upon the present case the character of the combination which has been formed under the name of the General Electric Company. Whether that combination is intended to fetter competition, and is illegal as one in restraint of trade, is a question which we should not undertake to decide upon the evidence before us and in a suit to which it is not a party. The present complainants are entitled by the patent laws to a monopoly for the term of the patent, of the manufacture and sale of the lamps made under it; the right to this monopoly is the very foundation of the patent system. They do not lose that right merely because they may have joined in a combination with others, holding other patents securing similar monopolies, which combination may, when judicially examined in a proper forum, be held to be unlawful. We do not feel justified in assuming upon the facts before us in the present suit that the use which the complainants propose to make of the injunction, an injunction which seems necessary to secure their monopoly and make their patent fruitful, will be such as to promote any other monopoly. When it shall be made to appear that some one, to whom in fairness and good conscience these complainants should sell their lamps, has been arbitrarily refused them, save upon oppressive and unreasonable terms, it will be time to consider whether the complainants should be allowed to continue in possession of the injunction.

The alleged estoppel seems to be far-fetched and shadowy. The history which has been given shows that before the Sawyer-Man Company was organized litigation upon the patent in suit and upon the Sawyer-Man patents had commenced; that in 1887, the stock in the Sawyer-Man Company owned by the Thomson-Houston Company was sold to the Consolidated Company, a party to the suits; and that subsequently, in 1888, the Westinghouse Company, an actual party to the litigation, bought that portion of the stock from the Consolidated Company which had been owned by the Thomson-Houston Company. The estoppel lacks the elements which ordinarily create an estoppel in pais, namely, an injury or a harm to one person resulting from a reliance upon the acts, conduct or declaration of another, in which there was an element of bad faith or wilful neglect of duty. The history of the connection of the Thomson-Houston Company from 1886 to 1888 with the Consolidated Company, and with the Sawyer-Man Company, the defendant, shows that all those companies knew of the existence of the litigations in which the life of the present patent, and of the Sawyer-Man patent was at stake. There can be no charge of concealment or constructive fraud. When the sale and the agreement of 1888 were made there was no implied obligation upon the Thomson-Houston Company to remain in alliance with the Westinghouse system. The contingency that it might enter upon the manufacture of competing lamps was contemplated. Its union with the Edison interests has neither hastened nor facilitated the application for the present injunction. We perceive no adequate reason from the facts why the complainants should not obtain the ordinary results which attend a complainant's success in a suit in equity for the infringement of a patent.

The injunction order appealed from should be modified so as to cover only lamps made in infringement of the second claim of the patent, the other claims not having been infringed according to the adjudication of the Circuit Court or of this Court. It should also contain a provision reserving the right to the defendant to move hereafter for the vacation, suspension or modification of the injunction upon proof of specific instances of refusal on the part of the complainants or either of them, to supply the lamps of the patent upon terms reasonable under the circumstances of the particular case, to the owners of electric lighting plants which were installed before the rendition of the interlocutory decree of the Circuit Court sustaining the validity of the patent.

HUNT vs. JOHNSTON—DECISION ON APPEAL IN FAVOR OF HUNT

THE Supreme Court, general term, has affirmed the judgment, with costs, in the case of the W. J. Johnston Company against Walter T. Hunt and the Electrical Age Publishing Company. The plaintiff sought to restrain Mr. Hunt from working for the Electrical Age Publishing Company, but Judge Truax at the Special Term, on the 12th of May last, dismissed the action in favor of the defendants. This judgment was appealed from with the result above stated.

LETTERS TO THE EDITOR.

ANTEDILUVIAN TELEPHONE TRANSMITTERS.

I SUPPOSE that the impending expiration of Bell's multiple telegraph (several opinionated old gentlemen to the contrary notwithstanding) patent next March, is beginning to exert a fructifying effect on the inventive genius of the country, and that the evidences thereof will increase and multiply from this time on. I would suggest, however, to inventors of entirely new forms of telephones that when they test the novelty of their productions by the prior state of the art, it might be advantageous to continue their researches through the records of some of the old litigations. An example of the utility of this course appears on comparing "the solid back, long-distance telephone transmitter" illustrated in your issue of November 16, 1892, with Daniel Drawbaugh's ancient "tumbler" or "teacup" instrument, and observing the interesting similarities which exist. While it is quite true that the usual method of calling abusive names is an excellent answer to any allegations of priority affecting any instrument in which the powers that be are, or are likely to become, interested, it may be pointed out that the evidence of the existence of the said tumbler or teacup instrument a dozen years ago will be found in the records of the complainants in these old cases; and the fact that such instruments were used, not merely in a horizontal, but also in a vertical, position, was made the subject of specially virtuous indignation on the part of the Bell counsel in their comments on certain of the Drawbaugh tests. Meanwhile, I should imagine that the promoters of this last form of telephone would derive much pleasure from reading all the reasons which were adduced on the part of the Bell interest to prove that such an instrument, even if it existed at the still earlier date then in controversy, could never have worked satisfactorily.

But even this, like all pleasure, is merely relative. For do we not know, that nothing which can possibly happen during the next eighteen months will rival as a source of abstract joy and intellectual delight, the gyrations which a refurbished Bell Telephone Literary Bureau is going to make in order to reconcile anybody and everything in the interests of truth, justice and the Bell stockholders.

PARK BENJAMIN.

NEW YORK.

COMPOUND WOUND MACHINES.

APROPOS of Mr. Willis' recent paper before the Chicago Electric Club on "Compound Wound Generators," let us have a little light on the subject of the "variable shunt" on the series field.

The Thomson-Houston machine has a German silver fluted strip very familiar to most of us. In years past in many instances to the writer's knowledge, these shunts were removed from incandescent machines without any appreciable bad result. Quite recently two 100 K. W. Edison railway generators were carefully tested for effect of varying this shunt to the series coil. No change of voltage could be discerned with or without load, and with the machines both hot and cold. Engineers of experience who have been questioned report similar results of non effect of variation.

J. STANFORD BROWN.

THE SAFETY OF ELECTRIC ELEVATORS.

REFERRING to the comments by Mr. Rosenbaum in your issue of December 14, I have no doubt that my knowledge of the action and use of motors on elevator, as well as on other service, is limited, and I confess I am rather glad of it, for it leaves me the hope of learning something more; but I must be pardoned if I express myself as reasonably content with the limitations, such as they are, and decline to unnecessarily discuss the utility of the commonest and most easily handled electrical devices for protection of machines and circuits which may be called into play when the safety factor of the hoisting ropes is wilfully exceeded.

NEW YORK, December 16, 1892.

FRANK J. SPRAGUE.

THE DRIFTLESS BALLISTIC GALVANOMETER.

IN an interesting article in your valuable journal of Nov. 16, Mr. Elmer G. Willyoung gives an account of a ballistic galvanometer used by Messrs. Queen & Company. As a scientific man should do, Mr. Willyoung gives due credit to Mr. Northrup for an improvement in the needle for more easily adjusting the degree of astaticism. Though in this case he gives due credit for design, we fail to see why he omits to mention that the whole general plan is a barefaced copy of our ballistic galvanometer described in THE ELECTRICAL ENGINEER of April 15, 1891, and fully illustrated. All the confirmation required of this statement would be to print the two engravings side by side.

We should not have expected such treatment at Mr. Willyoung's hands, though we presumed the conscience of Messrs. Queen & Company, as traders, would be of a different order.

NALDER BROS. & CO.

LONDON, Dec. 1892.

SOCIETY AND CLUB NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

THE 72d meeting will be held at the Headquarters of the Institute, 12 West Thirty-first street, Wednesday, December 21, at 8 p. m. The change from the usual meeting night of Tuesday has been made in order to permit suitable preparations. The paper for the meeting is entitled: "Seven Years' Experience in Armature Insulation," by Mr. E. P. Thompson, member, for Messrs. C. W. Jefferson aud A. H. S. Dyer. Advance copies of the paper will be sent on application, and will be distributed at the meeting. There will be exhibits illustrating the steps in the manufacture of armatures and the results obtained. The author suggests the following topics for discussion in connection with the paper:

SUGGESTIVE TOPICS.

Armature.—Rigidity and its dependence upon insulating material employed. What has been learned by observation and special tests?

Preservation of Insulation.—Is it better to try to remove the cause of heating, or to neutralize the heat?

Burning Out Armatures.—What does insulation have to do with it, and what are the remedies? Also, what are the causes?

Durability of Insulation.—Differences in connection with armatures for inside use, such as installations and outside, *i. e.*, railway, mining and elevator use. Effects of atmosphere, motion and rough treatment.

Financial.—Does the expense of insulation, if the best, have an appreciable effect upon the cost of construction, and, on the other hand, will it pay in the end to put in a cheaper material?

Comparative Merits of Insulating Materials for Different Conditions.—Effects of high potential. Power to resist spark-puncturing. What have tests shown as to properties of materials to withstand "breakdowns," independently of high ohmic resistance?

The discussion will be opened by Messrs. W. J. Hammer, Chas. Steinmetz and Harold Binney. Dr. J. B. Williams will also make comparative tests of different samples of insulating material considered suitable for this class of work, and manufacturers and dealers are invited to send specimens to the secretary, which should be about two inches square and $\frac{1}{16}$ inch thick or less. Gentlemen who are not identified with the Institute, are cordially invited to attend.

BUFFALO ELECTRICAL SOCIETY.

AT a meeting of the Buffalo Electrical Society held December 5th, Mr. P. K. Stern read an interesting paper on Electric Heaters. The attendance at this meeting shows that the Society has opened the season with its old time enthusiasm. At the next meeting Mr. Frank Kitton will deliver a lecture on Magnetism, and at a subsequent meeting, Mr. A. C. Terry will lecture on the subject of Electric Motors, treating it in a popular and elementary way. The Society is considering the project of a series of lectures on Electrical Engineering known as the University Extension Course. The members of the Buffalo Society of Natural Sciences are very much interested in this course of lectures and the prospects are that the plan will be eminently successful. The lectures will be delivered by one of the best electrical engineers in the State.

The following officers have been elected for the years 1892–1893: President, Frank Kitton; vice-president, P. K. Stern; secretary, Astley C. Terry; treasurer, Samuel Stewart; librarian, John G. McNerney; executive committee, Frank Kitton, A. C. Terry, F. P. Jones, John P. Chapin, P. K. Stern, Samuel Stewart, F. A. Hallock, Geo. A. Burnett.

THE MANCHESTER, N. H., ELECTRIC CLUB.

THE Manchester Electric Club is meeting with astonishing success, and at its regular meeting, Nov. 15, seven new members were elected. Commodious club rooms have been secured in Opera block to which members have access at all times. The leading electrical journals will be subscribed for, such as THE ELECTRICAL ENGINEER, *World*, *Review*, *Power*, *Scientific American*, *Power-Steam*, etc. The club gave the best stereopticon returns in the city on election night, which netted a snug sum for the treasury. The club has passed a resolution heartily endorsing the efforts of the Board of Trade to secure a first-class electric street railway system in the city. Mr. Herbert W. Eastman is secretary.

FRANKLIN ELECTRICAL SOCIETY.

AN informal reception will be held by the Franklin Electrical Society at Vienna Hall, Lexington avenue, near 58th street, on the evening of December 24.

PERSONAL.

MR. WM. H. PREECE, F. R. S.

The vacancy caused by the recent death of Mr. Edward Graves, chief engineer of the British Postal Telegraphs, has been filled by the appointment to that post of Mr. Wm. H. Preece, F. R. S. Mr. Preece has for many years been the chief electrician of the British Postal Telegraphs, and his appointment as engineer-in-chief and electrician is a well merited reward for intelligent service and honest work through many years. We extend to Mr. Preece our sincere congratulations.

Mr. J. H. Watermann, of the engineering force of the Westinghouse Company, who has charge of the installation of the new Woodland avenue line in Cleveland, Ohio, informs us that the road will be in operation in a very short time. Mr. Waterman's originality and skill as an engineer is shown in numerous ways throughout the installation and from present indications there is no doubt but that he will leave behind him a plant which, from station to rolling stock, will be a model in railway engineering.

OBITUARY.

MARMADUKE M. M. SLATTERY.

News comes from Fort Wayne, Ind., of the death there, suddenly, on Dec. 14, from hemorrhage of the lungs, of M. M. M. Slattery, the inventor and patentee of the Slattery alternating system and apparatus manufactured by the Fort Wayne Electric Company. Mr. Slattery, who was a native of Great Britain, was for many years actively engaged in the field of electric light and power. He became prominent about eight or nine years ago, when his name was coupled with many ingenious devices for cutting incandescent lamps into and out of arc circuits, and for giving greater flexibility and range to the incandescent system. Some of these devices were exploited by the Swift Electric Company. About that time the alternating method came to the front, and Mr. Slattery threw himself energetically upon work in that department, and the Fort Wayne Jenney Company put on the market a system bearing his name, complete in all the details required for that class of generation and supply. Mr. Slattery enjoyed the active support of Mr. R. T. McDonald, and the Fort Wayne Company soon became a dominant factor in the business, remaining so down to the present time, which finds it one of the allies or affiliated members of what is popularly known as the General Electric "Trust," its separate organization and activity being maintained.

Of late years, Mr. Slattery has been less prolific of inventions, but has busied himself with many ideas, one of which has been the use of storage batteries with street cars and tricycles. He was never very strong and has been in poor health for months past. He was a man of many acquaintances and of warm friendships, delighting not a little in social pleasures, and adding his share with a ready wit and a wonderful knack of mimicry. They who ever heard his definition of Electricity, delivered as an after dinner speech, are not likely to forget it.

PATENT NOTES.

TESLA'S SYSTEM OF MULTIPHASE DISTRIBUTION.

As is frequently the case, inventions are exploited and worked commercially before the issuance of the patents thereon, and not infrequently much injustice is done to the inventor by reason of the fact that the public is in ignorance of the date of the filing of the application. A striking instance of this character is the patent issued to Mr. Tesla on Dec. 13, 1892, No. 487,796, entitled "System of Electrical Transmission of Power."

While most of the features embodied in this patent are now well known in the art, the fact that the application was filed as far back as May 15, 1888, shows that even at that remarkably early date Mr. Tesla's ideas on the subject were clearly defined. The underlying principle embodied in this patent is to adapt the Tesla system to the type of alternating machinery now in general use. Thus there are described various methods of obtaining the required phase difference with ordinary multipolar alternators, by winding or coupling machines in various ways, together with other features whereby a single generator may run a number of motors either at the same speed as its own or all at different speeds.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED DECEMBER 6, 1892.

Alarms and Signals :—

Electric Bell, P. Wagner, New York, 487,437. Filed Oct, 3, 1891.

Has for its object to increase the striking force of electric bells and do away with the retaining spring.

Steam Boiler Indicator, G. L. McDermott, Neenah, Wis., 487,634. Filed July 26, 1892.

Electric Signaling Apparatus, M. Martin, Malden, Mass., 487,676. Filed Feb. 20, 1892.

Comprises a paper feeding train of wheelwork, and an electromagnet and armature controlled by the transmitting circuit combined with a circuit controller, one member of which is operated by the wheelwork and the other by the electromagnet.

Distribution :—

Apparatus for Distribution of Electricity, T. Tomlinson, London, 487,356. Filed May 25, 1891.

An automatic transformer system avoiding the necessity of employing an attendant at the sub station.

System of Electrical Distribution, O. B. Shallenberger, Rochester, 487,548. Filed Oct. 12, 1886.

Invention consists in employing several leads running to different converters and placing in each lead a regulating device.

Dynamos and Motors :—

Electric Motor, F. H. Beers, Newark, N. J., 487,242. Filed Feb. 26, 1892.

Claim :

A revolving armature, one field magnet pole arranged exteriorly to such armature and one field magnet pole mounted interiorly to such armature, the said field magnet poles being arranged on opposite sides of the axis of motion.

Connection for Commutators and Armature Wires, E. P. Warner, Chicago, Ill., 487,307. Filed March 5, 1892.

Provides ready means for attaching or detaching the wires to or from the commutator segments by means of a binding screw.

Connection Plate for Dynamos, J. J. Wood, Fort Wayne, Ind., 487,462. Filed April 18, 1892.

The line circuit and the exciting coils have their terminals fastened to terminal connectors constructed as fuse blocks and so arranged as to afford convenient access.

Galvanic and Thermo-Electric Batteries:—

Galvanic Battery, J. L. Gethins, Boston, 487,824. Filed May 15, 1891.

Employs a copper electrode consisting of a cylindrical portion surrounding the sides of the porous cup and a plurality of radiating wings underneath the cup.

Heating:—

Electrical Heater, W. Mitchell, Malden, Mass., 487,285. Filed March 15, 1892.

A stove partly composed of magnetic material provided with studs having wire wound upon them.

Lamps and Appurtenances :—

Electric Arc Lamp, J. J. Wood, Fort Wayne, Ind., 487,315. Filed July 25, 1892.

Employs a feed clutch consisting of a sleeve embracing the feed rod, and a clutch lever pivoted to the sleeve having a brake shoe engaging the rod beneath its pivot.

Incandescent Electric Lamp, E. W. Applegate, Omaha, Neb., 487,360. Filed Feb. 29, 1892.

Provides means for repairing the filament without sacrificing the globe.

Incandescent Electric Lamp, G. A. Frei, Springfield, Mass., 487,477. Filed May 14, 1892.

Provides means for renewing the filaments of electric lamps and for securing a new filament to the leading in wire.

Mercurial Air Pump, G. A. Frei, Springfield, Mass., 487,478. Filed April 11, 1892.

Incandescent Electric Lamp, G. A. Frei, Springfield, Mass., 487,479. Filed April 11, 1892.

Has for its object to renew the lamp in case of the destruction of the filament by the substitution of certain parts only, and by persons not especially skilled in the art.

Metal Working :—

Method of Electric Welding, E. Thomson, Swampscott, Mass., 487,302. Filed Oct. 2, 1890.

Invention consists in making contact with both pieces to be united and passing a current of greater strength through one piece and then through the other.

Method of Arc and Incandescent Metal Heating, C. L. Coffin, Detroit, Mich. 487,607. Filed Aug. 6, 1892.

Consists of heating the material on one side by contact with the conductor in electrical connection with one terminal of the generator and on the other side by an electric arc.

Miscellaneous:—

Resistance Box, J. Waring, Manchester, Conn., 487,306, Filed April 28, 1892.

Comprises a bottom having a chamber for the resistance coils and a chamber for the contact plugs separated by insulation and having perforations in the top to coincide with the plug socket between the blocks.

Compass, P. J. Kaiser, Leyden Noordeinde, Netherlands, 487,330. Filed Feb. 11, 1891.

Jail, D. E. Osbourne, St. Paul, Minn., 487,448. Filed Aug. 6, 1892.

Electrical Device for Preventing Cribbing in Horses, G. W. Whitefield, Evanston, Ill., 487,461. Filed Sept. 4, 1891.

Thermostat, F. O. Elliott, Catawba, N. C., 487,519. Filed Aug. 20, 1892.

Process of and Apparatus for Generating Electricity, J. S. Rodgers, New York, 487,644. Filed April 14, 1892.

Consists in exposing a fusible electrolyte capable of being deoxidized and re-oxidized while in a state of fusion in the presence of suitable electrodes to a current of a deoxidizing gas injected in one direction, and a current of reoxidizing gas injected in the opposite direction.

Electro-Therapeutic Process and Apparatus, J. M. Wardel, Cadillac, Mich., 487,655. Filed Feb. 20, 1892.

An electric syringe.

Railways and Appliances :—

Electric Motor for Cars, C. A. Jackson, Reading, Mass., 487,329. Filed Aug. 3, 1891.

Provides means for changing the direction of rotation without stopping the motion.

Clamp for Electric Conductors, H. Lindahl, Chicago, Ill., 487,382. Filed Feb. 5, 1892.

A trolley clamp having a series of tongues on one plate and sockets on the other for additional security.

Closed Conduits for Electric Railways, A. A. Vanderpool, Newark, N. J., 487,654. Filed Mar. 18, 1890.

Employs an elastic closer for the slot of an electric conduit.

Telephones and Apparatus :—

Telephone Holder, E. C. Lewis, Woonsocket, R. I., 487,369. Filed Apr. 29, 1892.

AN IDEAL CENTRAL POWER STATION.

As we go to press we are in receipt of a copy of a paper by Messrs. C. J. Field and F. Bourne, read at the meeting of the Chicago Electric Club, on December 19. In their most excellent presentation of this important subject the authors assume a station having a capacity of 6,000 h. p. and consider first, the question of the unit of power to be adopted. This must, of course, depend largely on the ultimate capacity of the station, and in the case assumed a unit of 1,000 h. p. is adopted as the most economical. The authors then discuss the question of direct connection vs. belting and arrive at the conclusion that the former is to be preferred, one important consideration being the fact that a belted plant occupies twice the space of a direct-connected. The authors point out, however, that ample fly-wheel capacity is necessary in order to withstand the shocks caused by short circuits and sudden over-loading

The specifications for buildings and engines are then taken up. On the latter point the authors believe that the best results can be obtained by the adoption of a type of engine occupying a middle ground between the modern high speed and the Corliss engine, and combining the best features of both. The boilers and piping are also fully considered.

The generators, switchboards, and other electrical auxiliaries are then described, the authors giving the results of the best practice of to-day in operating large stations.

The paper contains much valuable information and we hope to print a fuller abstract in our next issue.

RULES RELATING TO ELECTRIC LIGHTING AND POWER SERVICE AT THE WORLD'S FAIR.—I.

The rules relating to electric lighting and power service at the World's Fair, as adopted by the national commission, are given below. These rules have not all been approved by the local committees, however, and are liable to change.

ELECTRICITY FOR INCANDESCENT LIGHTING SERVICE.

All state and territorial World's Fair boards, persons, firms or corporations who may desire to wire their respective buildings for the purpose of lighting same shall so install said wiring as to meet with the approval of the director of works before connections can be made with the main circuit.

All power service for generating light will be furnished during the exposition hours by the World's Columbian Exposition from the 1st of May to the 30th of October, 1893, at the rate of $8.00 per 16 candle power lamp capacity or the equivalent in lamps of other candle power. All changes in the location of lamps or appliances when once installed will be made subject to an extra charge, to be fixed and determined by the director-general and the director of works. The incandescent lighting circuit will be operated from 100 to 110 volt alternating circuits.

ELECTRICITY FOR POWER SERVICE.

First—All contracts to be made with exhibitors for power service shall be executed between said exhibitors, the director-general and the director of works, but the amount of power to be supplied to the exhibitor in each case shall be fixed and determined upon by the director-general.

Second—The electric motor shall be suitable to operate on a 500 volt constant potential circuit.

Third—The rheostat shall be constructed wholly of non-combustible material.

Fourth—The main line switch shall be of the knife blade type and suitable for working a 500 volt constant potential circuit.

Fifth—The motor shall be erected in position by and at the expense of the consumer and in a manner subject to the approval of the director-general and the director of works.

Sixth—The service connections to the motors shall be installed, maintained and owned by the World's Columbian Exposition.

Seventh—No service will be rendered for less than $20.00. Fractions of horse power will not be considered except for motors of less than 1 horse power.

Eighth—Charges will be made for service of connecting the main line at the following rates :

For ½ horse power and less.	$10.00	per horse power.
For 1 to 5 horse power..................	15.00	" "
For more than 5 horse power and not exceeding 10 horse-power............	12.00	" "
For more than 10 horse power............	10.00	" "

Ninth—Charges for service will be based upon the maximum mechanical horse power delivered to the motor, irrespective of the class of work to be operated by motor, at the following rates :

For ¼ horse power and less......	$20.00	per horse power.
For more than ¼ horse power and not exceeding ½ horse power	40.00	" "
For more than ½ horse power and not exceeding 1 horse power...............	75.00	" "
For more than 1 horse power and not exceeding 2 horse power...............	70.00	" "
For more than 2 horse power and not exceeding 3 horse power...............	60.00	" "
For more than 3 horse power............	60.00	" "

Tenth—Special service for motors not exceeding 2 horse power can be furnished on quarter phase alternating current circuit.

ELECTRICITY FOR ARC LIGHTING.

The aisles of the main building will be illuminated by arc lights free of expense to the exhibitor. A limited number of arc lights will be supplied for private lighting on the following basis, viz.:

First—The consumer shall pay the cost of wiring.

Second—The consumer shall pay for service from May 1 to October 30, 1893, at the rate of $60 per lamp of 2,000 nominal candle power.

Third—Lamps will be suspended from the ceiling and furnished with opalescent globes. If any special fixture is required, it shall be furnished by the consumer.

Fourth—All care and attendance to the lamps and circuits will be furnished by the World's Columbian Exposition without extra charge.

ELECTRICITY FOR CHARGING STORAGE BATTERIES.

First—The consumer shall provide lines and all material necessary from the local switchboard from which the current is to be distributed to storage batteries.

Second—The consumer shall provide all necessary labor and attendance connected with the charging or handling of the batteries.

Third—Current will be provided at 110 to 220 or 500 volts, at the rate of 10 cents per electrical horse power per hour.

ELECTRICITY FOR MISCELLANEOUS PURPOSES.

First—Electricity for special purposes will be subject to special agreement, to be determined at the time of making application therefor.

Second—Rates will be based either on those of power or those for storage battery purposes, according to the class of work to be performed.

QUEEN & CO.'S TESTING SETS.

Messrs. Queen & Co., Philadelphia, are meeting with great success in exploiting their standard portable testing sets.

One purchaser says :

> The portable testing set referred to has been in use constantly since we received it, and we find it to be first-class in every respect. Have used it on all kinds of work, for both high and low measurements, and think it is about as complete an instrument of the kind, as I have ever used.

Another writes :

> In answer to your inquiry under date of Nov. 21, would say that testing set No. T 805, marked 487, has given us most satisfactory results and we feel thoroughly satisfied with it in detail. It has won our confidence to the extent that we accept it as a standard, not only as a portable instrument, but in a greater share of our laboratory work and electrical measurements. It is correct to within a small degree, easily manipulated, and results quickly obtainable, and can say that we do not know of one single point left to be desired in this instrument for an instrument of this nature.

These instruments are made in a first-class manner, and are adapted for use under the most exacting conditions, such as in a manhole or close to dynamo machinery.

F. P. LITTLE & CO.

Messrs. F. P. Little & Co., of Buffalo, N. Y., have recently closed contracts as follows: a 10-light arc dynamo, and a 50-light incandescent dynamo, for the Atlas Oil Refining Company; a D-10 Thomson-Houston dynamo, set up complete, and 18–2,000 c. p. arc lights, for the East Buffalo Iron Works; and a D-7½ Thomson-Houston dynamo and Rice automatic engine for the planing mill of Messrs. Meyer & Metz. All the wiring and fitting is included in the last piece of work.

A LAMP AGENCY WANTED.

The firm of De Lew & Bailey, electrical and mechanical engineers, of 213 East Lombard street, Baltimore, Md., wish to secure the agency for an incandescent lamp of high efficiency and long life. The sole agency only will be considered.

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

He who advertises is always in circuit.

THE RUSSELL AUTOMATIC SWITCH.

BY

Edward R. Grier

YOU may have a light in your hall and want to turn it on or off from your bed-room, from your vestibule, from your second-floor hall and even from more places; you may want to control all the lights from one place; you may wish to light your stable and hold the key to the situation under your own thumb; in fact there are a number of things you may wish to do and perhaps when you have read this article on the Russell Switch you will find it is the key to the unopened door of your desires.

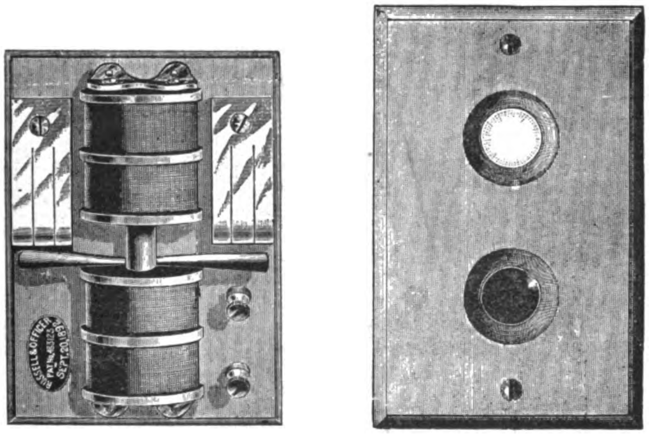
The illustration, Fig. 1, shows the switch—two spools of wire, a movable soft-iron core held by brass guides, a bar of copper extending at right angles, two sets of brushes, all mounted on a substantial porcelain or wood base.

The illustration, Fig. 2, is the push-button—two buttons, one black and one white, three points to connect your wires, same as the ordinary push-button used for automatic gas-burners. You may use as many of these push-buttons as you like and put them anywhere: all you need is No. 18 wire, the switch and the buttons—*no battery.*

You push the white button on any one of the pushes and instantly the little iron core is drawn into the centre of the spool to the right, engaging the copper bar in the meshes of the copper brushes, closing the circuit; touch the black button of any push and as quickly the circuit is opened.

The engraving, Fig. 3, shows the way to wire it. You notice two wires running parallel; these are the main wires. The switch is wired on the branch wires of the circuit which it is to control.

The wire A which is one side of the circuit connects to one binding-post of the brushes marked B, and a wire connected to the other binding-post D, continuing that side of the circuit, the switch being connected just as an ordinary single pole switch. The other side of the branch wire runs directly to the lamps—which in the diagram are shown as circles with little rays marked around them to assist in the conception. This is all there is to putting the switch in circuit and the buttons in circuit; the wiring is very simple.



FIGS. 1 AND 2.—THE RUSSELL AUTOMATIC SWITCH.

A button has three connections. A main connection under each push. Wire O, which is marked shunt, connects to the side of the branch wire which is not connected to the switch and runs to the main connection of the push. This wire can be extended to as many pushes as desired and its length does not interfere, as the resistance of this circuit is of no consequence.

From the connections under each of the black and white buttons a wire is extended to the switch, one connecting at E and one at G. The two binding-posts E and G are connected each to one of the spools of wire and the ends of the spools are connected to the binding-posts of the brushes.

When either button is pressed, closing the circuit, it makes a connection between the positive and negative side of the circuit and excites either one of the spools. This circuit is of high resistance but the great number of turns of wire on the spools give a strong magnetic pull, a pull equal to from seven to fifteen pounds according to the capacity of the switch, and the action is instantaneous. The amount of current required is small and the wires connecting the switch are only alive as long as the button is pressed.

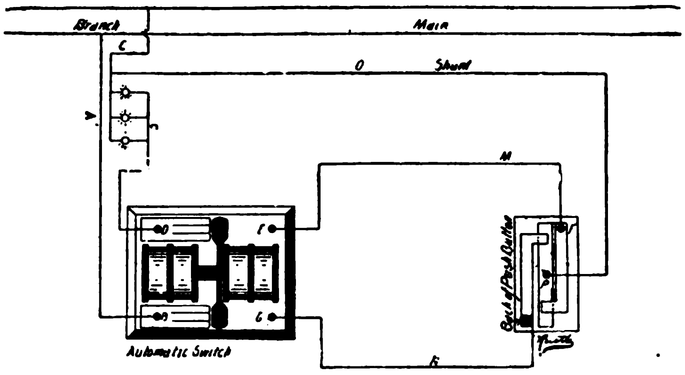


FIG. 3.—THE RUSSELL AUTOMATIC SWITCH.

Lights located in out-of-the-way places may be controlled by this switch and a great saving in wire can be made as the switch can be placed at the cut-out box and the branch circuit run direct to the lights, while only No. 18 wire need be run to the push-button. Not only can the amount of heavy wire be saved that would be required to run to an ordinary switch, but the size of the wire necessary for this circuit will be smaller because the length of the circuit will be reduced by the distance which would have been taken up by the switch loop.

DAILY SALES OF WESTINGHOUSE ENGINES.

MESSRS. WESTINGHOUSE, CHURCH, KERR & COMPANY have issued a list of their daily sales of engines during the month of October, showing a total of 98 engines having an aggregate of 7,525 h. p. One of these orders makes the 68th given by the same company. The engines are consigned to all parts of the earth, from Monterey to Moscow and intermediate points.

STEWARD'S LAVA INSULATION.

THE growth in popularity of the Lava insulation of the D. M. Steward Manufacturing Company of Chattanooga, Tenn., is very rapid, but not remarkable, in view of the excellence of the material. The company's orders are more numerous and larger than ever before in its history; and in fact the factory is pushed beyond its capacity in many directions.

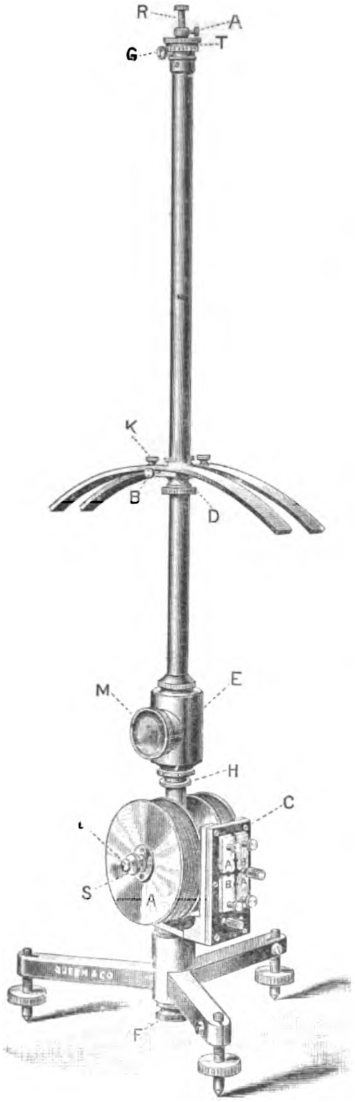
WARREN WEBSTER & CO.

THE good points of the "vacuum" feed water heater and purifier, manufactured by Messrs. Warren Webster & Co., of 491 N. Third street, Philadelphia, are fully set forth in the attractive 112-page catalogue recently issued by them. The pamphlet contains a detailed description of the heaters and purifiers, a partial list of those now using them, covering nine pages, and a large number of fac-simile letters that speak in the highest terms of the apparatus. A list of 33 new orders from all over the country received during the month of November constitutes a supplement to the catalogue.

SCHOOP'S GELATINE ELECTROLYTE FOR STORAGE-BATTERIES.

WE are informed that the Accumulatoren-Fabrik-Aktiengesellschaft, of Germany, has acquired the rights of Dr. Schoop's patent on gelatine electrolyte for storage batteries, for the entire continent of Europe. The tests of this material which have extended for a number of years, have demonstrated its excellent properties for storage-battery work, both in stationary and in portable installations.

QUEEN'S DEAD-BEAT REFLECTING GALVANOMETER.



Queen Dead-Beat Galvanometer.

The instrument illustrated herewith is a modification of the Weidemann galvanometer, and is adapted for both differential and direct work. The coils (A) are graded, having five changes of wire, and slip upon copper rods forming part of the damper.

Automatic connections are made with the binding posts on the switchboard (C) by means of small spring contacts upon the back of the board which press against platinized studs attached to the coils. By shifting plugs on the switchboard, the coils may be quickly connected in series, multiple, or differentially. To obtain perfect differential adjustment, a horizontal movement of the coils is secured by turning the micrometer screw (S).

The vertical tube is 24 inches long. The suspension being quartz fibre instead of cocoon silk, torsion is practically eliminated while great tensile strength is secured.

An essential feature of the apparatus is the arrangement of control magnet employed. In place of the usual single piece with the suspension tube passing through it, the magnet is divided into two parts, each of half the usual cross section, as illustrated.

The advantage of the construction is that should it be necessary to make very delicate observations in the vicinity of the instrument, the magnet may be temporarily removed without disturbing any adjustments, and then replaced in exactly the same position. Owing to the mass of copper in which the magnetic system moves, the galvanometer is almost absolutely dead-beat, and observations may be taken in rapid succession. This apparatus is of recent design, and placed on the market by Queen & Company, Philadelphia, from whom further particulars can be obtained.

"SALAMANDER" WIRE.

We have received from the Washburn & Moen Mfg. Co., a sample board illustrative of tests made with three leading makes of insulated wire, and one Salamander wire that had been subjected to the passage of 150 amperes for two minutes. The "Salamander" remains in fine condition; some of the others are very much like Mr. Krook, in Dickens's story, who disappeared and left only a dark grease spot behind. It is noticeable that the "Salamader" is also twisted in a knot and pulled tight. So far as the water-proof qualities go, it may be mentioned that the Massachusetts Electrical Engineering Co., of Boston, has made tests which show a resistance of 5,000 megohms and over, after submersion of the wire in salt water from six to ten days.

THE HUYETT & SMITH MANUFACTURING COMPANY.

As an earnest of the rapid increase in the number of their friends and customers the Huyett & Smith Mfg. Company, of Detroit, have issued a new 100-page catalogue descriptive of their apparatus as manufactured with their increased facilities which rapidly increasing orders made necessary. The company assert that there is no known problem for moving air that can not be economically solved by means of their apparatus. They are manufacturers of dry kilns, brick dryers, hot blast and ventilating apparatus, blowers, engines, boilers, dust separators, cotton fans, exhaust fans, steam traps, etc., and are constantly adding new apparatus to the list.

HEATING BY ELECTRICITY IN OTTAWA.

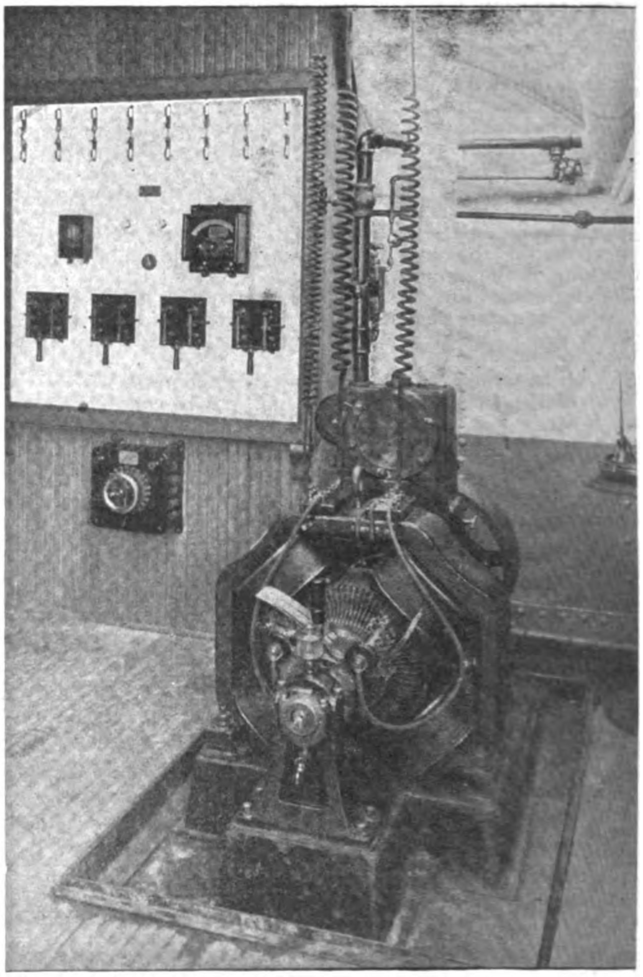
Mr. R. A. McCormack, a druggist at Ottawa, Can., is warming his store with Ahearn electric hot-water heaters. The water for the coils is contained in five heaters in the cellar, the total capacity being about 23 gallons. About 300 feet of pipe are used in the store, and the piping is divided into sections. The apparatus takes up about one quarter the space occupied by a furnace and boiler.

WOODBURY ENGINES.

The Stearns Manufacturing Company, Erie, Pa., builders of the Woodbury engines, report the shipment of a large number of engines recently—38 of the simple type, and three large tandem compounds. Of these, five engines were for manufacturing purposes, two for electric power uses, and the remainder for electric light plants.

LIGHTING THE WHALEBACK "PILLSBURY."

We illustrate on this page a very compact, combination, one-base plant for ship lighting. It is the first electrical plant ever placed upon a steamship of the whaleback type, and was installed on the "Pillsbury," when building at West Superior, Wis. Considerations of space entered largely into the question of this installation, and a small room, eight feet square, was all that could be spared. This precluded the employment of a belt connected plant, and a generating set of the General Electric Company type was therefore adopted.



The Lighting Plant of the Whaleback, "Pillsbury."

The dynamo, of the four pole type, is of 150 lights capacity, and is directly coupled to a fifteen horse power engine, both having a common bed-plate. Behind the engine and attached to the wall is the white marble incombustible switchboard. The dynamo room is located in the after portion of the vessel on the first lower deck. The vessel is wired in the usual manner for one hundred and fifty lights, the best grade of wire for marine purposes being employed. This installation, and that on the sister whaleback, the "Washburn," were effected by the Isolated Lighting Department of the Northwest General Electric Company.

NEW YORK NOTES.

Caldwell Water Tube Boiler.—The following are among recent orders for Caldwell water tube boilers, office 15 Cortlandt street, New York City: H. J. Hoerner & Company, Newark, N. J., 60 h. p.; Johnson R. R. Signal Company, Rahway, N. J., 120 h. p.; Polson Iron Works Company, Toronto, Ont., 984 h. p.; Norfolk, Albemarle & Atlantic R. R. Company (Princess Anne Hotel, Virginia Beach, Va.), 110 h. p.; Tiffany & Co., Jewelers, New York City (new factory Newark, N. J.), 103 h. p. The concern have secured, as selling agent, the services of Mr. P. M. McLaren, who for many years held a prominent position on the staff of the Babcock and Wilcox Company. The inventor, Mr. John A. Caldwell, has recently added important improvements, largely affecting the steaming capacity of this type of boiler, which is said to be attracting considerable attention from engineers. The company is also in the market with an entirely new departure in "Dry pipes" applicable to every boiler in use, and which is intended to prevent "flooding" of the engines under any circumstances. The Caldwell boiler and appliances are manufactured by the well-known firm of D. H. Burrell & Company, of Little Falls, N. Y., at their Poughkeepsie shops.

The Interior Conduit and Insulation Company, of New York, in order to meet the large and increasing demand for their product throughout the New England States, have found it necessary to provide a stock of their Interior Conduit and fittings, Lundell fan and power motors, etc., etc., to be carried in the city of Boston, and have appointed the well known firm of Pettingell-Andrews Co., of that city, as their sole agents for the States of New Hampshire, Vermont, Massachusetts, Connecticut and Rhode Island. This firm have enlarged and made alterations in their storerooms with the view of carrying a large and complete stock of the company's goods. The Interior Conduit Company have shipped them their first stock order consisting of some 200,000 feet of both plain and brass covered conduit tubing and junction boxes, couplings, elbows and other appliances in proportionate amounts. This, the latest move on the part of the Interior Conduit and Insulation Company, will doubtless be appreciated by the entire New England trade.

Mr. Edward E. Higgins, formerly the general manager of the Short Electric Railway Company, has opened an office at 35 Wall street, Mills Building, New York, as street railway consulting engineer and financial counsel. Mr. Higgins has been identified with street railway interests for several years, and his thorough knowledge of the business makes him an excellent adviser to intending purchasers.

PHILADELPHIA NOTES.

M. R. Muckle, Jr., & Co.—It is always a satisfaction to have customers return with their further orders, and Messrs. M. R. Muckle, Jr., & Co., are congratulating themselves on having sold a third plant to Mr. C. S. Garrett, the paper manufacturer. They sold him his first plant of a shunt-wound dynamo for his Keystone mill in West Philadelphia some five years ago, which was followed later by a compound-wound machine for his Marley mills in Maryland. They have now received an order for another compound-wound machine to be placed in the Beaver Dam mill at Beaver Dam, Pa. These are particularly interesting installations, as Mr. Garrett makes at his mills large quantities of the paper used for making the various kinds of hard fibre goods used so much for electrical work.

The Philadelphia Bank following the march of improvement has completely remodelled its handsome building on Chestnut street, and is putting up in connection therewith, a large office building. For the lighting of this new plant, Messrs. M. R. Muckle, Jr., & Co. are installing two 600-light dynamos and one 200-light dynamo which will be driven from engines of appropriate power by rope connection. The small plant will be used for all-night lighting, and the engine to which it is connected is being made of very large size in proportion to allow the carrying of a very low steam pressure by the night watchman. They are also wiring up the building for between twelve and thirteen hundred lights.

Queen & Company, of Philadelphia, are making a great drive with their Cardew Voltmeters, which they say are as reliable as ever, and guaranteed accurate to 1 per cent. Desiring to reduce the stock of these goods, which is unusually large, they announce a special cut in prices to hold good only until Jan. 1st. It will pay interested parties, especially central station managers, to correspond with them and secure a copy of circular No. 405, which gives further particulars.

The Standard Electric Company are receiving a large number of orders for their new time cut-out for arc and incandescent circuits. They will have a new double pole device ready for the market in about ten days.

The Helios Electric Company are greatly increasing their plant owing to the demand for the Helios arc lamp.

NEW ENGLAND NOTES.

The Jewell Belting Company, of Hartford, have recently made the following sales of their well-known dynamo belts:—Suburban Electric Light Company, Elizabeth, N. J., one 42-inch double; West Side Railroad Company, Elmira, N. Y., complete outfit of belts; United Electric Company, Springfield, Mass., one 24-inch double; Hudson Electric Light Company, Hoboken, N. J., one 48-inch double and complete outfit of belts; North New York Electric Light Company, New York, two 48-inch double belts; Thomson-Houston Electric Company, of New York, N. Y., one 58-inch three ply; Hartford Electric Light Company, Hartford, one 28-inch double; and Jersey City and Bergen Railroad Company, Jersey City, N. J., three 27-inch double.

Waterhouse, Gamble & Company of Hartford, Conn., formerly Waterhouse Brothers, have opened a new office at 45 Broadway, New York, under the management of Mr. Wm. T. Partridge, of that city. This firm has now associated with it Mr. James N. Gamble, of Cincinnati, O., and Mr. James T. Partridge, and has opened the New York office for the purpose of largely increasing its business. The Waterhouse arc lamp for arc and incandescent circuit has been well received, and has attained a most marked success, and now that Mr. Waterhouse has connected with him two such eminently successful business men as Messrs. Gamble and Partridge, a large increase in their business is expected and is sure to follow.

The Pettingell-Andrews Company, of Boston, have just been appointed exclusive agents in the States of Connecticut, Vermont, Massachusetts and Rhode Island, for the Interior Conduit and Insulation Company, of New York, and will hereafter carry a full line of their conduit and fittings for immediate supply. They will also act as agents in these States for the new Lundell power motors manufactured by the Interior Conduit Company. The Pettingell-Andrews Company recently bought out the entire stock of the Eastern Electric Supply Company, and are enlarging their electric railway and house goods department, in order to accommodate the unusually brisk demand for goods.

The Campbell Electrical Supply Company, of 104 High street, Boston, have just issued a new price-list of "Century" wires and products, having cancelled the contract with their agent for the manufacture of the "T. Z. R." wires. Their "Century" wires, which can now be purchased at first hands, are made according to the original formulas of the celebrated "T. Z. R." with important improvements recently made by Mr. Campbell, the original inventor.

The Berlin Iron Bridge Company, of East Berlin, Conn., have taken the contract for a new machine shop to be built at Newport News, Va., for E. C. Hillyer & Company. The building will be 82 feet in width, divided into a central portion 40 feet between crane girder columns, with a wing on each side 21 feet in width. The wings will be two stories high, the balcony floor being used for light work. The central portion of the building will be controlled by a 20-ton traveling crane.

The Beacon Vacuum Pump and Electrical Company, of Boston, are making a rather important announcement in their recent advertisements, in which they state that they have reduced the price of the Beacon 16 c. p. incandescent lamps to 35 cents, in lots of not less than 200. They state that they are enabled to make this reduction by the continued perfection of their special methods of manufacture, whereby they are enabled to make important savings, which they are willing to divide with their customers.

The Massachusetts Chemical Company, of Boston, manufacturers of Insullac, which has found favor with most electrical manufacturing companies, report that a recent test made on a large field coil wound with Insullac showed an insulation resistance of 23 megohms without leaking, a result which can hardly be achieved by using the ordinary shellacs.

The Shawmut Fuse Wire Company, of Boston, have, owing to the large increase in their business during the past few months, been forced to take larger quarters, and have removed to 161 High street, where they will have largely increased facilities for filling promptly all orders for tested fuse wire and links.

Mr. M. R. Neily, who was formerly connected with the Boston Electric Company, has commenced business under his own name, with headquarters at 10 Indiana Place, and has been awarded several good contracts for construction business.

Mr. Maybin W. Brown, 620 Atlantic avenue, Boston, has been appointed exclusive agent for Boston and suburban districts of the famous Salamander wire, manufactured by the Washburn and Moen Manufacturing Company of Worcester, Mass.

Mr. W. H. Francis, well known as one of the firm of Paine & Francis, not now in existence, has become connected with the Edison Electric Illuminating Company, of Boston, and will take charge of a special department.

Mr. F. R. Hart, of the Massachusetts Electrical Engineering Company, of Boston, has sailed for the United States of Colombia, where he will remain for a few months on business.

Google

WESTERN NOTES.

Mr. Edward H. Fox, Western agent of the Phœnix Glass Company, Ceylon Building, 19 and 21 Wabash avenue, corner Lake street, Chicago, has issued the following announcement to the trade: "Owing to the extensive increase in our designs and styles, we have found it necessary to open a salesroom in this city for the convenience of our Western trade. Our new styles of electric, gas and kerosene glassware, in cut, etched and colored, for 1892, are now ready, and will well repay an examination. The styles are new and novel and superior to anything before shown. I shall be at the rooms daily, from two to five o'clock p. m. until January 10. Other appointments can be made, if desired, by reasonable notification, the latter part of each month. I shall visit the trade in other cities as heretofore, and my residence in Chicago will enable me to call upon you often. I feel assured that it will be to your interest to call and examine our new lines."

Taylor, Goodhue & Ames have issued a very tastefully gotten up brochure regarding the Burton electric heaters, for which they are the selling agents. It is very attractively arranged showing the plan of wiring, pictures of the heaters, the Pullman double decked car equipped with same; gives some figures on the cost of operating and a number of very flattering testimonials. They also take occasion to quote the article which appeared in the The Electrical Engineer, July 29, 1892 on "Advances in Electric Heating," by W. R. B. Willcox, and give an extract of the report of the committee on Science and Arts of the Franklin Institute of Philadelphia on the Burton Electric Heater. It deals very thoroughly with the advantages of the Burton heaters and contains quite a fund of information regarding them.

Mr. John A. Grier, the well-known electrical and mechanical engineer of Philadelphia, has changed his residence to Chicago. He has equipped his home at Englewood with electricity in a very complete manner. Among the other novelties is a push button at the front door which lights up the newel post in the hall or puts it out. A double push upstairs also controls the newel post, operating a Russell automatic switch. A three-point switch in the hall turns on lights in both the upper and the lower hall and a three-point switch on the second floor controls the same lights. He has also fitted up a laboratory for experimental work, in his basement. His two sons, Mr. Thos. G. Grier and Edw. R. Grier are already well known in Chicago electrical circles.

The Hazelton Tripod Boiler Company, has made an assignment in the county court to the secretary of the company, Geo. W. Griffin, for the benefit of the creditors. Mr. C. Holmes, the well-known railway man, formerly president of the Chicago City Railway Company, is president of this company. It is stated by the attorneys that the assets are something like $65,000, while the liabilities are about $25,000. The direct cause of the assignment is a $1,500 judgment obtained in the United States Courts in favor of the Linden Steel Company of Pittsburg.

The Electrical Supply Company, Chicago, general Western agents for the Stanley transformers, have recently closed contracts for immediate delivery to one of the largest alternating stations in the West for 690 transformers, amounting to over $45,000. The Stanley transformers are to replace those at present in use, and the exchange was made on account of the small leakage current of the Stanley, showing a saving in operating expenses so great as to make it economical to throw out the old transformers and substitute new ones.

The Oliver P. Clay Company, Cleveland, Ohio, 51 Scranton avenue, are pushing their Baldwin soot suckers and vacuum boiler tube cleaners for electric light and railway plants, and name the following recent sales of soot suckers: Sioux City, Ia., Electric Company; LaPorte, Ind., Electric Company; Key West, Fla., Gas and Electric Light Company; Inter-State Complete Electric Construction Company, St. Louis, Mo.; South Bend, Ind., Electric Company. The literature disseminated by the concern is of the most amusing and convincing character.

Mr. D. H. Ogden, who is well known in electrical circles in the West has been appointed Western manager of the *Electrical World*, Mr. Fred De Land having resigned to go into other business. Mr. Ogden has been associated with electrical business for many years, having been with the Western Union Telegraph Company and later with the Bell Telephone Company as general manager of the Iowa systems. For the past two years he has been connected with the *Western Electrician*, during the latter part of the time as business manager.

The Electric Appliance Company have just rounded out their first business year, and report that the results have been highly satisfactory in every way. They will begin the new year by calling the attention of the trade to several recently acquired specialties of considerable interest. Their facilities have been increased in every direction, and the prospects of a heavy busines for the coming year are very flattering.

The Railway Equipment Company are extensively busy in all their lines of electric railway supplies. They have recently closed contracts for overhead equipment with the Sandusky, Huron and Milan electric street railways, the Webb City, Mo., electric railway and the Huntington, W. Va., railway. The demand for the Ahearn electric heating appliances is very brisk and increasing right along.

The Department of Electricity has been removed from the old offices in the Rand-McNally Building to the new quarters in the Electricity Building. The installation of the office was personally superintended by Prof. J. P. Barrett, assisted by secretary Hornsby. The work of the department will now be more vigorously pushed forward than ever and preparation for exhibits completed with despatch.

The Enterprise Electric Company are moving into their large new store, 307 Dearborn street, Chicago, having already outgrown their old quarters at 313 and 315. This is a good showing for the first six months. The company expect to meet with equal success, if not greater, in their new home and believe that their increased facilities will be a great element in their further growth.

Mr. R. Fleming, superintendent of the Rockford Electric Manufacturing Company, of Rockford, Ill., spent two or three days in Chicago last week on business for his company. Mr. Fleming reports being very busy and that the shop is running full-handed turning out the Rockford dynamos and motors.

"The Electric Spark" has been published under the auspices of the Electrical Supply Company for several months, but announces that the paper will be hereafter issued as an independent literary journal. A company has been incorporated with $25,000 capital to back the enterprise.

A. M. Morse & Co., St. Louis, among other recent sales have furnished a 300 h. p. cross compound condensing Buckeye engine to the Laclede Gas Company for their Mound street station, furnishing power for incandescent lighting.

In olden times the world looked to Athens for light—now Athens looks to Chicago for means of metering its light. Thus George Cutter interprets a recent order from Athens, Greece, for a batch of lamp-hour recorders.

The Russell Automatic Switch is meeting with success wherever it has been used. The architects of Denver at their recent exhibition, used the switch as a drawing card.

Mr. Geo. Cutter, The Rookery, Chicago, has been appointed agent for the porcelain specialties manufactured by Pass & Seymour of Syracuse.

CANADIAN NOTES.

The Royal Electric Company, of Montreal, has purchased an adjoining property of equal extent to the land occupied by its factory and station on Wellington street. It was the intention of the company to erect buildings upon this property, at once to be used as additions to the factory and station, but owing to the lateness of the season this has been postponed till next spring. The new station will be devoted to incandescent lighting, and will have a capacity of 50,000 lights to begin with, making, with the present stations, a total capacity of 125,000 incandescent lights, 1,500 arc lights, and 200 h. p. for power. Its equipment will consist of five 1,000 h. p. vertical compound engines, each belted to two 5,000 light alternators, designed by Mr. Fred Thomson, the electrician of the company. A special feature of these alternators is the embedding of the armature wire in the armature core so that no binding wires are required. An alternator similar to these is being constructed for the Ottawa Electric Light Company, of Ottawa, and a smaller one for the Quebec and Levis Electric Light Company, of Quebec.

The Quebec and Levis Electric Light Co. has purchased for $235,000 the entire water power of the Montmorency Falls together with the buildings and plant at present there. These falls, which are located about six miles in a direct line from the city of Quebec, have a descent of 260 feet and it is estimated will yield in the neighborhood of 18,000 h. p. Heretofore the company hired the portion of this power necessary to operate its station, but under the able management of Mr. S. Mohr, its business has increased to such an extent that more power was required, and in in order to secure this the entire water power of the falls was purchased. It is the intention of the company to erect a new power house and station and to fully utilize the power of the falls.

Electrical Engineer.

VOL. XIV. DECEMBER 28 1892. No. 243.

INSULATION RESISTANCE OF COTTON AND SILK COVERED WIRES. [1]

BY

Thatcher T. P. Luquer, C.E.

AN enormous quantity of cotton covered and silk covered wire is used in the manufacture of dynamos, telegraph instruments and other electrical apparatus. Nevertheless, little or nothing has been published regarding the actual, or even comparative, insulating qualities of cotton and silk coverings. The great difference in the cost of, and space occupied by, cotton and silk coverings makes it very important to know their relative insulating value. In a similar way the difference between single and double cotton coverings in cost and space is also important.

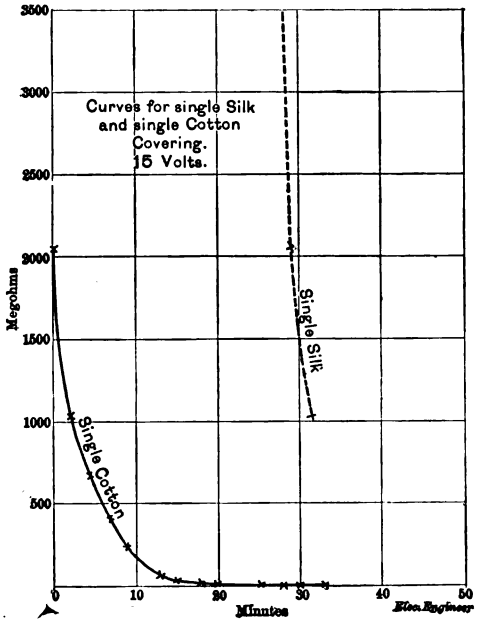

FIG. 1.

The kind of wire tested was that known as "magnet wire," consisting of copper wire covered with one or two layers of cotton or silk and called respectively "single" and "double" covered. The size of the wire itself in every test was No. 10 A. W. G., being .102 inch (102 mils) in diameter and the thickness of insulation (one side)

was .004 inch for single silk
" .005 " " " cotton
and .009 " " double "

The experiments consisted in making tests on the insulation resistance between two disconnected adjacent layers of wire wound on wooden spools 2 inches in diameter. The wire was wound on the spools on a lathe as evenly and with as uniform tension as possible. The coils were made 4 inches long. In order to observe the effect of shellac upon insulation, a spool of each kind of covered wire was treated with a coat of shellac between the two layers, and another coat over the outer layer. The spools having been wound with wire were baked in a drying oven at a temperature considerably above 212° F. for a time of about 2 hours, expelling in this way the moisture contained in the wood, wire covering, and shellac. The coils were then cooled in a bell jar to keep them from absorbing moisture. Both the plain and shellaced coils were thus treated.

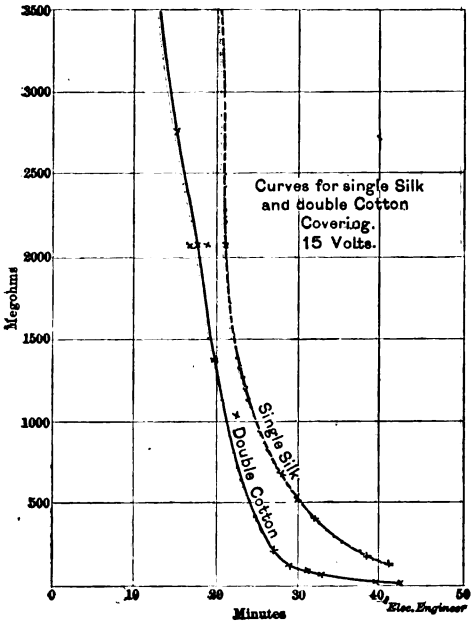

FIG. 2.

The coverings tested were single cotton, double cotton, and single silk. It seemed desirable, not only to determine the absolute difference in the insulation of the coverings, but also to observe the effect of moisture on the insulation

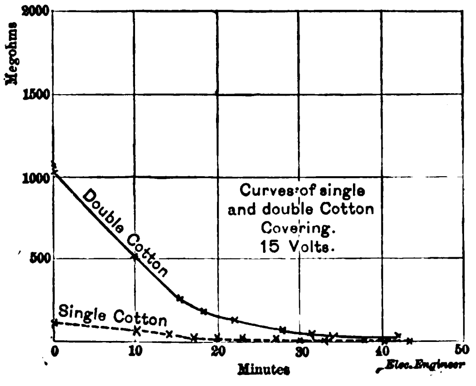

FIG. 3.

---

[1] Electrical Engineering Thesis, Columbia College.

resistance of the different coverings, so that it might be determined whether one kind of covering was inherently better than the others, or whether its superiority was due to a smaller hygroscopic tendency.

In order to test the coils when affected by moisture, all tests were made with the coils placed under a bell jar containing a wet and dry bulb hygrometer for measuring the humidity, and provided with an inlet through which steam could be introduced at will.

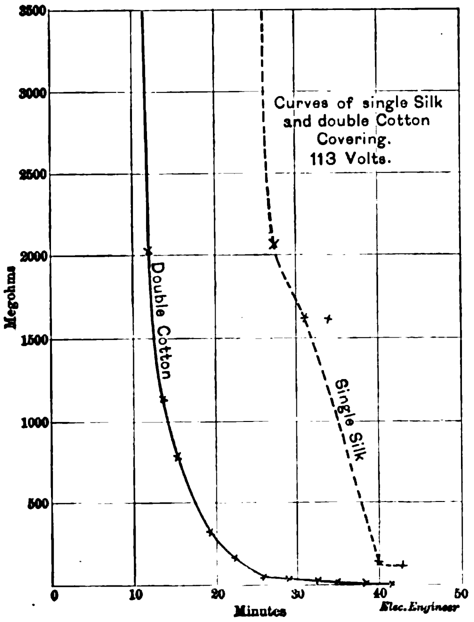

FIG. 4.

Each experiment consisted in testing, alternately, the insulation resistance of two different coils placed side by side under the bell jar. They were, therefore, always under similar conditions, even of varying humidity, and so it was determined to neglect the humidity in drawing curves to show the decrease of insulation resistance in moist air, and to use as the co-ordinates of the curves, the resistance and the time. As, however, the humidity had some effect on the rapidity of decrease of resistance the percentage of moisture in the bell jar was brought to a high point rapidly (about 98 per cent.) and then kept as constant as possible throughout the test.

The method used for measuring the insulation resistance was the ordinary one by direct deflection, using the following formula, which is condensed from the exact formula for this method by throwing out battery resistance, etc., which, in measuring megohms can be neglected.

$$X_{\text{meg.}} = \frac{\delta_R}{\delta_C} 10,$$

in which

$X_{\text{meg.}}$ = insulation resistance in megohms.

δ_R = galvanometer deflection for the known resistance of 100,000 ohms with 15 cells of chloride of silver battery and $\frac{1}{99}$ shunt.

δ_C = galvanometer deflection for the coil being tested with 15 cells of battery and no shunt.

If the $\frac{1}{9}$ shunt became necessary for use on the coil the result had to be divided by 10 and if the $\frac{1}{99}$ shunt became necessary the second member of the above formula had to be divided by 100. Some tests were made by using the electric light circuit of about 115 volts, putting the $\frac{1}{999}$ shunt on the galvanometer for 100,000 ohms, and putting 100,000 ohms in series with the circuit as a precaution against accident.

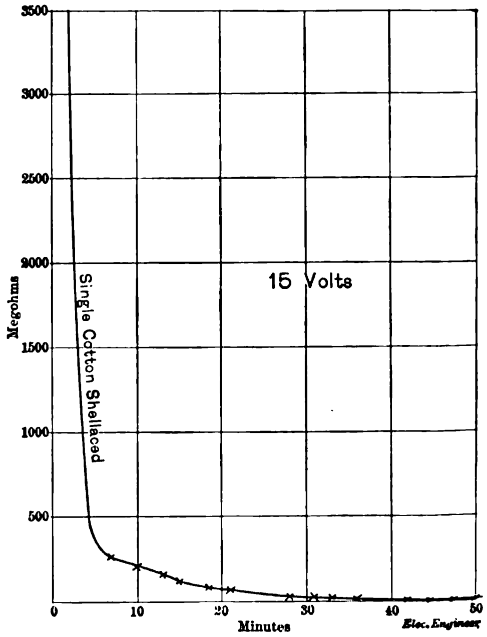
Each experiment is illustrated by a diagram giving the curves for the two coils tested. The curves on different diagrams cannot be strictly compared because the conditions of the coils in different experiments were not exactly similar. However, in order to connect the experiments the coils were interchanged, comparing each two coils in a separate experiment.

To proceed with a discussion of the experiments. Fig. 1 shows the difference between the insulation resistance of single cotton and and single silk coverings. The silk is seen, at once, to be far superior to the cotton, for even when dry the ratio of the resistance is as ∞ (practically) to 2,000 megohms. When moisture attacks the coils the cotton feels it at once, dropping rapidly and steadily, while the silk resists its effects for over half an hour, at which time the insulation of the cotton is low. When the insulation of the silk began to fail, it dropped rapidly, but the conditions then had ceased to be practical, the coils having been exposed for over half an hour to an atmosphere nearly saturated with moisture.

From this comparison I think we can draw the inference that, in the first place, silk is inherently better than cotton as an insulator, for both coverings were single and of very nearly exactly the same thickness, and all the conditions to which the coils were exposed were as nearly the same as possible; and in the second place, that moisture affects the insulation of cotton much sooner and to a greater extent than that of silk, owing, undoubtedly, to a much greater hygroscopic tendency in the cotton.

Fig. 2 shows the comparison between double cotton and single silk coverings. The effect of doubling the thickness of the cotton between the layers of wire is, as was to be expected, sufficient to greatly increase the effectiveness of the insulation, making it when dry about as good as silk. Moisture does not affect the insulation of the double cotton so soon or so greatly as in the case of single cotton (as shown in a following case) and the cotton curve compares quite favorably with the silk, considering the severe conditions of moisture imposed.

Fig. 3 shows the comparison between single and double cotton coverings. The initial resistances of the coverings are very low owing to the coils having been cooled in the air of the laboratory instead of under a bell lar, as in the case of the others. This defect in cooling was unavoidable, and no opportunity was found, unfortunately, to repeat the experiment. The value of these two particular



The Curve for Silk is a Line Parallel to the Axis of Time at an Infinite Distance (Practically.)

FIG. 5.

curves, for comparison of the one with the other is not, however, seriously impaired. We see, as before noted, that the double cotton is very much better than the single

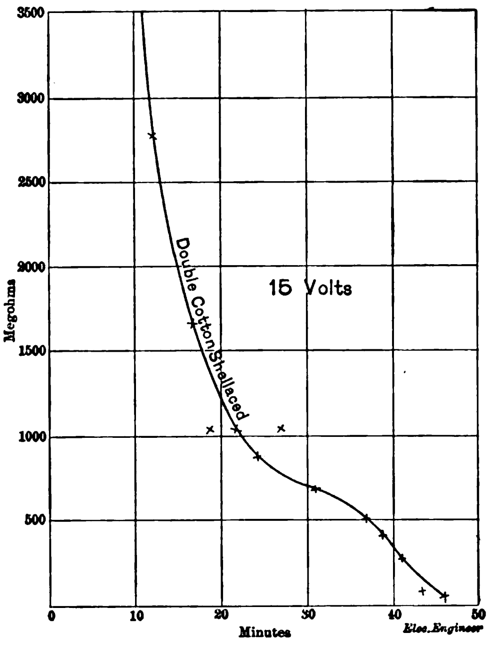


FIG. 6.

The Curve for Silk is a Line Parallel to the Axis of Time at an Infinite Distance (Practically).

cotton throughout the experiment, and shows more resistance to the effect of moisture than the single.

Fig. 4 shows a comparison of the curves for single silk and double cotton coverings subjected to the effect of 113 volts. We see that, when dry, the silk for this potential gives an insulation resistance of ∞ (practically), while the cotton, although very high, shows the effect of the strain and has a resistance of about 64,800 megohms. The cotton begins to feel the effect of moisture immediately, while the silk is apparently unaffected for over 15 minutes.

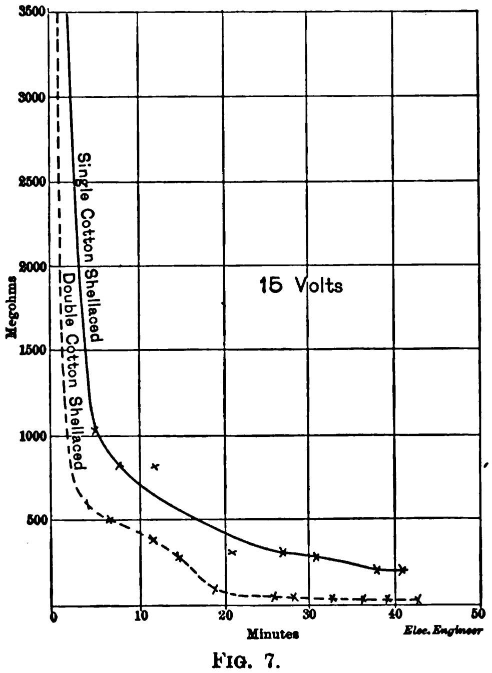

FIG. 7.

The cotton curve is regular, showing that the absorption of moisture goes on nearly uniformly, while the silk curve is erratic, the curve descending with jumps when steam is admitted to the bell jar, and absorption almost stopping at other times.

The conclusions that may be drawn from this first series of experiments are as follows:

1. Silk is inherently a much better insulator than cotton.
2. Silk is also a much better insulator than cotton because of its greater resistance to the effect of moisture, that is, it has a smaller hygroscopic tendency.
3. Double cotton covering is practically as good as single silk for ordinary voltages up to 120 volts, providing it is very dry. Subjected to the influence of moisture it fails more rapidly and to a greater extent than silk, but holds its own much better than single cotton.
4. Single cotton, even when dry, is a much poorer insulation than either silk or double cotton.
5. Silk still shows a good insulation resistance when, after half an hour's soaking in moist air, the cotton coverings have almost failed entirely.

We come now to the curves illustrating the experiments made on shellaced coils. Fig. 5 shows the curves for shellaced single silk and shellaced single cotton coverings. We see that, with the shellac to protect it from the moisture, the insulation resistance of the silk remains 8 (practically) throughout the test. The cotton, benefited to some extent by the shellac, starts with a better insulation resistance than before, but fails immediately and rapidly. The effect of the shellac on the cotton is simply to raise the curve throughout, but not to change its character.

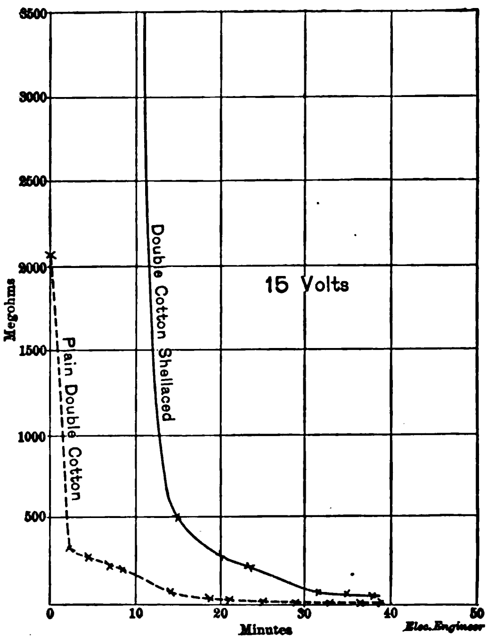

FIG. 8.

Fig. 6 gives the curves for shellaced silk and shellaced double cotton coverings. As in the preceding test the shellac enables the silk to show an insulation resistance of ∞ (practically) throughout the experiment. The cotton has an initial resistance of ∞ (practically,) and does not fail immediately. It is, however, affected and drops in the usual curve, only not as regularly or as much as without shellac.

Fig. 7 shows the comparison between shellaced single cotton and shellaced double cotton coverings. These coils had been kept rather longer after baking before being tested than in the other cases and, consequently, had absorbed a small amount of moisture, reducing the resistance of the double cotton coil from ∞ (practically) to somewhat over 4000 megohms. The comparison, however, is not impaired, as both cooled the same length of time and under the same conditions. As usual, the double cotton shows a better curve than the single cotton.

Fig. 8 shows the results of some experiments made directly to discover the effect of shellac on insulation, more particularly the comparison between double cotton shellaced and double cotton coverings unshellaced.

These curves show, in the first place, that shellac increases directly the insulation resistance of cotton, and in the second place that it helps the cotton to resist the effect of moisture to some extent by offering a barrier between the cotton and the moisture which breaks it down comparatively slowly. The conclusions that we may draw from the series of experiments on shellaced coils are :

1. Again the inherent superiority of silk compared with cotton as an insulator.
2. The continued superiority of double cotton over single cotton.
3. The apparent equality between double shellaced cotton and plain silk, as shown by comparing the silk curves in Figs. 1 and 2 with the cotton curves in Figs. 6 and 7.
4. Single cotton, plain or shellaced does not compare favorably with either double cotton or silk, plain or shellaced.
5. That shellac increases the insulation properties of both silk and cotton.

The experiments show that the insulation resistance of cotton, both single and double, diminishes under the strain of higher voltages (115 volts), while silk is not affected. The experiments also show that shellac enables cotton, apparently, to withstand the higher voltages under which, before, it showed signs of failure.

I have drawn conclusions in the preceding pages from what may seem, to some, rather insufficient data, but I feel justified in drawing those conclusions because all the experiments tend to corroborate each other, there being no conflict between the curves constructed under similar conditions. In conclusion, the results may be summed up as follows :

1. Silk, shellaced, is the best insulator.
2. Silk, plain, is probably the next best, and is very good, although only .004 inch thick.
3. Double cotton, shellaced, is practically as good as plain silk for use with voltages below 120 volts, and probably higher ; but double cotton is over twice the thickness (.009 inch) of single silk (.004 inch).
4. Double cotton, plain, is the next best insulator, and is good.
5. Single cotton, shellaced, comes next and is not so good.
6. Single cotton, plain, is poor, although thicker (.005 inch) than silk.
7. It is advisable to use shellac on all cotton covered wires, taking care to thoroughly dry the shellaced coil.

ENTITIES, MAGNITUDES, QUANTITIES AND UNITS.[1]

BY E. HOSPITALIER.

CONFRONTED by the ever growing invasion of scientific neologism, neologism which at first answered to a real need, for new ideas require new words and new definitions, it seems useful to offer a few considerations with the view of reaching an understanding respecting the principles which should govern the formation of the scientific language of the future, which it is to be hoped for the sake of posterity, will be more logical and coherent than the language of to-day. My readers will decide for themselves whether the considerations about to be presented will be useful in attaining the desired end: Unity in scientific terminology.

Entity which constitutes the being, the essence, the nature of a thing, is the first vague idea we have. When the idea of entity is acquired, that of magnitude, susceptible of increase or diminution soon completes it and from this, the idea of physical quantity follows. When the idea of physical quantities of the same kind but of different magnitudes is perfectly clear, then, and then only the unit appears, a quantity of a certain magnitude, serving as the common measure of magnitudes of all quantities of the same kind.

An example will better explain my meaning. The idea of the temperature entity is very old, but for a long time there was no precise idea of its magnitude. In a work published in 1542 in Venice, entitled, "Summa perfectionis Magisterii," is found the complaints of Geber as early as the eighth century, concerning the great difficulties which are met with in conducting operations at high temperatures because heat—the distinction between heat and temperature no longer exists—cannot be measured, *quoniam non est res ignis, quæ mensuari possit.* The physical temperature entity became a physical quantity only when the measurement of it was achieved by the invention of apparatus for comparison ; then followed the *units*, still more arbitrary and of an empiricism unworthy of the progress of science. What has just been said in relation to temperature has happened over again several times during a century in relation to the electrical entities. For each of them the idea of magnitude, then that of physical quantity, have preceded the idea of the *unit*, which came last of all.

The existence of a physical quantity is then independent of that of a unit of measure, and the idea of this unit came only after the clear idea of the quantity itself. There results from this that a physical quantity can be strictly defined only by bringing into its definition physical quantities, and physical quantities only.

The physical quantity is international, immutable in its essence, independent of the units of measure which are, on the contrary, national, varying according to the caprices of individuals and of governments. In defining each physical quantity without the units which are used as its common measure, its precision and its internationality is preserved, leaving each entirely free to choose the unit which is most convenient for each nation or for each application.

These important distinctions between an entity, a magnitude, a quantity and a unit, have a direct application in new definitions every time there is a new entity to be defined. We must not forget that the definition of a physical quantity is not deduced from its unit of measure, but, on the contrary, that the unit of measure is deduced from the definition of the physical quantity. The Congress of 1889 made an error of this kind, an error sanctioned by vote, in spite of my protestation, in relation to the *frequency of an alternating current.*

The English commit an analogous mistake by defining magnetic induction as the number of lines of force per cm.,[2] the French by defining the power of a machine, its work per second, etc. In acting thus, a physical quantity and a unit are associated; the product of this association is a hybrid, neither physical quantity nor unit, the least inconvenience of which is to completely falsify right ideas of the relations between physical quantities and to establish an inextricable confusion between physical quantities and the units which are used as their common measure.

For the same reason only the units of the quantities which define that quantity should enter into the definition of a unit of measure of a given quantity. Thus for example, the English persist in expressing specific resistances in ohms per cm.,[3] on the assumption that the specific resistance of a substance is the resistance of a cube of 1 cm. cross-section between two opposite faces. Specific resistance cannot be measured in ohms per cm.,[4] it is the product of a length and a resistance and should be measured in centimetre-ohms.

These general ideas are unfortunately almost always misunderstood, and this is the reason that we often see in the memoirs of learned societies of the highest reputation, velocities and accelerations in metres, specific resistance in ohms, etc.

---

[1] From *L'Industrie Electrique*, Aug. 10, 1892. *Translated by F. R. C. Prescott.*

International congresses in my opinion would do a great and useful work in formulating once for all the general rules well stated; special definitions will be only the natural logical and systematic consequences, the application of which can be extended indefinitely in order to fulfil the new needs of the progress of science and the physical industries.

METHODS OF WIRING A BUILDING WITH CONDUIT.

BY

Paul C. Ascanyan

CERTAINLY so far as I know, no description has yet appeared in any electrical paper of the actual methods adopted in wiring one of the fine new modern office buildings, with the aid of conduit. This is a little singular, as conduit is already recognized as an indispensable feature by all our progressive and leading architects. With the object of giving an idea of the methods and practice now prevailing in this branch of the art, I venture to call the attention of the readers of THE ELECTRICAL ENGINEER to the work recently finished under my supervision in the Mills Building, San Francisco. I think the details will be found of general technical interest.

The Mills Building of San Francisco, is situated on the corner of Montgomery and Bush streets. It is thoroughly fire-proof, and is constructed of buff brick. It is ten stories high in the main building with an additional two stories above. It is 160 feet high with a frontage of 160 feet on Montgomery street and a depth of 140 feet on Bush street. It has some 420 rooms or offices, all of which are light and habitable, the inner ones being lighted by a spacious court in the centre of the building, the walls of which are of white glazed brick. There are about 2,100 outlets in the building, which supply some 3,200 lights. The supply of current is obtained from an isolated plant in the basement, which includes three No. 32 Edison machines. The conductors from these dynamos are polished copper rods, which cross the ceiling of the basement to the switchboard, located at the back of the engine-room and constructed of polished marble, presenting a fine appearance with its polished brass switches and instruments.

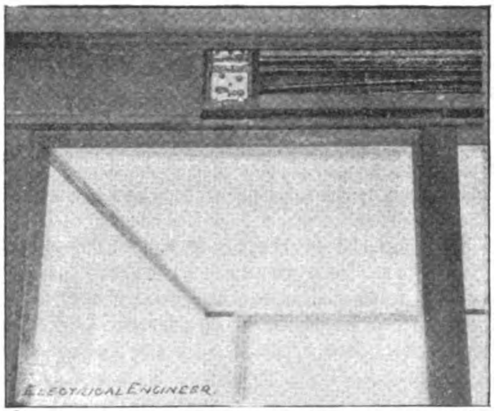

FIG. 1.

Running on the ceiling from the switchboard to the pipe shaft where they ascend are 24 tubes of one inch and one inch and a quarter inside diameter conduit which constitute the feeders for the building; two tubes feeding each floor and terminating in a cut-out box located in a toilet closet by the shaft. In these boxes are the switches and cut-outs which control the feeders for that floor, which are located in a space provided for them around the corridors on either side. These feeders, six in number, are ⅝ and ¾ inch inside diameter tubes. They are afterwards covered over with an oak moulding which constitutes the cornice and corresponds with the general interior finish of the building, of the style seen in Fig. 1.

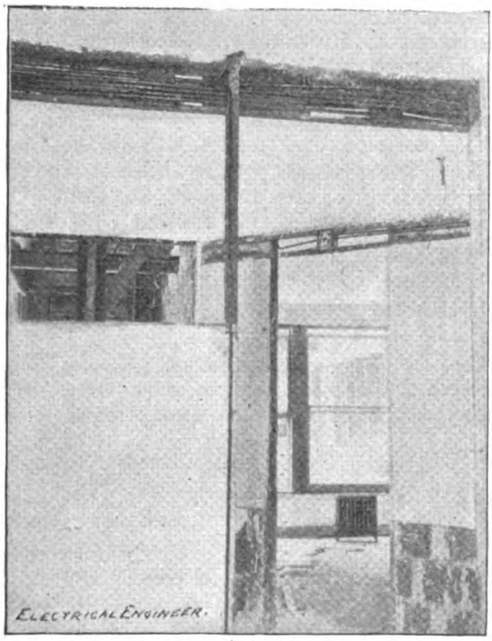

FIG. 2.

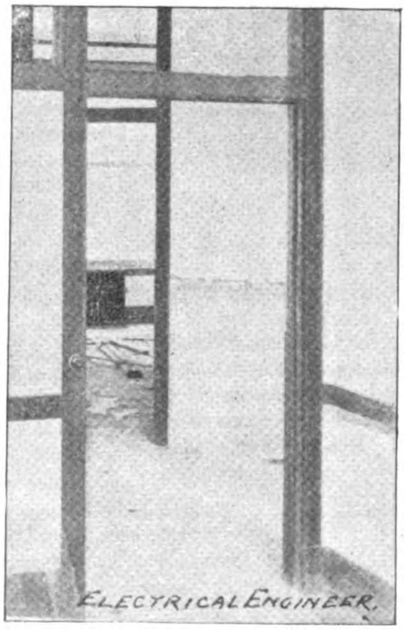

FIG. 3.

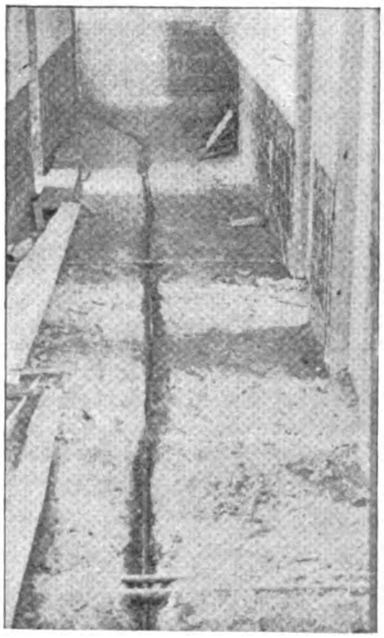

FIG. 4.

The mains which feed the offices are intersected by a cut-out, one of which is located in front of every office, Fig. 1, and is concealed behind a door in the cornice. From this cut-out the office circuit which is composed of ½ inch tube, coupled and telescoped within a ¾ inch conduit, ramifies. The room circuits are run above the tiling of the office they feed, Fig. 2, and run generally to a centre and two side outlets, being controlled by a switch conveniently located in the oak finish by the door as shown in Fig. 3.

The hall circuits are upon a separate system with all other public lights. They are also double tubes telescoped, and are fed through a cut-out located in a like manner behind the cornice shown in Fig. 2, to the left. These hall circuits are protected in the following manner: The earth and ashes used for deadening are removed from around the tube, which is then raised on small pieces of conduit laid crosswise beneath it. The space thus made, Fig. 4, is then filled in with plaster of paris, which forms a cheap and ample protection from acids and alkalies which might percolate through the cement, upon which a marble flooring is laid. The method of laying in a room is shown in Fig. 5. All tubes are held in place by patent metal clips and all joints are made with metal couplings corrugated and painted with P. & B. paint. The conduit employed is the black unarmored tubing made by the Interior Conduit & Insulation Company, of New York. In all some 18 miles consisting of ¼, ⅜, ⅝, ¾, 1 inch and 1¼ inch inside diameter tubes have been used. The wire used for branch circuits is the standard twin conductor of the Interior Conduit & Insulation Company, No. 14 B. & S. All mains and feeders are of flexible cable. No expense or trouble has been spared by the Edison General Electric Company of San Francisco to make this a fine conduit installation. It has been stated by experts that if a large enough crew were employed every wire in the building could be withdrawn and new ones inserted in less than ten minutes. The cost of wiring with the complete conduit system in this building was about the same as the cost for the Mills Building in New York, which was wired in the old manner with circuits laid in the plaster merely.

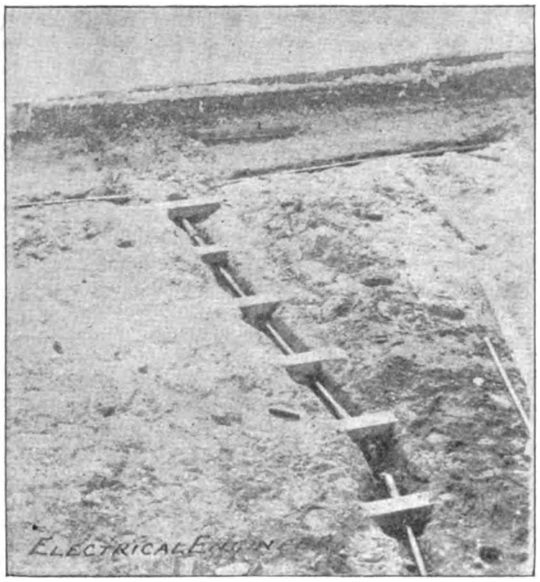

FIG. 5.

THE FRANKFORT EXHIBITION OF 1891.

THE managing committee of this exhibition recently issued its final financial statement. The total disbursements were $322,000, and the total receipts $346,000, thus leaving a balance profit of $24,000. Of this balance 15 per cent. was handed over to Herr Oscar von Miller, in accordance with his agreement; and the surplus was devoted to repaying subsidizers and exhibitors, the latter obtaining about 25 per cent. of the sums originally paid by them for space.

EMPIRICAL FORMULÆ FOR H-B CURVES OF MAGNETIZATION.

BY

Chas E Emery

THIS article is the outcome of a request by the editor of THE ELECTRICAL ENGINEER that the writer would, so far as possible, abridge Part II of his recent paper embracing the above subject,[1] and add some examples of the application of the formulæ.

Empirical formulæ for H-B curves of magnetization enable equations to be completed involving varying values of H or B, and thereby permit the application of the mathematical laws of maxima and minima, with all the important conditions of the problem included. Such formulæ also serve to correct errors in particular records by general comparison through the whole range of observations, and at the same time furnish a more ready and accurate means than arithmetical interpolations to obtain intermediate values really dependent upon complex functions. While many approximate formulæ have been suggested for the purpose, that of Frölich has been generally employed in the following form:[2]

$$(11) \qquad B = \frac{H}{a + b\,H}.$$

For ordinary magnetizations this equation, divided by B, gives the formula of Kennelly for the reluctance, but for high magnetizations H should be added to the second member of above equation, and the reluctance applies to the metallic induction.[3] The equation only contains two constants and can only be passed through any two points of a curve. It is frequently, therefore, unsatisfactory except near the points of application. Fig. 3 shows an application of this curve to Rowland's experiments, by substituting the reluctance constants (a = 0.0001, b = 0.000058), given by Kennelly, in Eq. 11, which shows that although the Frölich function shows no very great departure from the experimental curve within the limits illustrated, still the elements are quite different and the two curves are separating rapidly at the higher limit. One application is, however, made of the Frölich function by the writer, in the form following, to show the permeability μ as derived from Eq. 11, by dividing through by H.

$$(11a) \qquad \mu = \frac{10^{n}}{a + b\,H}.$$

The writer makes the applications in most cases to an equation of an hyperbola in the form (misprinted in the original.)

$$(15) \qquad B = c - \frac{a}{b + H}.$$

There being three constants in this equation, the resulting curve can be passed through any three points of any experimental curve, and greater accuracy obtained by applying the curve twice, once from near the origin to some definite point above the abrupt turn, and again for the remaining portion of the curve. It is found that the two curves thus obtained coincide practically for quite a little distance. No attempt has been made to apply the formula to the sharp bend near the origin marking the excitation necessary to cause the molecular magnets to turn toward approximate parallelism, but the application can commence at excitations of two to five, which is as low as is ordinarily required in practice.

---

[1] The paper was read at the Chicago meeting of the American Institute of Electrical Engineers, and entitled "Rational and Empirical Formulæ Showing the Relation between the Exciting force (H) and the Resulting Magnetization (B)." See abstract of Part I, THE ELECTRICAL ENGINEER, Aug. 17, 1892).

[2] The equations and diagrams are numbered as they appear in the original paper.

[3] "Magnetic Reluctance." THE ELECTRICAL ENGINEER, June 15, 1892.

There is also one application of an equation of a straight line in the following form :

$$B = a + b\,H. \qquad (52)$$

The values of the constants for the various applications of the formulæ in the original paper are shown in Table O. Column 1 shows the numbers of the original equations and column 7 the numbers given herein of the equations showing the form of the function. In substituting the constants in either equation, the special values of H and B adapted thereto should be obtained from columns 4 and 5. The notation is explained by the headings of Table I.

The first application of Eq. 15 is made to experiments of Hopkinson on wrought iron, as stated in the well-known tables of S. P. Thompson. A number of these results are given in columns 7 and 9 of Table I. Column 8 of this table shows results obtained with a general formula on a rational basis, referred to in Part I of the author's paper.

A number of applications are made to results of experiments made under the direction of Dr. Nichols, at Cornell University, by Messrs. Thompson, Knight and Bacon, distinguished as the "Cornell" experiments.[4] These experiments show, what has probably been known to large manufacturers for some time, that some samples of steel either in the form of castings or plates, though showing less magnetism for low exciting forces than iron, really obtain a higher magnetization as the exciting forces are increased. A number of these curves are reproduced in Fig. 4 with the numbers in the original paper. The upper curve was however plotted from the Steinmetz experiments referred to below.

The quantities stated in Equations 18a and 18c for what is called a "compromise curve" are based, for the lower values, on the results obtained with mitis metal, Fig. 4, No. 22, while the higher values are made to correspond closely to those given by Hopkinson. This compromise curve provides for the fact that all samples of steel do not show higher magnetization than wrought iron, but always show lower results for low exciting forces. For ranges higher than shown by this formula, use Eqs. (17b) and (17d). Another compromise curve is given in Equations 18 f, g, h, i, based on Eq. 11a, from which results can be calculated even more readily than from an equation in the other form.

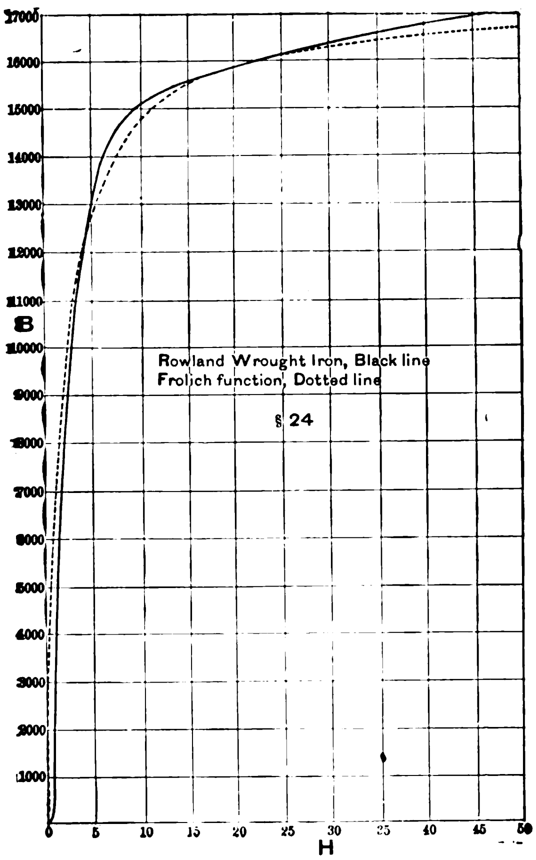

Fig. 3.

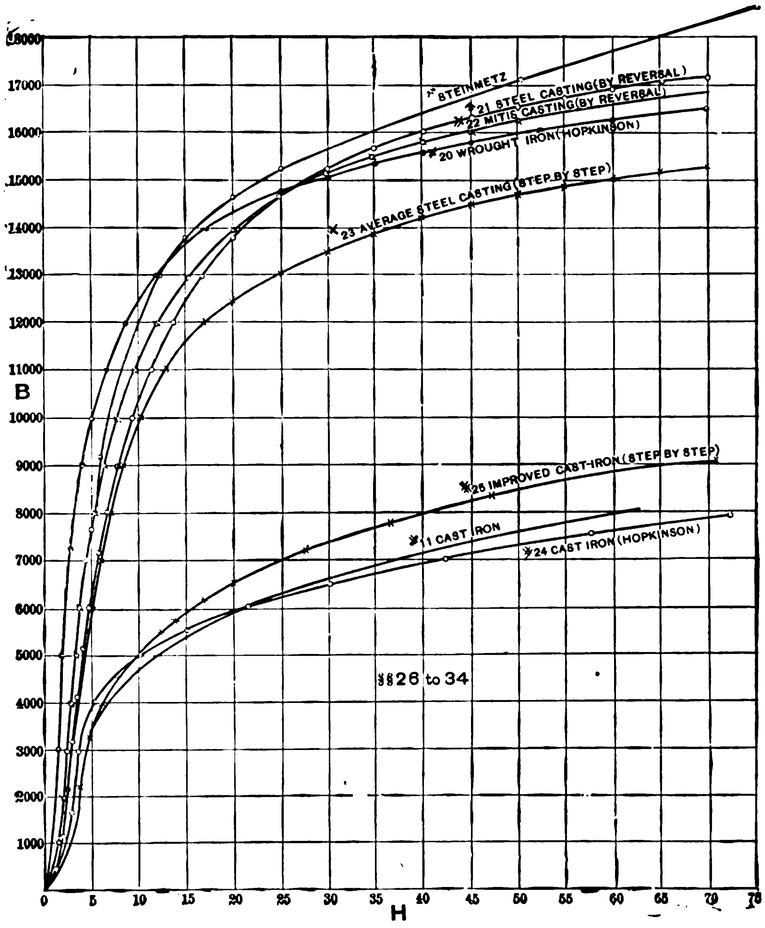

Fig. 4.

To show the application of these formulæ, let us suppose that for a current of 40 amperes a cross-section of field of 50 square inches and 500 series field turns have been provided ; that it is desirable to increase the field somewhat, and that the question arises which will best do it ; increasing the number of turns to 700 or increasing the cross-section of the field to 60 square inches. Referring to Table P, by dividing the number of turns (line 1) by the area (line 2) in each of the three cases, we obtain the number of turns per square inch (line 4); and multiplying these by the amperes (line 3) gives the ampere turns per square inch (line 5). If the field be of cast steel of best quality so as to equal wrought iron, and we select for illustration English instead of metric measure for use in this country, we may use Eq. (17d), Table O, as extending the range of Eq. (18c). Substituting the constants in Eq. (15) we have:

---

[4] "The Magnetic Permeability of Special Irons for Electrical Purposes." By M. E. Thompson. Transactions of the American Institute of Electrical Engineers, June, 1892.

$$(70) \qquad B_2 = \overset{(c)}{134292} - \frac{\overset{(a)}{28108425}}{\underset{(b)}{603.06 + H_3}}$$

Adding the value of b from the equation to $H_3 = 400$ from column 4, Table P, we obtain at once 1003 as the divisor in the equation. A mere inspection of Barlow's tables of reciprocals gives as the reciprocal of 1003, 997 divided by 10^6. Pointing off six places from the value of a, we obtain 28.108 to be multiplied by 997, and the result subtracted from the value of c, at once gives $B_2 = 106268$, as per line 6, Table P. This, multiplied by the area, line 2, gives a field, F, in line 7, equal to nearly 5¼ millions of lines. Proceeding in the same way for columns 5 and 6 of Table P, we find for column 5 that 700 field turns with cross-section of field maintained constant only increases the field in round numbers to 5⅔ millions, or 7 per cent., as per line 8, but by retaining 500 turns and increasing the cross-area of the field to 60 square inches, as per column 6, it will be seen that the value of B_2 does not reduce nearly as rapidly as the section increases, so the total field is in round numbers 6¼ millions, or is increased 17.6 per cent., a result 10.6 per cent. better than that obtainable by increasing the number of turns. The values of the field given are of course the total field. The magnetic flux or flow across the armature, must be found therefrom by the law of the magnetic circuit in the customary way. The possible modification of this law referred to in Part I will be examined hereafter. The above example will show the applicability of the formulæ, and it is believed that the results will be found much more satisfactory than interpolations from tables, or attempts to measure small curves.

In the original paper, Table I showed the results of experiments made by Mr. Steinmetz on the permeability of wrought iron in connection with his experiments on hysteresis.[5] The second part of this paper[6], however, stated the results of other experiments with the same material, differing considerably from the first, and in discussing this paper the writer pointed out that neither series agreed closely with experiments made by others, the first series being too high for the higher magnetizations, as shown on Fig. 4, and the others too low. The Steinmetz experiments with steel castings recorded in the latter paper, however, agree very well with what are herein called "compromise"

curves, based on the Cornell experiments, modified by the writer to agree with iron for the higher values, and moreover Mr. Steinmetz has found that these results are well represented through a wide range by a modification of the Fröhlich function, which in the form and with the notation used in this article, explained in the headings of the tables, is given in Equation 71 below. Equation 72, referring to inch measurements is also added.

$$(71) \qquad B = 1.257\, H_1 + \frac{10^7\, H_1}{535\, H_1 + 3500}$$

$$(72) \qquad B_2 = 1.257\, H_2 + \frac{10^7\, H_2}{82.93\, H_2 + 3500}$$

The results given by the Steinmetz formula are shown in column 5, Table I, and the opportunity has been embraced to present a number of comparisons of various exciting forces and magnetizations stated in different terms. Equation 72 will of course give the results shown in column 6; except such slight variations as are due to dropping decimals in the constants. The results in column 5 from the Steinmetz formula will be found a little higher for low values of H and lower for the high values than the results of the Cornell experiments shown in Fig. 4. The Steinmetz experiments, therefore, do not show the superiority of steel for high magnetizations which appears from some of the Cornell experiments, but for this reason the formula is believed to be safe, like the compromise curves above given, as all samples of steel do not show this property. For $H_1 = 2{,}865$ the Steinmetz formula gives only 22,251 lines as compared with 24,650 found by Ewing for wrought iron, and the Steinmetz formula for average wrought iron is very much lower, giving only 20,790 lines.

WERNER VON SIEMENS.—BIOGRAPHICAL NOTES.

(From a Berlin Correspondent).

THE Atlantic Cable with the history of which the name of Werner von Siemens is so intimately connected has already given to the New World the news of the death of that great inventor and scientist. The black flag, and the imperial colors, at half mast, are flying over the factories at Charlottenburg and Berlin, but the whirr and hum of the machinery and the restless activity of that great industry which he helped to give the world goes on unceasingly.

Von Siemens died at his villa in the suburb of Charlottenburg, surrounded in his last hours by a large family circle. His 76th year would have been completed next week had it been his lot to have lived till then.

It is remarkable that his autobiography which was published only a few days ago should be quoted almost for the first time in his necrology. The modest story of his own life, the history of the development of his ideas (he hardly calls them inventions) will be a classic among the books of "Uncrowned Kings."

Werner von Siemens was, as the German press in their appreciative articles style him, a "self-made" man. The languages of this continent appear to have no expression for the phenomenon for they always use our word. "Self-made" men however are not alone the product of our Western civilization.

He was born in Lenthe near Hanover. His father was a farmer. At school in the Gymnasium of Lübeck he displayed a great talent for mathematics, and intended to become an architect. To this end he took private lessons in land surveying, but the necessary financial means for fitting himself for this calling not being at hand, he entered, at 18 years of age, the military service in the artillery.

In the Magdeburg garrison he attracted the attention of his superiors and was thereupon ordered to the Artillery and Engineering School at Berlin. Here he had some opportunities to lay the groundwork for his future researches. At the age of 2[illegible] he was ordered back again to Magdeburg where, in an improvised laboratory, he occupied the hours of an enforced leisure (he was confined in the fortress in consequence of a duel) in experimenting with galvanoplating. He took out his first patent on the results of this work.

His life as a young officer interfered with his efforts to follow his favorite studies, as he was transferred to the Wittenberg garrison, then to Spandau, and finally, in 1844, to the artillery workshops in Berlin. Then for the first time was Siemens enabled to connect himself with the scientific spirits of the time in Berlin, such as Helmholtz, Magnus, Brücke and du Bois-Reymond. At this time he met the mechanic, Halske, who helped him materially in the practical development of his ideas. During these years he was busy, among other things, with the measurement of speeds by the electric spark. He recognized, however, the great importance of the telegraph, and occupied himself largely in that direction, seeking especially the laws governing underground and submarine cables.

His first telegraph invention was an improvement in the Wheatstone instrument. In 1849, on the order of the Government, he built with entire success the first underground telegraph line from Berlin to Frankfort-on-the-Main, a distance of about 350 English miles. After preparing (in 1848) the harbor of Kiel with submarine mines provided with electric fuses (this was to prevent bombardment from the Danes) he retired from the military service and established with Halske the business which has assumed such enormous proportions.

Von Siemens was knighted by the old Emperor William. The present Emperor sent the family a telegram expressive of sympathy and high regard for the eminent work of the deceased. Empress Frederick and others of the royal family, also expressed their sympathy. The Electrotechnical Society, of Vienna, sent a delegation to attend the funeral.

Von Siemens leaves three sons, the two eldest of whom, Arnold and Wilhelm, have had the management of the business for some time past. The wife of Mr. Arnold Siemens is the daughter of Helmholtz. The late Sir William Siemens in London was a brother of the deceased. It was principally with Sir William and Frederick, another brother living in Dresden, that the well-known "Regenerative Principle" was developed by the deceased.

Hardly less known than the other brothers is a fourth, Karl Siemens, who stands at the head of the St. Petersburg firm of Siemens Brothers. The latter firm was established in 1850, and has supplied all Russia with the telegraph.

Siemens was present at the Frankfort Electrical Exhibition in 1891, during the Congress week.

The works of Siemens & Halske at Berlin are devoted to the manufacture of telephones, telegraphs, signals and other small apparatus, while the dynamos and other heavy work are made at the extensive works in the suburb of Charlottenburg.

December 7th, 1892.

AN ELECTRIC MAIL SYSTEM BETWEEN NEW YORK AND BROOKLYN.

THE U. S. Post Office Department has made arrangements to test the mail handling system of the Automatic Dispatch Company, between the cities. The plan which the department has agreed to test is the invention of Mr. A. Bryson, Jr., and is to be operated by the Automatic Dispatch Company, 12 Broadway, N. Y., of which G. M. Mudge is president and Oscar C. Wheeler is secretary. The transportation will be done by a miniature trolley railway, enclosed in a 16 inch square conduit. The mail matter will be placed in carriers of steel wire, four feet long and fourteen inches square, each carrier taking a pouch containing 3,000 faced and assorted letters, or an equal bulk of other classes of mail. In the end of each carrier or car is a small electric motor, taking the current from a wire running between the tracks. It is expected that the cars will run from office to office in about five minutes, and keep up an incessant delivery to and fro. The cutting off of power and all switching will be done automatically, so that the clerks at either end will merely have to load and start the cars. The conduits, if the present plans are carried out, will be suspended from the iron work of the bridge and of the elevated road on Adams street, Brooklyn. The company has agreed to assume all cost in this experiment. Mr. Bryson is now securing patents on some of the details, and is unwilling to exhibit his drawings at present.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 203 *Broadway, New York City.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. XIV. NEW YORK, DECEMBER 28, 1892. No. 243.

Those who take part in the endowment of research are the truest and greatest of modern philanthropists.—Professor R. H. Thurston.

COMBINATION STATIONS.

MORE than one paper has been read before the National Electric Light Association by members advocating the consolidation of electric light and railway enterprises in the same town, at least so far as the generation of electric current is concerned; and very many arguments of a convincing nature have been brought forward to show the economies which can be attained by such a pooling of interests. But, strange as it may seem, the suggestions thus thrown out seem to have been acted upon in but a very few instances. The reason for this may probably be sought for in the fact that in the discussions thus far carried on the figures given were very general and indefinite, based upon more or less assumed conditions, thus lacking the weight of arguments which are accompanied by facts and figures drawn from actual practice. This state of affairs, however, ought no longer to exist, and both electric light and railway managers will, we are certain, be deeply interested in the article from the pen of Mr. H. K. McCay, which appears in our electric railway department in this issue.

Mr. McCay shows some remarkable results in economy with combined stations for arc and incandescent lighting and railway power service; but as they are taken from actual practice no other conclusion can be derived than that there is here a legitimate field for the operation of the electrical financier,—a field almost as great as that open to him in the days of early electric lighting companies. The economy to be gained in such joint operation must in the end accrue to the benefit of the public at large as well as to the profit of the stockholders of the electrical enterprises concerned. There may be instances in which the consolidation of interests, the advantages of which are so clearly pointed out by Mr. McCay, may be impracticable, but exceptions are few, and we are certain that in a large majority of cities with companies now maintaining independent lighting and railway power stations, the joint operation of apparatus can be effected with large economy. There are to-day 400 American cities with a population over 8,000 inhabitants and below 100,000. In each of these the combination plant should prevail.

THE VITAL IMPORTANCE OF ARMATURE INSULATION.

THE complaint that the American Institute of Electrical Engineers has been rather too mathematical of late in some of its papers, and hence has damped the ardor with which members have attended the meetings, may have some element of truth in it. On the other hand, there have been several valuable practical papers lately, and none more so than that read last week on the use of micanite in armature insulation. We cannot imagine a better use for the Institute than these opportunities to discuss what promise to be very important advances in the art. If more of the commercial innovations could be thus submitted promptly to technical scrutiny and discussion on the open floor, we think the science and art would be a great gainer.

Without armature insulation, we should have no current. The armature in the dynamo is the heart of the electric distribution service of to-day, and any defect in it must react on the entire external system. How to maintain the normal, continuous working of this heart or electrical pump, if we may be allowed to carry out the analogy, is a subject which has very properly claimed the serious attention of dynamo builders from the start. Aside from mechanical considerations it was soon learned that the insulation of the armature must be maintained intact if trouble is to be avoided; and if this was observed early in the art with low tension direct current machines, how much more must it be considered a vital factor in these days of high tension alternating currents. It was well, therefore, that the subject was brought to the attention of electrical engineers. We believe it is now generally conceded that for purposes of armature insulation there is nothing which approaches mica, but its expense has thus far prohibited its use except in commutator work and in high tension alternating machines. The search for a true substitute for mica has thus far met with as little success, comparatively, as that long continued quest for a substitute for platinum in incandescent lamps. But where Nature has been chary in her supply, man's ingenuity has come to the aid of the dynamo builder by utilizing what had heretofore been a waste product. The new product, micanite, described by Mr. E. P. Thompson, appears to have all the properties of its original constituent and will no doubt prove a valuable adjunct to the materials of electrical engineering.

In this connection we would also call attention to the extremely valuable paper of Mr. T. T. P. Luquer, in which the relative insulating powers of cotton and silk, with and without shellac, are well brought out, in this issue.

ELECTRIC RAILWAY DEPARTMENT.

ON THE OPERATION OF ELECTRIC LIGHT AND RAILWAY PLANTS FROM THE SAME STATION.

BY

A. K. McCay.

At the beginning of the present year there were some half dozen electric light and railway plants owned and operated by the same corporations and from a common central station. Having had charge of one of these plants for over a year, I wish to bring to the public notice and to the notice of investors the eminent fitness and the extreme economy of operation under this system. Many railways rent their power from light companies, paying as high as $2.75 per car per day, and as low as $1.75. What I wish to show is that the cost for power in such a consolidation as above is far less than the lowest figure, and the consolidation of these interests even in small places from ten to twenty-five thousand inhabitants, may be made to pay handsome dividends to the investor. The figures I give are based on the records of these plants, and while they represent no one of the plants referred to, either in operating expenses or receipts, any one familiar with the operating expenses of a railway or light station will see they are not far wrong. We will assume the station to have average monthly receipts as follows:—

Railway, 5 cars	$2400.00
Arc lights, 125 at $8.80 per month	1100.00
Incandescent, 1300-16 c. p.	1100.00
Total monthly receipts	$4600.00

I will enumerate the expenses under four general heads. First, we will take the general expenses. This will include all expense which is common to the three branches, railway, incandescent and arc. Therefore, such expenses as coal, oil, water, labor at station, and office expenses, will all have to be summed up and apportioned to the respective business, in proportion to the amount of horse power used by that branch. After this general expense has been so divided, it is then added to the expenses which are not common to all branches; but which appertain to and are attendant on the separate branches of railway, arc and incandescent light work. It has been observed that the month of March most nearly approximates a mean for the whole year, and in my estimates below I have, as nearly as I could, taken averages for that month:—

GENERAL EXPENSES PER MONTH.

3 Engineers, $60, $60, $80	$200.00
2 Firemen	90.00
1 Cleaner	40.00
Coal	500.00
Water	30.00
Oil and waste	40.00
Repairs to engines, boilers, etc.	60.00
Office expenses including rent, ins., etc.	250.00
	$1200.00

ARC LIGHTS.

Trimmers	$100.00	
Carbons	80.00	
Arc lamp and machine repairs	70.00	
Line repairs	50.00	
		$300.00

INCANDESCENT LIGHTS.

Lamps	$75.00	
Linemen	75.00	
Repairs to line and machine	50.00	
		200.00
Total		$1700.00

RAILWAY OPERATION.

12 Conductors and motormen at $3.25	$1170.00	
Oil and waste	20.00	
Repairs	50.00	
Armature winder and two cleaners	160.00	
Superintendent	100.00	
		1500.00
Grand total expenses per month		$3200.00

The incandescent load varies from 100 to 500 amperes. Average 200 amperes for 24 hours' run.

$$\frac{200 \times 220}{746} = 55 \text{ H. P.}$$

55 x 24 =	1320 H. P. Hours.
5 cars 15 hours run at 10 h. p. apiece equal to 50 x 15 =	750 H. P. Hours.
105-1200 c. p. arc lamps for 12 hours at 100 x 12 equal to	1200 H. P. Hours.
Total H. P. Hours for Station	3270

Incandescent equal 3/8 General Expenses very nearly.
Arc " 3/8 " " " "
Railway " 1/4 " " " "

			Receipts.
Therefore Railway expense	300 + 1500 =	$1800	$2400
Incandescent,	450 + 200 =	650	1100
Arc,	450 + 300 =	750	1100
		$3200	$4600
			3200
Net receipts per month			$1400

Assuming that each car consumes an average horse power of 10, during a run of 15 hours, as has been shown above, we get 15 x 10 equal to 150 h. p. hours for one car or 750 for all five cars. The actual cost for power (being compiled from the General Expense less the net salaries) in estimate is:

$$\frac{\$950}{4} = \$237.50, \text{ as railway is } \tfrac{1}{4} \text{ of General Expense.}$$

$$\frac{\$235}{30} = \$7.85 \text{ for five cars, or } \$1.57 \text{ for one car.}$$

Assume each car operates 100 miles. Cost per mile 1.57 cents. This is low, as the cost of power given by the West End Company in their reports averages 7.65 cents per car mile. At Buffalo and elsewhere it is much less. Cost of power in South London Subway 5.20 cents. This gives a cost less than $\frac{1}{3}$ of the smallest of these figures. Now as to the incandescent lights, suppose we have 1300 connected 16-c. p. lamps. The average load we have assumed is 800 lights or 200 x 2 x 2 x24 = equals 19200 lamp hours per day or 19200 x 30 = 576,000 lamp hours per month. The total cost of this is $650. This gives $\frac{65,000}{756,000} \times 10 = \frac{650}{756}$ mills per lamp hour $\frac{86}{100} =$ of a mill.

Some time ago I had charge of one of the most economically operated and best paying incandescent stations in the country. I found then if I could get the cost per lamp hour down to four mills the profit would be large provided of course the lamps connected and the load were heavy. So we see that the combination reduces the cost of operating the incandescent lights to one-fourth.

Now let us look at the arc lights. 125 arc lights, 1,200 c. p., take very nearly 100 h. p. at 12 hours average, equal 1,200 h. p. hours or 125 x 12 = 1,500 lamp hours. 1,500 lamp hours x 30 equal 45,000 lamp hours per month. Total cost $750 or $\frac{75}{45} = \frac{15}{9} = 1\frac{2}{3}$ cents per lamp hour. This is also an extremely low figure for the arc lamps.

It may be said that I have assumed too low an estimate of expenses, but I have the actual figures at my hand, and I am at least 15 per cent. above the true expenses of the companies referred to. Suppose now we look at the original cost of such a plant as I have indicated above. We will take a railroad five miles in length with five cars and everything in place to cost somewhere near $75,000.

Incandescent station and pole line; station large enough for all and capacity of 3,000 16-c. p. lamps	$70,000
Arc light plant,	30,000
	$175,000
	06 per ct.
	$10,500
Net revenue as shown from actual practical experience to be	$14,500
Year's surplus,	$4,000

This is only given as an example. If the management is pushing, active, and energetic, the net revenue should be very easily $20,000 per year. The business would gain year by year, the cost per car mile would be reduced; the cost per lamp hour both for arc and incandescent service would reduce, and, in my opinion, based on actual experience and from knowledge of what other plants are doing, this combination of interests is one of the most profitable that can be made. It is the next thing to come in commercial electrical development.

LIGHTNING ARRESTERS FOR STREET RAILWAY CIRCUITS.

BY

William A. Turbayne

There seems to be an erroneous idea among some manufacturers of lightning arresters as to the form of arrester best suited for the protection of street railway motors and apparatus. It is well known that the most suitable form for such work would be that in which electromagnets or solenoids are entirely eliminated, on account of the high resistance offered to the lightning discharge, and the impedance is certainly high when magnetic coils are used in the discharge circuit, whether they contain an iron core or not; the iron core, of course, serves to intensify the effect, although the self-induction in the convolutions themselves is enough to render the arrester unreliable.

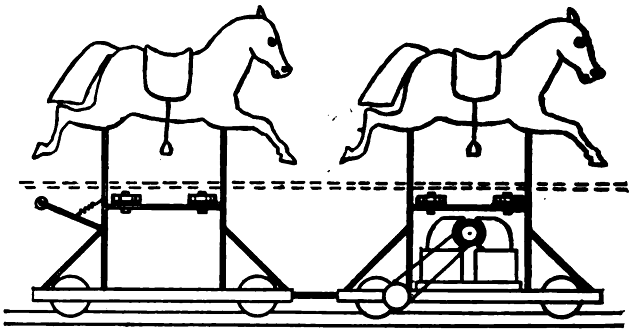
Were the insulation on the field magnet and armature cores sufficient to withstand the excessively high tension static discharge, then the above described arrester might prove effective, as offering the only practicable path to ground; but as such is not the case, then the only other paths to earth would be through the motor windings; but on account of their exceedingly high reactive effect, the discharge must necessarily break through some weak point, in all probability between the armature windings and core, and force its way to earth through the framework, at the probable expense of the armature.

It is thus evident that a great deal depends upon the arrester for the protection of the apparatus and great care should be bestowed thereon. If electromagnets were used in their construction it would be advisable to place a non-inductive resistance or a pair of discharge points, as a shunt to the magnet coils, the static discharge preferably taking that path, although the following dynamic current would flow through the low resistance magnet and perform its proper function. In a lightning arrester designed by the writer some two years ago, a succession of fuses were automatically placed in circuit as the one previous melted and several good forms working on the above principle are now on the market, as well as many other efficient and novel forms. But to place in the discharge circuit of an electric railway system an arrester containing a pure and simple electromagnet or solenoid, without even a non-inductive shunt, would surely seem to be an unpardonable sin, and one which would undoubtedly have been punishable by death if committed during the existence of the strict laws of the Medes and Persians.

AN ELECTRIC RACE-TRACK.

BY L. M. PINOLET.

At Sohmer Park, an out-door amusement resort in the city of Montreal, an electric race-track, suggested by the one at the Frankfort Electrical Exhibition of 1891, has been constructed according to plans furnished by the inventor, Mr. A. Sallé, of Paris. It consists of an oval wooden platform about 150 feet long by 100 feet wide and 4 feet above the ground. Extending around the platform is an oval track, some 30 feet in width, divided into eight parallel courses upon each of which are two large hobby-horses coupled together, one close behind the other. These horses are propelled by electric motors around the track along their particular courses, the movements and speed of each pair being under the control of an operator stationed in a small building at one side of the track. Each pair of horses—moving independently of its neighbors—seems to be taking part in a real trial of speed. At one moment a certain pair is ahead, then another takes the lead, who may in turn be passed by some other horse, and so on, thus affording the excitement and amusement of an actual race to both riders and spectators. The horses are mounted upon trucks, which are under the platform, by means of two upright iron bars fastened and braced to the front and rear ends of each truck. The truck consists of an oblong iron frame provided with two wheels, one before the other, as in a bicycle. These wheels have double flanges to permit them to run on a circular or oval single-rail track laid upon the ground beneath the platform. There are eight of these tracks, corresponding to the eight parallel courses, extending around the platform about three feet apart and equidistant from one another, over each of which is a continuous slot in the platform for the upright bars to pass through. To the lower side of the platform are attached square wooden beams placed end to end so as to form continuous rows on both sides of every slot. These rows are parallel to the slots at a distance of 4 or 5 inches from them. At such a height as to be a little below the platform, the upright bars of each truck are connected by a horizontal iron bar, at opposite ends of which are two iron wheels whose axles are vertical and supported by studs on the bar. These wheels are of such a diameter as to fit loosely between the rows of beams, which serve as guides to keep the horses in an upright position, and prevent the upright bars from coming in contact with the edges of the slots.



An Electric Race-Track.

Upon each circular track there are two trucks coupled together. Upon the foremost of each pair is an ordinary 2½ h. p. series electric motor, which drives one of the truck-wheels by means of a single reduction gearing connected with its pulley by a belt. Current is conveyed to the motors by copper wires fastened to the lower side of the platform, contact being made by an ordinary trolley-wheel, mounted on a short arm, and the rails are used for the return. A 100-volt shunt-wound generator supplies the current.

The speed of any individual motor is independently controlled by a rheostat in its particular circuit, by means of which it can also be started or stopped. In addition, the speed of all the motors in a body is regulated by varying the current supplied to them from the dynamo by means of a rheostat in its field circuit. The switches, rheostats and other apparatus are located in the operator's house. The speed of the motors is regulated so that the horses move at a rate of about nine miles per hour which has been found to be the most suitable speed.

The trolleys are placed on the rear trucks, so that in case a coupling between two trucks should break, the supply of current to the motor would be cut off and both trucks would stop, thus avoiding the possibility of one truck continuing its course alone around the track till it overtook and collided with the other.

This plant was manufactured and installed by the Royal Electric Company of Montreal, under the superintendence of Mr. Lewis Burran, of that company, to whom the credit is due of important modifications which materially improved the working of the apparatus.

MISCELLANEOUS.

THE USE OF 500-VOLT MOTORS.

We are glad to say that the subject of 500-volt motors, lately discussed in these columns continues to attract attention. We are in receipt of further communications of interest on this point. Mr. A. D. Newton, of the Eddy Electric Manufacturing Company writes us: "The advantage of 500-volts for power circuits has been appreciated by a great many power companies and we are selling a great many motors for use on those circuits. We give you here a list of some of the cities that we are dealing with for this voltage. Boston, Lowell, Utica, Newark, N. J., Pittsburgh, Cincinnati, Chattanooga, New Orleans, St. Joseph, Omaha, St. Paul, Chicago, Portland, Ore., Atlanta, Waterbury, Conn., Providence, Buffalo, Quincy, Ill, Burlington, Ia."

Mr. C. Kammeyer, of the Jenney Electric Motor Company of Indianapolis writes: "Regarding 500-volt motors we can say that we find the use of such motors increasing steadily, nearly half of our inquiries and orders being for generators and motors of that voltage. We never could see any good reason why 500-volt apparatus should not be used more extensively than it has been in the past. With improved methods of manufacture and a past experience as regards insulation, etc., their operation should now give little or no trouble, and the advantages over the use of machines of lower tension are enormous. We hope to see the day when direct current apparatus of even 1,000-volts pressure will be as much in use and demand as 110 or 220-volt apparatus is now."

Mr. J. W. Wilshire, president and treasurer of the Card Electric Motor & Dynamo Company of Cincinnati, O., says: "We have been building our motors very successfully for 500-volt circuit, for the past year or more, and have now in use, in this city and near vicinity about 235 motors for 500-volt circuit, aggregating about 925 h. p., and in every case where these high voltage motors are in use, they have given splendid satisfaction. We have not had the slightest trouble with one single machine that we have installed. In fact we find that the best circuit for commercial use in regular power work, is the high voltage constant potential circuit, and nearly all that we are installing now are on either the 220 or 500-volt circuit."

Mr. F. A. Scheffler, superintendent of the Brush Electric Company, Cleveland writes us: "In regard to 500-volt motors for light and power circuits, we would state that we can only agree most heartily with you in your views in reference to such a system, and would add that we are making quite a number of 500-volt motors to run on constant potential circuit. We have also made a quite a number of motors and generators to operate upon 1,000-volt circuits, some of the latter being used at the Calumet & Hecla mines, where we have five 75 h. p., such motors operating in the mines, at varying depths, underground, from 800 to 4,800 feet.

"At Montgomery, Al., we are putting in a large plant for arc lighting and alternating incandescence system; also a 500-volt power circuit system, with generator, switchboard and some motors to run from this circuit.

"This, we feel, is only the beginning of what will grow into an extensive business, especially, where parties have extra power to spare, or where water power can be had in large quantities and at small expense."

TRANSFORMER TESTS.[1]

Dr. Fleming's paper on "Experimental Researches on Alternating Current Transformers," read before the Institution of Electrical Engineers on the 24th ult., is a monument of painstaking experimenting. It will occupy about a hundred pages of the Journal of the Institution, and bristles with data of tests of different transformers. Dr. Fleming's results are generally beyond any suspicion of inaccuracy, and the enormous labor involved has been well spent as it definitely settles several important points. In the first place it explodes the fallacy that the iron losses are reduced at full load. Of course, the loss goes down to a minute extent because the induction is slightly less, but it was thought in many quarters that it went down to a very small fraction of its "no-load" value. This fallacy was due to the use of complicated and inaccurate methods of measurement, and never had any real vitality, so we shall probably hear no more of it. This point had also been made quite clear by Messrs. Ayrton & Sumpner in the meantime, and Dr. Hopkinson and his son had also made tests of a Westinghouse transformer. Dr. Sumpner had devised a special method of testing to get accurate results at full load. Another point Dr. Fleming has settled is that the wattmeter is perfectly accurate. Mr. Swinburne has advocated the use of the wattmeter for the last five years, and has been generally ridiculed on this point. He would now be able to laugh at his opponents if his firm had not provided Dr. Fleming with a wattmeter which was inaccurate, and has subsequently been replaced. It is, however, a considerable relief for those who did not know it before, to realize that the efficiency of a transformer can be found in a few minutes, by means of a single instrument, and that three voltmeters, three ampere-meters, split dynamometer, and calorimeter methods are all unnecessary complication.

The next point to determine was whether the open or the closed circuit was the better. Dr. Fleming has certainly shown with unassailable accuracy that the "Hedgehog" transformer sent him had nowhere near the efficiency claimed for it by its inventor. Why a transformer with so little copper loss and so little iron should absorb so much power in proportion it is a little difficult to explain. There will, no doubt, be an interesting discussion on this paper.

AN INSURANCE MEETING ON THE PACIFIC SLOPE.

A conference committee meeting, consisting of a special committee of the San Francisco Chapter of the American Institute of Architects, of the California Electrical Society, with Geo. P. Low, as representative of the Pacific Insurance Union, was held in the rooms of the Fire Underwriters' Association of the Pacific, San Francisco, on the evening of Nov. 23, for the purpose of discussing the subject-matter of a paper prepared by Mr. Low for the October meeting of the Underwriters' Association, on "Electrical Impostors" and of devising means by which the ideas contained therein may be enforced. The organization of the meeting was effected through the election of Mr. Low as chairman, with H. T. Bestor, editor of the *California Architect*, as secretary. As the result of the deliberations, a resolution was adopted requesting the committee of the California Electrical Society to prepare a general set of specifications under which accessible wiring may be placed, and also to prepare a second set of specifications under which the wiring at present countenanced by safety requirements, and which is considered safe if properly inspected, may be placed. These specifications, when drafted, are to be submitted to the architects for consideration and revision, when they will be again returned to the conference meeting and formally adopted. It was the sense of the majority of the meeting that it would be inadvisable to endeavor to effect a radical change in existing methods of electrical construction, especially so in localities under the surveillance of an electrical inspector. Hence, the resolution proposes to countenance ordinary methods of wiring, as defined by existing insurance requirements, in any instance where same can be inspected by some electrician in good standing. This will necessitate the organization of an electrical exchange on the Pacific coast similar in its nature to the New England Electrical exchange. The meeting adjourned subject to the call of the chair.

MICANITE AND ITS APPLICATION TO ARMATURE INSULATION.[1]

BY EDWARD P. THOMPSON, M. E., FOR CHARLES W. JEFFERSON AND ARTHUR H. S. DYER.

An armature and its commutator consists of the combination of two elements, namely, electric and magnetic conductors and insulators. In the earlier days of armatures, the electrical and mechanical dimensions and proportions of the conductors were considered of prime importance. The first armatures were small and the electromotive force low, and consequently little attention, comparatively, was given to the element, insulation. Lately, simply paper, cloth, convolutions of ligatures, or these materials impregnated with shellac or similar insulating varnish or paint were employed for the purpose of preventing leakage or short circuit. To remove the solvent of the shellac, the armatures were baked for twenty-four hours. Judging from the variety of materials used at present, and the changes from one material to another, it would seem that the insulators are now receiving their share of consideration, while the core, wires, commutator sections and other conducting portions are secondary details. Why so much difficulty with armature insulators and so little with other insulators, such as line insulators? Because, in the former, not only must the material be of extremely high resistance, but also unaltered under the effects of heat and must be crowded into very small quarters. Space must be economized. If the electric current or heat alone were present, and if space were not so much limited, the problem would be easily solved. It yet remains to be proved that any known substance is absolutely a non-conductor

—nor is the resistance of a given conductor constant. Unfortunately for the armature constructor, the worse the conductor the less the resistance with increase of temperature. An extra current is produced in metals upon variations of current. A diminishing of current occurs when first entering a substance of high resistance. Finally and gradually the current becomes constant. This action for convenience is often called polarization. As this property is noticeable only in long lengths of the insulating material, it has little bearing upon any of the armature elements other than in connection with the covering of the wires. The substance possessing the property of polarization in a marked degree is gutta-percha.

Paper or fabrics by themselves, should never be used as an insulator, because when moist they conduct a current so well that they may properly be termed semi-conductors. A coating of shellac or oil upon almost any substance enormously increases its resistance, and protects porous and deliquescent substances from water. Paper thus covered serves, with machines of low electromotive force, the purpose of preventing leakage, but, by no means, perfectly in practice with large machines. Its advantages are more in the nature of convenience and cheapness than of efficiency.

Paper which has been thoroughly dried is of very much higher resistance—so high that it falls under the head of non-conductors, and therefore, the shellacs should not be applied until after the paper has been subjected to a thorough drying process.

It is a peculiar property that a given substance in a compact condition is of very marked higher resistance than when powdered or comminuted; for example, pulverized glass is a semi-conductor, while sheet glass is as high in resistance as silk. This property has been noticeable in armature practice. If the insulating material is cracked here and there, it is unfit for armature use. The cracks are in the nature of interstices between the particles of a powder, and at the cracks the material is in part ground. The explanation may lie in the distinction that the pulverized material has more surface, or that damp air exists in the spaces between the particles, or that a spark can traverse a gas better than a solid, or that each particle becomes coated with a film of moisture. The last seems the most probable, because the best surface concentrators of water usually exhibit the property most strongly.

The locations of insulation in an armature are between the armature disks to prevent eddy and Foucault currents; between the core and the windings to prevent the current from short-circuiting the coils through the core and burning out the armature; between the commutator sections to prevent leakage from one coil to another; over projections or in grooves in the core; and around the wire to guide the current in convolutions. All these parts, even in the best made armatures become more or less abnormally hot. Means have been planned and sometimes put into practice for cooling the parts, and thereby saving the insulation. One method consists in constructing the armature after the style of a fan or with large radiating surface; another, in equipping a device to blow out the sparks at the commutator, and again, in using cooling insulating liquids. With whatever precautionary means the machine is equipped, the parts, either accidentally or through inefficiency of means, will become abnormally hot. The machine will be injured if combustible materials form the bulk of the insulator. The materials of an ideal armature consist of copper, iron and a heat-proof and waterproof non-conductor. If the material is combustible, or altered in its chemical nature, by heat, its resistance is changed and generally lowered. Manufacturers of incandescent lamp filaments know that complete carbonization cannot take place except at a very high temperature, like 3,000 degrees Farenheit. An armature may rise to 500 degrees. At this temperature, easily carbonizable materials, such as linen, cotton and other forms of cellulose are weakened, blackened and the resistance reduced. Shellac, although blackened at this temperature, is converted into those compounds whose resistance is not lowered. Shellac forms an exception, therefore, in being charred by such a temperature without reduction of resistance.

There is a greater detriment than chemical change by heat. The material cracks, becomes somewhat comminuted, and the resistances, both mechanical and electrical, are therefore greatly reduced. If paper or cloth, or even shellac is depended upon as the insulating material rather than as the binding material, it is not electric proof, because principally, it becomes, when charred, fractured at numerous points, if not completely pulverized. As to why shellac is not appreciably lowered in resistance by partial carbonization may be because it is an animal substance.

One of the most important attributes of an armature should be its rigidity. It should be like a rock in this particular. If the insulation should consist of a soluble material, for example, and the same dissolved out after the completion of the armature, or of some material that would be reduced in size by heat, then the wire and bolts would soon become loose from the rapid rotation and vibration, and finally the armature would be useless. Change in volume of the insulators has caused nine-tenths of the armature break-downs.

In the matter of insulation between the disks it was found that oxidized or rusted laminated armature disks would insulate without any addition of paper or similar insulating films. The only difficulty with such a construction is one of degree. Iron rust insulates, and it is heat-proof; but it does not insulate sufficiently to compensate in most instances for its simplicity and cheapness, and besides it is not applicable to any other part of the armature than between the laminæ of the core. The great advantage lies in the extreme thinness of the oxide coating, whereby a large amount of iron is obtained in the core. A modification has been suggested, which consists in placing thin mica sheets between every half-dozen of the disks. Again, iron wire, or ribbon rusted has been employed for armature cores. The wire or ribbon is formed into a ring, around which is the electric conductor. Another modification consists in "case-hardening" the iron, and also in japanning the surface. As to commutator insulation, natural mica sheets have been almost universally employed.

If it were not for the matter of mechanical construction and heat, shellaced glass would make a good armature insulator. It could be molded into any form and made of any degree of thinness. Its objections, however, are well known. Very gradually, and more so than would be conjectured, mica made its appearance in armatures. The introduction of mica into practice appears to have been brought about in the following manner:—An accident would happen to an armature, and before the next night it must needs be repaired. In order to make the temporary remedy, mica sheets or bars would be interposed. In the case of subsequent accidents, the portion repaired by mica, was the last to yield. Therefore it was proposed to build the armature primarily with mica. But this change took place very, very gradually, but surely. Manufacturers of stoves, the leading houses being also importers of mica, soon experienced a growth in the mica department of their business, until at present some import more for the electrical industry, especially for armature use, than for stoves. Why it was not employed from the first, no one could positively assert, otherwise than to guess that no one probably thought of it, or insulation was not considered of much comparative importance, or cheapness of material in construction was allowed to counterbalance efficiency of action and durability.

Of all substances, mica probably is the best material for use in armatures, if it is desired to obtain not only efficient electric insulation, but also durability under the influence of heat. The highest temperature to which an armature is subjected, even by short circuit or bad construction, will have no injurious effect upon mica. Mica, thick or thin, may be held in a gas flame without cracking, burning or melting. It remains unaffected. The reason of this is better understood when it is remembered that it consists of aluminic silicate, containing also potassic, sodic and lithic silicates, and some ferrous and ferric and manganic oxides. Its chemical constitution varies.

One quality of mica is that which is commercially termed amber mica, and is usually mined in Canada. It is so named from its appearance and not because it is amber or in any other way similiar to it than in its color. India mica is a commercial form noted for its uniform cleavage, great thinness of its laminæ, flexibility without fracture, and its resistance, which is much higher than that of amber. Carolina mica is another variety. It is obtained in sheets in the western part of North Carolina. It is the best mica for stoves, but it is too hard for some electrical purposes. Mica occurs in so many specific forms that particular names have been given to it. Muscovite is one of the most common varieties. It occurs in different colors, namely, a dark green, yellow, brown, white and gray.

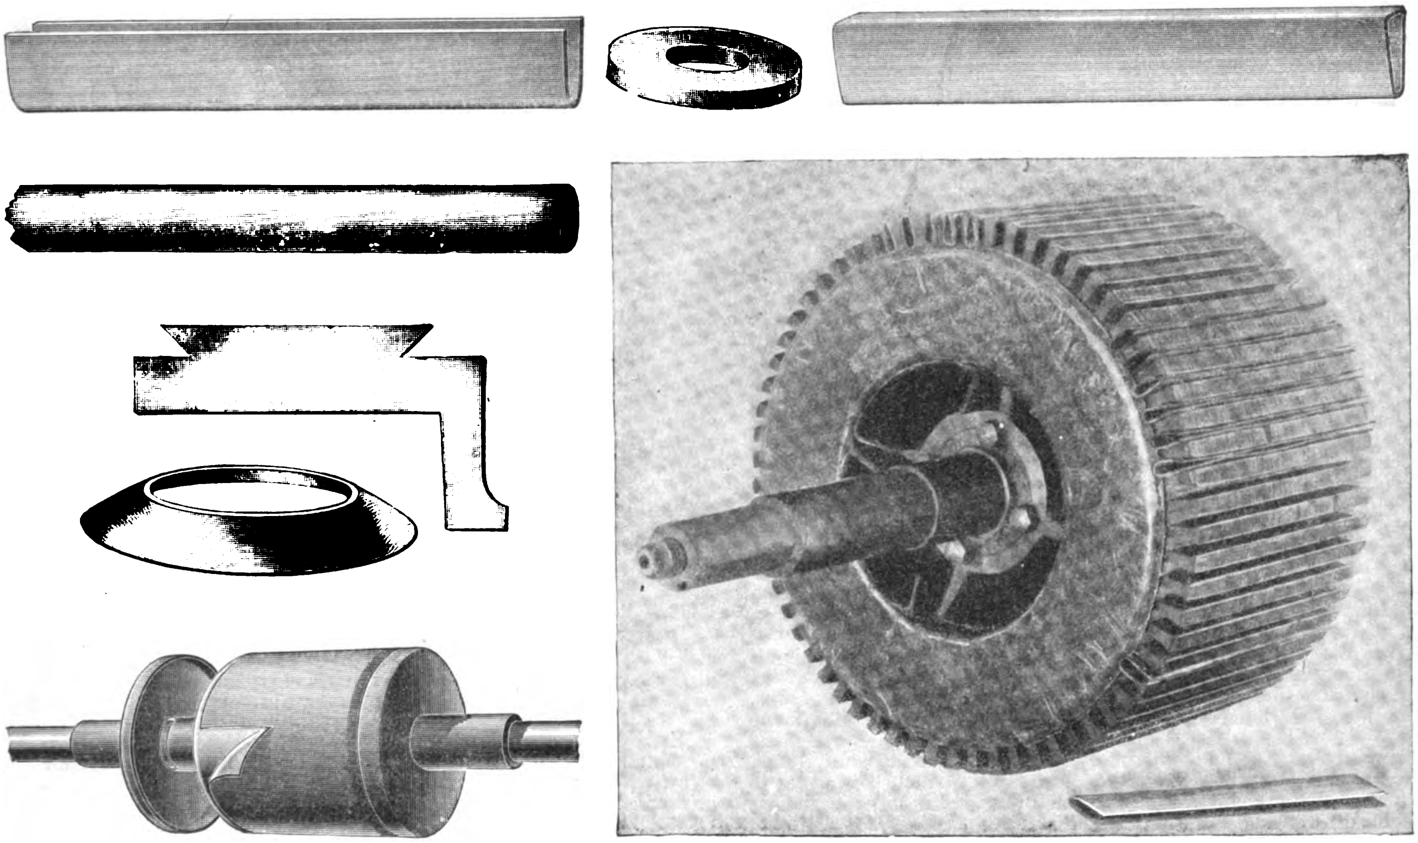
The insulating power of mica is superior to that of any other substance applicable to armatures. An advantage, peculiar to itself, is its even, laminated structure. How wonderful is the thinness of its individual layers! A piece of ordinary writing paper is about .005 inch. Mica layers have been obtained of a thinness of .00003 inch. Mechanical difficulties prevent its being split thinner. By pasting it upon a hard surface and splitting it off as much as possible, the remaining fragments are so thin as to become beautifully irridescent. The builder of armatures can therefore split the sheets into any desired and uniform thickness with great ease and accuracy. An interesting property of mica and one not generally recognized, is its homogeneity of structure and clear transparency, although so black when thick. The writer used a piece one-quarter of an inch thick for observing the recent solar eclipse. The effect was better than with smoked glass and as efficient as black glass much thicker.

A valuable property of mica in connection with commutator insulation is its proper degree of hardness, whereby it does not wear away too rapidly under the action of the brushes. If rubber were used, for example, even if it did not burn, yet it would wear off and sparking result, because the commutator surface would not be truly cylindrical. The brushes would be set into vibration. Again, mica is capable of the finest pulverization, so that any wearing which does take place does not result in the liberation of gritty particles, which would also cause sparking. Such mishaps occur with hardened artificial plastic insulators. The insulation should be just so thick that the current cannot jump across from one section to the other.

Although so superior for armature insulation, mica is, in its natural structure, accompanied by certain objections, which, in trying to overcome, were more serious than had been anticipated, as it was not until after a long series of trials that a successful article was produced, and not until a novel apparatus for cheapening the process of manufacture was devised. The apparatus is now in operation on a large scale. The description at present is confined, however, to the article, and to full information of its structure, manner of using and properties.

The objections alluded to are: Mica, as found in nature, occurs in flat sheets only. It has a high degree of elasticity, so that when once bent and released it assumes its original form. If folded, its brittleness causes fracture. If the natural sheets are compressed in a mold, to try to form armature insulator heads, for instance, it is completely broken up.

Secondly. Natural mica sheets correspond financially to plate glass. The larger the sheet, the higher the cost per square inch. Mica in small pieces, from four to six square inches, is exceedingly abundant and very cheap. It is often called waste mica, because very limited in its uses, and consisting often of trimmings from larger and more useful sheets. In medium and large sizes of armature, the naturally built up mica is so expensive as to be objectionable, although not so much so as to entirely prevent its employment.



Specimens of Micanite Armature Insulation.

Thirdly. Between the hundreds, nay, thousands, of thin layers damp air can enter, and also water, accidentally, which cannot easily or effectually be removed.

Fourthly. Mica splits so easily that handling causes injury.

Fifthly. Mica cannot be cut transversely to advantage. The edges are unworkmanlike, being ragged and jagged. Neatness in drilling, sawing and turning is difficult.

Among the attempts which have been made to overcome these objections are those involving the use of pulverized or comminuted mica, which is mixed with a liquid cement and stirred into a paste. While still soft, the mixture is rolled or compressed into any desired form, as if consisting of so much plaster-of-paris. In order to give it sufficient strength, one-third of the product is cement. The mica sparkles here and there on the surface, as it glitters on granite. This article should be called a cement insulator, and not a mica insulator, because the current can flow in a straight circuit through the plate without encountering any mica. The cement forms numerous rectilinear paths for the current independently of the mica, and therefore the product in no sense is an equivalent of mica.

A modification of this type of insulator consists of a coarse and thick textile fabric, whose pores and meshes are filled with a mixture composed of comminuted mica and a suitable adhesive substance. Another consists of finely divided asbestos mixed with pulverized mica, silicate of soda and sulphur compounds. It is molded by pressure into any desired form.

The comminuted mica-cement type is useful in trolley wire supports and similar insulators, but for dynamos it is useless, not only for the reason stated, but because of its softening and running under slight heat, being so necessarily rich in cement. If the cement is that kind that chars, the mica crumbles apart. Mineral powders have been mixed with it to render it more fireproof.

An example of the manner of using non-comminuted mica between the core and the windings consists in covering the core with paper, laying sheets of mica over the paper, then laying on another sheet of paper, fastening the whole together by convolutions of cords or similar ligatures, and finally applying the coils. During operation the paper and mica may shift from their positions, and thereby affect the rigidity of the armature as a whole. Again, the process of applying the pieces, and keeping them temporarily in position, requires repeated efforts and results in a display of crude workmanship.

The exhibits before you show practical results of work carried on for the purpose of overcoming the objections named.

Large Plates.—One of these plates is a yard square and .035 inch thick. Another is of the same size and 1 inch thick, and another about 4 inches by 12 inches and 1 inch thick. They have nothing to do directly with the armature; but could serve as foundation plates for a dynamo or motor. They are practically all mica. A *natural* plate of mica of the larger size would be a curiosity—a rarity. Any of the sheets may be cut up into any desired size and shape. The layers cling together much more tenaciously than in the natural plate. The path of least resistance from one side of the plate to the other is in a straight line, and a straight line intersects numerous mica sheets, and, therefore, the article is a mica insulator and not a cement insulator. These plates are made by such steps and apparatus that when subjected to heat in the armature, no injury whatever is produced.

Further, they are superior to a sheet of mica as it comes from the quarry, in that they do not absorb water or damp air; in that they are stronger to resist either pressure or tension; in that they may be neatly and easily sawed and drilled; in that they are enormously less costly; and in that they are of about the same resistance. By picking the exhibit apart, you can easily learn the structure. The mica of which it is composed is non-comminuted, but the pieces are exceedingly thin. The thickness is, by measurement, about .001 inch, *i. e.*, about as thin as tissue paper. The sizes vary from 2 to 6 or 8 square inches. In each layer of mica, you may notice that the sheets overlap at their edges, and the cement between the layers is hardly noticeable. The former mentioned plate weighs about four lbs., and the latter over 100 lbs. It is a convenient quality in connection with mica that it can be split into pieces of the thickness required for the particular device under the process of construction. This property is also possessed by the plates exhibited. A thin and long knife may be caused to force its way in any of the many planes parallel to the surface, for the purpose of reducing the thickness or obtaining several thinner sheets from one thick plate.

Some tests were carried on to determine the relative values of these plates, and plates of comminuted mica and cement. Using the words of the electrician who originated and performed the tests, he says: "For the purpose of insulating armatures, any solid insulating material should possess considerable strength and should maintain its strength when submitted to a moderate degree of heat. One piece tested consists of ground mica and shellac, mixed together and rolled or pressed between plates to a uniform thickness. In order to test it, I placed it upon a steam-table and left it for a minute, at the end of which period I tested its strength by pressing the end of a piece of wire against its surface with very light pressure. The end of the wire, which was blunt and made of copper, easily pushed its way through the sheet and left a hole when removed. In removing the sheet from the steam-table it warped. The second plate consists of layers of sheets of mica, cemented together with overlapping joints. This sheet I placed on the same steam-table used for the other sheet, and after one minute had elapsed, tried to thrust the same piece of copper wire through the plate, but without success, though exerting all the strength that could be brought to bear upon it by my hand. After the sheet had been on the steam-table for five minutes, I placed it on a thick iron plate, laid a piece of the same copper wire upon its upper surface, put a second sheet of wrought-iron on top of it, and put the whole into a hydraulic press. It was then submitted to a pressure of 2,000 lbs. per square inch for one minute, and the result was the flattening of the wire and a very slight crumpling of the mica sheet on the opposite side. The plate was then placed between two copper plates, and a weight of about four lbs. placed on the upper plate. The insulation resistance of the plate was then tested and found to be 25,500 megohms. I have used similar plates, similiarly prepared, in motors, upon which a load of 50 h. p has been placed, the entire thrust of the motor being received by the plates, which in this case were less than one-sixteenth of an inch thick. The temperature was brought up to 650 degrees Fahrenheit, sufficient to burn cotton and melt hard solder, without injuring the insulation."

Curved Specimens.—Similar remarks substantially, may be made about these, as about the large plates. Natural mica plates could never be given a permanent set, or molded into curved forms. The armature head consists essentially of an annular disc, provided with flanges around one or both peripheries. It is in one sense a continuous piece. The flanges, you may notice, are made separably and then fastened to the discs. There are no joints. Some of the peculiarly curved forms are furnished in order to illustrate that the article may be manufactured in any imaginable form of uniform structure, and in single pieces of uniform properties throughout.

Tubes.—In order to show the unlimited forms into which the material may be molded, a tube several feet long is exhibited. It may be cut up for use in certain types of armature, or when long, for use on board ship, and in general interior conduit installations.

Stamped Forms.—The flat pieces of peculiar form could be made from the beginning in individual pieces, but it is much cheaper, if stamped from larger plates. Before using the large plates for any purpose where an exact thickness is required, they are burnished or surfaced off by machinery. Some of the plates before you are in the crude state, and little scales here and there can be peeled off. The others are so different as to resemble a metallic surface, and when struck ring like metal. Some of the forms are for large commutators. Others are flat rings for field-magnet cores. The very irregular flat pieces are for certain types of commutators. On account of the almost metallic qualities the product can appropriately be termed an "insulating metal." For convenience, it is called micanite.

Commutators.—In equipping a commutator with this material, it is necessary to know something which has been learned by early users, only through experience. The insulating and metal sections are put together in the usual manner, and the whole is heated to a temperature higher than that which it will reach in actual practice. While still hot, the elements are clamped tightly together.

Among the exhibits, is a mass of odd pieces of mica sometimes called waste mica; also you will find similar pieces split as fine as possible. These are the results of the first operation. The next step consists in putting them together in the manner shown in the exhibits, that is, in layers with overlapping edges. Between them are layers of a cement having those qualities which fit the product for the purpose intended. Until only recently, these pieces were always laid on by hand. Their manufacture required one factory girl per cubic foot per hour. Now, one girl can do the work which formerly required twenty. The girl feeds the machine, and it does the rest. The amount of cement employed is practically infinitesmal, because while in a plastic condition, the mass is subjected to such a pressure that a mere trace remains, and yet sufficient to obtain proper adhesive qualities. From the beginning to the present, improved processes and new machinery have been required.

I will close this paper by presenting certain topics which appear to be suitable for discussion, but which need not be adhered to.

SUGGESTIVE TOPICS.

Armature.—Rigidity and its dependence upon insulating material employed. What has been learned by observation and special tests?

Preservation of Insulation.—Is it better to try to remove the cause of heating, or to neutralize the heat?

Burning Out Armatures.—What does insulation have to do with it, and what are the remedies? Also, what are the causes?

Durability of Insulation.—Differences in connection with armatures for inside use, such as installations and outside, *i. e.*, railway, mining and elevator use. Effects of atmosphere, motion and rough treatment.

Financial.—Does the expense of insulation, if the best, have an appreciable effect upon the cost of construction, and, on the other hand, will it pay in the end to put in a cheaper material?

Comparative Merits of Insulating Materials for Different Conditions.—Effects of high potential. Power to resist spark puncturing. What have tests shown as to properties of materials to withstand "break-downs," independently of high ohmic resistance?

Dr. James Bowstead Williams has carried on a long series of tests upon the comparative specific resistance of mica and micanite. The data and results are as follows:

The conditions of the tests were absolutely the same in all cases. The potential was constant, being over 3,000 volts. A dynamometer served to accomplish the same pressure for different materials. All the samples were kept at the same temperature and under the same hygroscopic conditions for several days. Samples were of uniform thickness. The best samples of micanite gave approximately the same reading as the best India mica, indicating that the resistance of micanite is equal to that of the best commercial mica.

RULES RELATING TO ELECTRIC LIGHTING AND POWER SERVICE AT THE WORLD'S FAIR.—II.

RULES GOVERNING LIGHT AND POWER IN ELECTRICITY BUILDING TO BE SUPPLIED BY THE WORLD'S COLUMBIAN EXPOSITION.

Exhibitors in the Electricity Building will be divided into two classes: First, those who contribute to the service of lighting and electric power transmission for the building; second, those who do not so contribute.

Contributors will be again divided into two classes:

(1) Those who furnish generators connected to prime movers in machinery hall.

(2) Those who contribute to the service lighting of electricity building through motor power taken from circuits in the electricity building.

Contributors to either class will be required to enter into a formal contract with the director-general, to be approved by the director of works, for furnishing and operating machinery offered in accordance with the following general terms:

No steam power being available in the electricity building, all generators provided by contributors of class (1) must be installed in machinery hall. Generators provided by American companies will be located in the regular service plant in machinery hall. Generators provided by foreign companies will be located in the spaces severally allotted to these countries in machinery hall.

Power circuits will be led from the generators of each contributor of class (1) through existing subways from machinery hall to the electricity building. The several exhibitors offering generators for this service are expected to furnish and visit all at their own expense the several power circuits before mentioned, subject to the supervision of the chief of department of electricity.

The aisles of the electricity building will be illuminated by arc lights, which will be considered the service lighting for the building. Arc lights, in addition to these, as well as all incandescent lights, and power for keeping exhibits in motion, will be considered as special service rendered to individual exhibitors.

Power for operating generators needed for the service lighting will be furnished free of cost to the exhibitors installing this light. In consideration of such contribution to the service lighting of electricity building, exhibitors participating in this service will be granted such amount of extra power and light for the operation of their own exhibits as may be mutually agreed upon between them and the director-general.

Arc and incandescent lights may be taken direct from the several power circuits leading from machinery hall, or they may be furnished from generators driven by motors taking current from the power circuits before mentioned, motors and generators in this latter case being located in the electricity building. Arc lights for all night service are an exception to this rule, and will be supplied from the regular service plant already contracted for by the World's Columbian Exposition.

Contributors of class (2) who use current from the power circuits will be expected to provide the necessary motors, generators, and shaft free of cost to the World's Columbian Exposition. Exhibitors contributing to the arc lighting necessary in the service of the building will be expected to wire, hang and maintain such lamps as may be assigned to them free of cost to the World's Columbian Exposition. Such arc lamps, incandescent lights and motors as may be installed within the contributing exhibitors's space will be wired and hung by said exhibitor at his own expense.

In order to provide for lighting and power service to those exhibitors who do not contribute to the service of electricity building, it is proposed to assign to each exhibitor contributing to said service a specified portion of the electricity building in which to furnish special lighting and power. All works of wiring, hanging and maintenance of lamps, etc., done for other exhibitors in such space will be paid by the World's Columbian Exposition at the following rates:

(1) For each incandescent lamp, including the first lamp and socket with installation on a plain cord or pendant, $3.50 per 16 candle power lamp.

(a) Special fancy wiring will be furnished at an extra cost to be paid by consumer under special agreement with the director-general, approved by the director of works.

(b) Fixtures and shades will be furnished and maintained by consumer.

(c) Lamps of other capacities, fancy or colored lamps, will be furnished in accordance with special agreement with the director-general, approved by the director of works. Lamp renewals must be furnished free of charge by contributor. Breakages must be purchased by the consumer from the exhibitor supplying his exhibit, at the usual market price.

(2) For each arc lamp, including ceiling block, suspension rod and lamp complete, $35. Lamps must be furnished with opal globes. All care and attendance to lamps and circuits must be furnished without extra charge by the contributor maintaining the circuit.

(3) All wiring necessary for the installation of motors within the space assigned to each contributor shall be done by said contributor at the expense of exhibitor desiring said power, at the following rates:

One-half horse power and less, $8.00.

One to five horse power, per horse power, $5.00.

More than five horse power and not exceeding ten horse power, per horse power, $10.00.

More than ten horse power, per horse power, $8.00.

Fractions of a horse power will not be considered except for motors of less than one horse power. In all cases the rating of the motor will be the standard rating of the manufacturer.

Service connections, as well as all lamps and sockets, installed at contributor's expense, shall be maintained and owned by said contributor. All alterations of original installation shall be made by said contributor after written agreement between the exhibitor desiring change and the director-general, approved by the director of works.

All installation and operation shall be subject to the inspection and approval of the chief of the department of electricity. Installation must conform to the national code of the Board of Underwriters, subject to the inspection and approval of the director-general.

Service will be provided only from May 1 to November 1, 1893, and during exposition hours, except by special authority from the director-general and director of works.

The service rendered will be entirely at the risk of the consumer. The World's Columbian Exposition will not be responsible for stoppages from any reasonable cause.

RULES GOVERNING THE SUPPLY OF LIGHTING AND POWER TO EXHIBITORS IN THE DEPARTMENT OF ELECTRICITY.

Electric power only will be supplied in the electrical building. The aisles of the building will be illuminated with arc lamps without cost to exhibitors; additional lighting to be paid for by exhibitors at the following rates:

Arc lamps, service May 1st to October 31st, 1893, during exposition hours, $65.00 per lamp of 2,000 nominal candle power. Lamps suspended from ceiling with opal globes and globe nets; special fixtures or globes, or special ornamental lamps, will be subject to an extra charge to be fixed by the director-general and the director of works.

Incandescent lamps, service May 1st to October 31st, inclusive, 1893, during the hours of the exposition, $8.00 per 16 candle power lamp, including installation of first lamp and socket and lamp renewals. Breakages must be purchased by exhibitor of the contractor lighting his space, at the usual commercial rate. Lamps will be hung on plain cord or pendant. Special or fancy wiring will be furnished at an extra charge to be fixed by the director-general and the director of works. Fixtures and shades will be furnished and maintained by consumer. Special colored or fancy lamps, or lamps other than 16 candle power, will be subject to special agreement with the director-general and approved by the director of works. Installations of 300 lamps or more will be subject to special discount to be fixed by the director-general.

MOTORS.—Exhibitors requiring motive power will furnish necessary motors, rheostats, main line switches, insulating base, etc., complete, together with all belts, counter-shafting, and other means of connecting motors to operating machinery. Motors should be suitable for operation on the class of circuit furnished in exhibitor's location.

The rheostats must be constructed wholly of non-combustible material. The main line switch shall be of the knife blade type, of ample carrying capacity, and suitable for breaking current at the potential used. Motors shall be erected in position at the expense of the exhibitor by the contractor furnishing power in the location of his exhibit, service connections to motors being installed, maintained and owned by the said contractor.

Charges for service connections with the main line will be as follows:

For one-half horse power and less, $8.

For one horse power to five horse power, per horse power, $12.

For more than five horse power and not exceeding ten horse power, per horse power, $10.

For more than ten horse power, per horse power, $8.

Fractions of a horse power will not be considered, except for motors of less than one horse power.

Ratings of motors will be the standard rating of the manufacturer.

Charges for service will be based on the maximum electrical horse power delivered to the motor, irrespective of the class of work to be operated by the motor, at the following rates:

For ¼ horse power and less, $15.

For more than ¼ horse power, and not exceeding ½ horse power, $30.

For more than ½ horse power, and not exceeding one horse power, $50.

For more than one horse power, and not exceeding two horse power, per horse power, $45.

For more than two horse power, and not exceeding three horse power, per horse power, $42.50.

For more than three horse power, per horse power, $40.

A limited amount of power may be furnished to exhibitors free of charge to simply turn over an otherwise inoperative exhibit.

LETTERS TO THE EDITOR.

EFFICIENCY OF ALTERNATING PLANTS.

IN the letter under this head in THE ELECTRICAL ENGINEER of Dec. 14, W. H. C. is evidently aiming in the right direction when he asks, "Can so large a loss be due to the inefficiency of the transformers?"

Taking his own figures, given in the letter, he has 1,299 lights wired up on 97 transformers. Assuming that he has a transformer capacity of 1,300 lights, this would average 13 lights per transformer. If we take the figures given by Mr. L. B Stillwell in his paper read before the National Electric Light Association at Buffalo, Feb. 23, 1892 (an abstract of which is printed in THE ELECTRICAL ENGINEER, of March 2, 1892, page 214), and assuming that the transformers are of 10-light capacity each, the iron loss would be five per cent. at full load as given by Mr. Stillwell in his paper; and this would give a reading on the station ammeter of 3.25 amperes according to the following calculation: 1,300 light transformer capacity. Assuming 1 ampere per light, and the ratio of transformation to be 20 to 1 would give 65 amperes required to run transformers fully loaded. 5 per cent. for iron loss, that is, 5 per cent. of sixty-five = 3.25 amperes on station ammeter. This loss is constant whether lights are burning or not.

W. H. C. also gives the actual revenue as $725.60, with the consumer's rate at 1 cent per ampere hour; this gives 72,560 ampere hours by meter for the month. He also says that they run eight hours per day and thirty-one days to the month; this gives 293 as the average amperes per hour for the month from house meter readings.

Assuming, as before, 1,300 light transformer capacity, this gives less than 25 per cent. as the average load upon the transformers; this would run up the relative iron loss to about, or over, 20 per cent. and reduce the efficiency of transformers to 80 per cent., or less, on the average. This accounts for about one-half of the difference between the station readings, as given, and the house meters.

It may be that some of the house meters do not work properly or are interfered with by the consumers of light, or that they tap the wires before reaching the meters, or that the transformers are less efficient than here assumed.

The coal burnt per hour is 5.49 pounds per electrical horse power at the station for the month, which certainly should be reduced.

W. H. C. makes a fair showing, however, when he takes his reading from log book for Sunday and Tuesday, as follows :

	Sun.	Tues	Difference in amperes.	
Total ampere hours.	154	214	61	Hours and coal burnt on Sun. and Tues. on a run of 8 hours.
Coal consumed.	1,500	1,750	250	

61 (ampere hours) × 1,100 (volts) ÷ 746 (watts) = 90 E. H. P. hours nearly. $\frac{250}{90}$ = 2.8 pounds of coal per E. H. P. hour which I should say was very good, judging from what his plant is like from the reading of his letter. I should also be inclined to think he had excessive friction in engine or leaks in the steam system.

I should favor adding to W. H. C.'s log-book records, the following : (1). The number of pounds of water used during each run taken from meter in feed pipe to boiler. (2). Boiler guage readings at the end of each hour. (3). Wattmeter readings for each run from meter in the mains. These would enable him to check the run month by month and to note any change in the coal burnt and in the running expense of the station and help to locate each fault and correct it.

PITTSBURGH, PA. C. M. GREEN.

WITH reference to "W. H. C.'s" letter in THE ELECTRICAL ENGINEER of December 4, I do not think that the causes of the apparent discrepancy to which he alludes are far to seek.

The estimate that twenty lamps would call for only one ampere at the station is, of course, quite wrong. From the figures given it is evident that each lamp requires $\frac{6022}{72560}$=0.083 ampere at the station, or about twelve lamps to the ampere; 0.083 ampere at 1,100 volts is 91.3 watts.

Now, an ordinary 16 c. p. lamp takes nearer seventy watts than sixty. This gives an efficiency of, say, 73 per cent. roughly. Of the remaining 17 per cent. the line losses would account for, say, 4 per cent., leaving 13 per cent to locate.

Now, "W. H. C.'s" transformers are very small, averaging only 13.4 lamps each, and they are necessarily underloaded during part of the run. Might not they alone account for the whole of this 13 per cent?

But there is yet another factor to be considered. If you are thinking about power you must not trust too implicitly to an ammeter when using an alternating current, be the volts ever so constant; for unless the current be in step with the E. M. F. the ammeter, though it will correctly indicate the current, will, nevertheless, lead you to overestimate the power in a way which is well known, but is too complex to explain here. Now, as the plant is not shut down till midnight, the transformers are underloaded during a considerable part of the run, as, indeed, the table given shows, and in this case the current cannot be exactly in step with the E. M. F.

Taking these considerations into account, I do not think that "W. H. C." will be able to materially reduce the apparent discrepancy. Indeed, he is to be congratulated that he does not have to keep the potential on the mains twenty-four hours a day. If he did, the apparent discrepancy would be far greater.

December 17, 1892. N. W.

I HAVE read the article of "W. H. C." under the above title, but from the data given it would be impossible to locate the trouble. It is not inefficient *generation* of current that "W. H. C." complains of, as he draws his conclusions from the difference between his station amperemeter readings and the readings of the house-meters. This would leave out of consideration the efficiency of the dynamos, and would show that the "leakage" took place between the plant and the lamps of the consumer. As the total lamp capacity of the 97 converters is not given, it cannot be stated whether or not the converters are underloaded.

It would seem to me likely that the discrepancy may be due to a little of everything; a little line drop, a little of too many converters for the load, a little inefficiency in the converters, and a little sluggishness of the meters. It is wonderful how a number of little things, when piled on top of each other, will mount up.

A. W. MESTON.

ST. LOUIS, MO.

THE DESIGN OF THE LUNDELL MOTOR.

THE writer would like to say a word or two about the type of motor described in THE ELECTRICAL ENGINEER of Dec. 7, under the name of the Lundell Motor.

In the Fall of 1888 the writer designed and built for the Cleveland Motor Company, of New York, a 1 h. p. motor of the type since adopted by the Interior Conduit and Insulation Company, and called the Lundell motor. A glance at the cuts representing the so-called Lundell motor will show the reason why such a type of motor will be less efficient and more costly than other motors of good types, and consequently why the writer abandoned the type.

It is just as important that the wire of the field coil should include the necessary cross section of iron with the minimum length of wire, as in the armature. In the type of motor under discussion the cross section included by the field coil is many times larger than the necessary cross section of iron for the magnetic circuit. The consequence is that the length of wire per turn is much increased, thereby increasing the watts consumed in the field coil, and at the same time greatly increasing the cost of field, in labor and material. The writer proved this by using the same armature in motors of two types now widely used, the conditions otherwise being the same, and found that the motor having the field coil surrounding the armature concentrically, as in the so-called Lundell Motor, consumed more than double as many watts for exciting the field, and that the cost of wire and labor was in proportion. The cost of winding and wire is an item of considerable importance in machines for constant potential, needing fine wire for the shunt, and especially for high potential motors.

NEW YORK CITY.

LEGAL NOTES.

EDISON VS. SAWYER-MAN.

EDISON ELECTRIC LIGHT COMPANY AND EDISON GENERAL COMPANY *vs.* SAWYER-MAN ELECTRIC COMPANY.

IN pursuance of the decision of December 15, the United States Circuit Court of Appeals made the following order, December 19 :

This cause having come on to be heard on appeal from the order of the Circuit Court of the United States for the Southern District of New York, entered herein November 19, 1892, granting a preliminary injunction against the defendant, and counsel for the respective parties having been heard by the court upon the said appeal, it is

Ordered that the said injunction order appealed from be modified so as to cover only lamps made in infringement of the second claim of the patent in suit, and also by inserting a provision reserving the right to the defendant to move hereafter for the vacation, suspension or modification of the injunction upon proof of specific instances of refusal on the part of the complainants, or either of them, to supply the lamps of the patent, upon terms reasonable under the circumstances of the particular case, to the owners of electric lighting apparatus which was installed or purchased before the rendition of the interlocutory decree of the Circuit Court sustaining the validity of the patent for use with such apparatus, and that the order, as so modified, be affirmed.

And it is further ordered that a mandate issue to the said Circuit Court directing the said court to modify the said injunction order as above stated, and to proceed herein according to law and justice and to the opinion of this court.

LITERATURE.

Wissenschaftliche und Technische Arbeiten von Werner Siemens. Vol. II. Technical Works. 2nd Edition, Berlin, 1892. Julius Springer. X +, 601 pp. 6x9 inches. Price, $3.80.

THE recent death of Werner von Siemens makes this a fitting time for a review of the work of one who had devoted his lifetime to the furtherance of science, and of the electrical arts in particular. There is probably no field of electrotechnics in which Siemens has not done some work, and few in which he has not distinguished himself. A record of such work must therefore not only be valuable from an educational standpoint, but highly entertaining at the same time. The present work is a complete record of electrical and other technical work of Siemens, beginning with the description of his first patent for the obtaining of a gold plating solution, in 1842. It takes us through all the telegraph work of this great inventor, gives the original description of the Siemens polarized relay, and carries us through various stages of the Siemens armature up to the discovery of the principle of the dynamo electric machine. The work is compiled from the original sources and is brought up to within the last year, and so may be said to contain practically all of Siemens's work. It is a most remarkable record, and if, as has been truly said, "A man's works are his monument," Werner Siemens needs no bronze tablet to perpetuate his memory.

The book is well illustrated from original drawings and is in every way got up in a manner worthy of the subject.

RELATIONS OF THE GENERAL ELECTRIC AND WESTINGHOUSE COMPANIES.

RESPECTING a rumor that the contract for lighting the World's Fair has been turned over to the General Electric Company by the Westinghouse Company, we are authorized to say that it is wholly unfounded and that the Westinghouse Company has had no negotiations, either directly or indirectly, with the General Electric Company, or with any of its representatives looking towards the turning over of this contract, or towards a union of interests. The Westinghouse people claim that with their new lamp, at the low prices quoted, without infringing the Edison patents, with their business now earning at the rate of 15 per cent. per annum, with orders on hand to keep their factory running night and day, with representatives of local companies of the General Electric Company coming to ask terms for the use of the new lamps—with these advantages they claim that there is every reason why their independent course should be maintained, in the interests of their stockholders. They say that the addition to the works of the company now being completed will raise the capacity of all of its shops to an output of $10,000,000 per annum

PERSONAL.

MR. FRANCIS R. UPTON, who has so long been the manager of the Edison Lamp Works, has now been made general manager of the incandescent lamp department of the General Electric Company. The position and honor have been won by long years of hard work in a peculiarly difficult field of electrical industry, and Mr. Upton will receive the personal congratulations of a host of friends.

HON. GARDINER C. SIMS has just returned to New England from a long Southern trip. He found on his arrival home that he had been appointed arbitrator for the city of Providence on its new contract with the Narragansett Electric Lighting Company.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED DECEMBER 13, 1892.

Accumulators:—

Manufacture of Secondary Battery Electrodes, W. W. Griscom, Haverford, Pa., 487,834. Filed Sept. 30, 1892.

Employs a grid consisting of a group of supporting frames filled with thin sheets separated from one another slightly and the spaces filled when the sheets are sufficiently converted into active material.

Alarms and Signals:—

Signaling Device for Railways, Z. Krulis, Chicago, Ill., 487,904. Filed Mar. 28, 1892.

An automatic track signal in which the circuit is closed by the car in passing over a pin projecting slightly above the rail.

Electric Signal Circuit, J. V. Young, Boston, 488,138. Filed June 29, 1892.

System of electric block signals for steam railways.

Contact Rail, F. E. Kinsman, Plainfield, N. J., 487,752. Filed Feb. 23, 1892.

Consists of a rail having a contact edge or corner in combination with a circuit closer adapted to make longitudinal rubbing and side contact with the edge of the rail.

Conductors, Conduits and Insulators:—

Insulator, C. Wirt, Chicago, 488,046. Filed Jan. 4. 1892.

Consists of two parts each provided with an eye and hook at one end and one with a cup and the other with a body adapted to be received within the cup; the opposed surfaces of both being corrugated and a mass of insulation filling the intervening space and entirely surrounding both the cup and the body.

Process of Insulating Electric Conductors, C. Cuttriss, New York, 488,141. Filed Jan. 20, 1892.

Has for its object to render available for purposes of insulating electric conductors raw cotton in the form known as sliver.

Dynamos and Motors:—

Armature for Electro-Magnetic Machines, R. Lundell, New York, 487,755. Filed Feb. 5, 1892.

Employs an armature core having a series of holes near each edge, a series of U-shaped conductors insulated from the core, the legs of which extend through the holes and means for causing each conductor to grasp the core.

System of Electrical Transmission of Power, N. Tesla, New York, 487,796. Filed May 15, 1888.

Claim 3 follows:

The combination with a multipolar alternating current machine having independent induced or current generating circuits, of motors having independent energizing circuits and a smaller number of poles than the generator.

Automatic Safety Device for Dynamo Electric Machines, F. B. Badt, Chicago, Ill., 487,816. Filed Feb. 19, 1892.

Employs a responsive device in the main circuit, connections whereby a local circuit is closed when the main current has reached a pre determined maximum, and a circuit changer to throw resistance into the circuit and controlled by the responsive device.

Armature for Electric Machines, B. G. Lamme, Pittsburgh, Pa., 488,016. Filed Feb. 8, 1892.

Claim 1 follows:

The combination with a drum armature core having radiating teeth of separately wound coils placed within the spaces between the teeth each, coil spanning several teeth.

Electric Motor, I. E. Storey, Boulder, Colo, 488.041. Filed Feb. 4, 1892.

Employs a field magnet consisting of a cylinder surrounding coils of wire in combination with pole pieces extending from opposite points at the edges of the cylinder and other pole pieces extending inward from about midway between the edges of the cylinder and embracing the coil.

Galvanic and Thermo-Electric Batteries:—

Galvanic Battery, H. T. Johnson, New York, 487,839. Filed April 1, 1892.

A battery in which the positive electrode forms the case and the negative electrode is placed within, depolarizing and exciting agents being placed between the two electrodes together with a lining of absorbent material.

Lamps and Appurtenances:—

Casing for Bases of Incandescent Lamps, G. R. Lean, Boston, & C. B. Burleigh, Chelsea, Mass., 487.816. Filed Nov. 27, 1891.

A casing made in two parts, one ring shaped and the other cup shaped, the latter extending above the lower end of the base and compressing a packing between itself and the former.

Manufacture of Incandescent Electric Lamps, C. Pauthonier, Boston, 487,890. Filed April 20, 1892.

Method consists in first sealing the leading-in wires into the bulb, then introducing the filament into an opening into the bulb and affixing it in conductive relation to the electrodes after which the vacuum is formed and the bulb is sealed.

Incandescent Lamp, E. W. Applegate, Omaha, Neb., 488,139. Filed April 7, 1892.

A separable incandescent lamp made with the object of having its filaments readily replaced in case of breakage.

Measurement:—

Electric Meter, C. W. Ayton, New York, 487,703. Filed Dec. 5, 1891.

Employs an ammeter or similar instrument the needle of which is attracted at periods of time, in a direction at right angles to its normal direction of movement, and closes one or more circuits according to the amount of current actuating it.

Time Meter for Electric Lighting Systems, J. O. Ball, Mount Pleasant, Iowa, 488,107. Filed Feb 20, 1892.

Employs a movable registering device and a cut-off connected therewith and adapted to throw it into and out of engagement with a clock mechanism when the circuit is closed or open.

Miscellaneous:—

Speed Indicator, W. H. Abbott, Lennoxville, Canada, 487,702. Filed Aug. 12, 1891.

Employs a mechanism adapted to make and break a circuit at each revolution of the wheels, and a clock having a movement providing a switching device by which two sets of electromagnets are alternately brought in and out of the circuit, the speed in miles per hour being indicated on the dial.

Means for Transmitting Power, W. E. Walsh, San Francisco, Cal., 487,805. Filed May 2, 1892.

Magnetic Separator, H. S. Chase, Boston, 488,064. Filed Jan. 29, 1892.

Railways and Appliances:—

Conduit for Electric Railways, J. W. Hayden, Ft. Wayne, Ind., 487,785. Filed Jan. 16, 1892.

Consists of a closed slotted box terminating in a drain at its lower end and having the trolley supports at one side and protected by an overhanging flange.

Trolley Catcher, J. Werling and J. P. Agnew, Minneapolis, Minn., 487,808. Filed Feb. 25, 1892.

Consists of a retractile device connected with the lower end of the trolley pole rope and means for tripping the device in the event of the trolley rising above the wire.

Electric Railway Trolley, A. Woerner, Buda-Pesth, Austria, Hungary. Filed Feb. 8, 1892, 487,818.

Consists of a frame and a long roller instead of the grooved trolley wheel in ordinary use.

Electric Railway Trolley, D. Mason, New York, 488,022. Filed Nov. 11, 1889.

Employs a contact device making underneath contact with the trolley wire, a pole carrying said contact device and a flexible resilient support for the pole.

Electrolytic Apparatus, T. Craney, Bay City, Mich., 487,996. Filed Jan. 4, 1892.

Lightning Arrester, W. R. Garton, Keokuk, Iowa, 483,002. Filed July 11, 1892

Consists of a solenoid having an armature provided at one end with a guide rod which receives a flexible conductor and at the opposite end of the carbon rod in combination with a pair of serrated plates with their faces near each other but out of contact, the one connected with the ground and the other with the carbon of the armature.

Electric Gas Lighter, L. M. Kilburn, Council Bluffs, Iowa, and S. Van Etten, Omaha, Neb., 488,012. Filed Mar. 21, 1892.

Electric Belt, O. Kjorstad, Eau Claire, Wis., 488.013. Filed May 11, 1892.

Automatic Regulator, E. J. Houghton and W. White, 483,121. Filed Mar. 26, 1892.

An apparatus which automatically introduces into the circuit more or less resistance according as the E. M F. of the current is greater or less.

Electric Coupling, J. J. Purcell, Washington, D. C., 488,027. Filed June 18, 1892.

An air-tight case containing an insulating material completely covering the junction of two underground cables.

Electric Railway Trolley, D. Mason, New York, 488,023. Filed March 3. 1890.

Employs a spiral spring coiled on a horizontal axis and connected with the car and exerting an upward pressure upon the pole.

Switches and Cut-Outs:—

Automatic Switch, N. Newman, Springfield, Mass., 487,881. Filed Aug. 2, 1892.

Relates to means for automatically closing or breaking a circuit at some premeditated time.

Spring Jack Switch, C E. Scribner and E. P. Warner, Chicago, 488,083. Filed July 3, 1888.

Provides means for readily looping or connecting metallic circuits.

Electrical Safety Cut-Out, H. S. Keating, London, Eng., 488,123. Filed Aug. 31, 1892

Consists of a U-tube hermetically closed at one end and containing mercury above which is a charge of nitrogen adapted to expand and break the circuit.

Telegraph:—

Automatic Keyboard Operator, H. S. Prentiss, Elizabeth, N. J., 487,936. Filed June 19, 1891.

Employs a series of contact closers, a series of switches operated by the passage of a perforated strip between the circuit closers, and a main circuit closer for closing the circuit through the contacts set by the switches.

Printing Telegraph, C. L. Buckingham, New York, 487,981. Filed Nov. 10, 1888.

Employs a type wheel having four rings of type in combination with apparatus for adjusting it in one direction or the other from an intermediate position on its axis.

Printing Telegraph, C. L. Buckingham, New York, 487,982. Filed Apr. 24, 1890.

Has for its object to produce a type telegraph by means of which messages may be printed as rapidly as they are produced by the Wheatstone system, while employing only about the same number of main line pulses.

Printing Telegraph, C. L. Buckingham, New York, 487,983. Filed Apr. 29, 1890.

Similar in its object to 487,982.

Synchronous Multiple Telegraph, C. L. Buckingham, New York, 487,984. Filed Apr. 30, 1890.

Employs a synchronizing arrangement consisting of a battery at the receiving station, a duplex relay at the transmitting station and a local circuit, by which a unison motor is controlled.

Printing Telegraph, C. L. Buckingham, New York, 487,985. Filed Dec. 14, 1889.

Enables spacing between words while the wheel remains in its initial position, and by the repeating of the characters in a message while the wheel remains in a fixed position and adjusted to print such characters.

Printing Telegraph, C. L. Buckingham, New York, 487,986. Filed Apr. 25, 1890.

Relates to the application of printing mechanism to the synchronous multiple telegraph.

Telephones and Apparatus :—

Multiple Switchboard Signal, G. Taintor, Keene, N. H., 487,795. Filed Apr. 7, 1892.

Employs an auxiliary resistance normally in circuit with the central station connecting apparatus, a normally discontinuous shunt circuit around said resistance, and a circuit closer mounted in a plug socket connected with the main line circuit of the annunciator.

Multiple Switchboard Circuit, A. H. McCulloch, Boston, 487,852. Filed Mar. 9, 1892.

Invention consists in combining a peculiarly constructed call annunciator and the main circuit within which it is included with two sources of electricity and means for connecting both with the circuit at the same time by the act of sending the out-going signals.

Multiple Switchboard Busy Test Circuit and Apparatus, J. L. McQuarrie, Boston, 487,853. Filed Apr. 7, 1892.

Has for its object to provide a system of test appliances which shall be efficient without unnecessary complication in circuits or apparatus.

Busy Test Apparatus for Multiple Switchboards, J. L. McQuarrie, Boston, 487.854. Filed Apr. 7, 1892.

Provides means for testing a line at any one section of a multiple switchboard to see if it is already in use at another section.

Means for Preventing Induction in Cables of Multiple Switchboards, 488,084. Filed Mar. 5, 1882. C. E. Scribner, Chicago. Ill.

Invention consists of a third wire connected at one extremity to that side of the line circuit which opens when connection is made to a line twisted with the wires constituting two sides of the line circuit into a triple strand extending through the cable connected to the spring jacks and to the annunciator and terminating in an open extremity.

Multiple Switchboard System for Telephone Exchanges, C. E. Scribner, Chicago, 488,035. Filed May 17, 1892.

Has for its object to automatically render the individual annunciator of the line inoperative when the connection is established with any spring jack of a line without including any contact points in the line circuit.

Multiple Switchboard System for Telephone Exchanges, C. E. Scribner, Chicago, Ill., 488,036. Filed Apr. 16, 1892.

Consists of a normally open shunt about the individual annunciator of the line and means actuated by an electromagnet to close the shunt circuit while a connection exists to the line.

Telephone Switchboard Apparatus, C. E. Scribner, Chicago, Ill., 488,037. Filed April 16, 1892.

Similar in its object to 488,036.

Multiple Switchboard System for Telephone Exchanges, C. E. Scribner, Chicago, Ill., 488,038. Filed April 18, 1892.

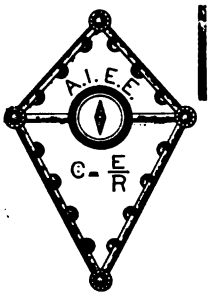
Similar in its object to 488,036.

Test Circuit for Multiple Switchboards, O. A. Bell, Brooklyn, N. Y., 488,058. Filed March 12, 1891.

Has for its object to provide means whereby a line which is in use may give the busy test, which means however shall not have any electrical connection with the telephone line itself.

SOCIETY AND CLUB NOTES.

PROPOSED BADGE OF THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.



Proposed Institute Badge. Twice Actual Size.

THE American Institute of Electrical Engineers has for years contemplated the adoption of some type of badge or pin similar to those of the various engineering societies, and the present committee which has the matter in hand has presented a large number of models and designs of more or less merit and originality. One of these which seems to meet with general approval and is certainly characteristic of the profession of electrical engineering, was presented for consideration to the Council and the Institute by its designer, Mr. W. J. Hammer, of the committee, with a view of securing a full criticism by the members. THE ELECTRICAL ENGINEER to give the matter still wider publicity herewith presents an explanation of the pin and on behalf of the committee requests any members who desire to submit new designs or suggestions for changes in this one, to forward them to the secretary, Mr. Ralph W. Pope, No. 12 West 31st street, New York City.

As will be seen, the pin represents Franklin's kite, which demonstrated the identity between lightning and electricity. It represents static electricity and is a recognition of America's first electrician and philosopher. The arms of the kite form a diagrammatic representation of Wheatstone's bridge. The binding posts at the corners are small pearls, but in the original design were gold balls which are perhaps preferable.

In the centre is a galvanometer, representing magnetism and induction; the needle is of blued steel placed under a piece of amber. The amber which is enclosed within a ring of gold, represents the first conception of electricity dating back to B. C. 600, when Thales the Greek philosopher recorded the fact that amber when rubbed attracted light particles to it, and the Greeks worshipped it, believing the gods had endowed it with life. In A. D. 1600, Dr. Gilbert, court physician under Queen Elizabeth, coined the word electricity from the word elektron, the Greek name for amber.

Above the galvanometer are shown the initials of the Institute, A. I. E. E., and below Ohm's law, $C = \frac{E}{R}$. Underneath this upon the original design was the date 1884, in which year the Institute was organized but this was objected to as giving the pin too much the character of a college class pin. Around the edge was engraved "What hath God wrought," the first message sent by the Morse telegraph. This was objected to as identifying the pin with a particular department of electrical work while otherwise the pin is general in its signification. It is proposed to make it a trifle larger and the gold wire forming the arms of the bridge will be somewhat smaller. Mr. Hammer has left the pin at the office of THE ELECTRICAL ENGINEER, where it may be seen by those who may care to inspect it.

THE DISSIPATION OF ENERGY IN HERTZ RESONATORS.

IN the article on the above subject by Prof. Bjerknes, appearing in our issue of Dec. 14, two errors are pointed out, due to misprints in the original source, the *Comptes Rendus*.

The period of oscillation should be 1.4×10^{-8} (not 14×10^{-8}). Four words are omitted from the last sentence, which should read: "That metals are more transparent to Hertzian undulations than to luminous undulations."

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

Prosperity and profit are promoted by persistent publicity.

CONSOLIDATION OF THE ELECTRIC LIGHTING INTERESTS IN CLEVELAND, OHIO.

IT has recently come to light that the General Electric Company has consummated a deal with the local electric lighting companies, whereby the franchises and business of the "Cleveland Electric Light Company" and the "Brush Electric Light and Power Company" are transferred to the new organization known as the "Cleveland General Electric Company." This latter company was incorporated with a capital stock of $25,000, which was soon afterwards increased to $1,000,000. Last winter a bill was introduced into the legislature giving the city the right to issue bonds for the purpose of installing a municipal plant, with the hope of obtaining better service, and of furnishing light to a larger territory. As this is also one of the objects of the new company, the explanation of the consolidation is no doubt an effort to defeat the above bill. The two local plants will continue operating as usual for the present, but in all probability the new station which is spoken of will be simply an addition to the one occupied at present by the Brush Company, not only because of its very central location and adjoining vacant territory, but also because of the abundant water supply and the ease in handling fuel.

At this station will be located all the arc and alternating machines, and the building now used by the Cleveland Electric Light Company will contain the direct current and power generators for stationary motor work. The new company will no doubt do much to better the lighting industry of the city. Prices should go down and service go up, and means will be forthcoming for the placing of the wires underground, where they were ordered to be put by ordinance more than a year ago, but with which ordinance the present companies are really in no position to comply, because of their small patronage.

Cleveland has a population of 300,000, yet the combined business of the present companies is only about 1,600 arcs and 12,000 incandescents, which indicates that there is a large field for development. If the city starts in aright with this new company, it will not only request, but enforce its request for, a compliance with the underground ordinance, at least in the business portion of the city, and once started by the lighting companies it will be a matter of but a short time before the feeders for the railroads are also out of sight. The local telephone company by February 1, 1893, will have 2,000 miles of its wires beneath the surface.

W.

THE DE RYCKE "STRAIGHT LINE" CENTRIFUGAL SEPARATOR AND GREASE EXTRACTOR.

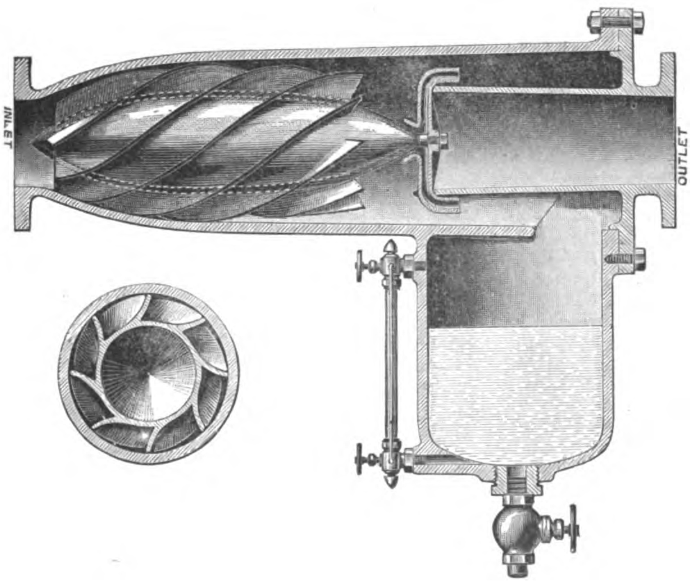
In the interest of economy, it becomes a necessity that all engines should be supplied with steam from which all entrained water and grease has been extracted. This result can be accomplished, it has been demonstrated, by the use of a thoroughly reliable separator, connected between boiler and engine, or between engine and condenser. Of those to which we may justly call attention as coming under this head is the device shown in the accompanying engraving, representing the De Rycke "Straight Line" Centrifugal Separator and Grease Extractor, which is manufactured by Joseph De Rycke, of No. 145 Broadway, N. Y.

The separator and extractor, which is shown in the accompanying engraving, consists of a shell or casing in which there is firmly secured a stationary double-ended cone. On this cone there are cast a number of knife-edged wings, extending spirally along its exterior, the annular space between the cone and shell of the separator being equal at its smallest cross-section to that of the steam pipe, from whence it is greatly enlarged. At the outlet end of the shell there is also an annular space, formed by an inverted outlet pipe. On entering the separator the steam is spread and thrown outward by the cone and given a centrifugal motion by the spiral wings. These wings are constructed with curved surfaces tangential to the cone, which is an important factor in the construction of the separator, as it materially aids in producing an outward impulse to the water or grease.

The steam on entering the separator is immediately expanded from a compact volume (due to the size of the pipe) into an annular space of equal volume, whereby its particles are removed farther from the centre, and thereby can receive a greater amount of centrifugal force. Under these favorable conditions the entrained water, grease, etc., meets curved angular wings along which it flows outward to the shell of the separator, and is collected in a well of ample proportions. Here it is entirely isolated from the flow of the dry steam, which passes off through the inverted pipe.

By subdividing the steam into a number of separate channels, every particle of the entire volume is sure to be acted upon, and the entrained water by being whirled along the shell and lodged in a separate chamber or receptacle is positively isolated from the flow of the dry steam, thus avoiding all possibility of its being picked up again or producing condensation by contact.

The Edison illuminating and power companies of New York, Pennsylvania, Ohio, Indiana, California, Texas, Rhode Island and Wisconsin are using these separators and extractors. They are also being placed in all new installations of the General Electric Company. Some of the electric light plants have from six to twenty-two of the De Rycke separators in use, varying in size from four to eighteen inches diameter of pipe. We notice that this device is also extensively used in electric street railway plants, on steamboats, and in mining and manufacturing plants.



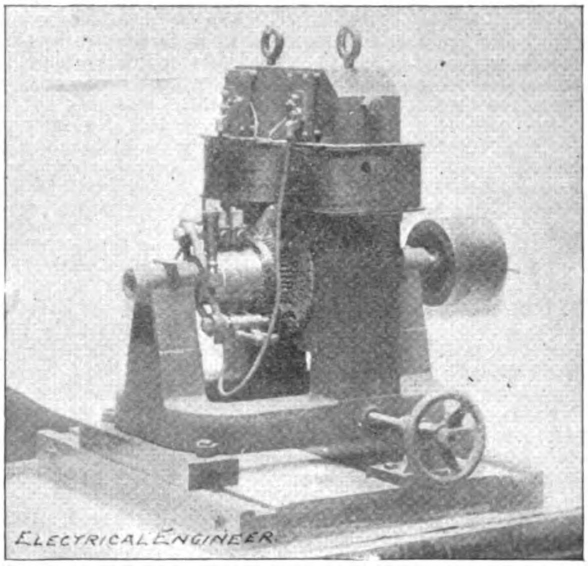
The De Rycke Centrifugal Separator.

Mr. De Rycke also manufactures a vertical "Straight Line" separator, which differs but slightly from the horizontal device, which we have described.

THE "COMMERCIAL" DYNAMOS AND MOTORS.

Constant potential motors and dynamos of moderate capacities may now be fairly said to have become a staple article of manufacture. In every large town and city hundreds and thousands of these machines may be found, doing the numerous classes of work for which they are adapted, silently, regularly and efficiently.

The line of machines from ¼ to 50 h. p., manufactured by the Commercial Electric Company, of Indianapolis, Indiana, under the patents of Mr. A. D. Adams, are designed to meet, in a high degree, the exacting requirements of this extended use. The aim in the design of these machines has been to produce only the best, and it is believed that this determination, coupled with several novel methods of construction, has resulted in a line of dynamos and motors, having all the desirable features, viewed from the user's standpoint.



The Commercial Dynamo and Motor.

The following are some of the characteristic features of these machines: All field magnet frames are made of forged wrought iron throughout, no cast iron being used in them. As a result of this construction a lighter, more sightly and more efficient machine is obtained. No other company in the United States, it is claimed, is using forged wrought iron, exclusively, for field magnet frames.

Gramme armatures of large diameter are used in machines from ¼ to 10 h. p., giving ample room for the many turns of wire required on these small machines for high pressure and insuring non-liability to burn-outs and affording ease of repair. Armatures in machines from 1 to 10 h. p. capacity are wound with but one layer of wire for the 110 volt pressure and but two layers for the 220 and 500 volt pressure, another feature which renders burn-outs unlikely and repairs easy. The point of commutation in these machines is constant under all changes of load within the capacity of the machines, due to the great strength of the field magnet and few turns of wire on the armature.

All starting boxes and rheostats are constructed entirely of incombustible material, with slate fronts. All terminal boards for mounting connections on motors and dynamos are of slate and all binding screws and binding posts of ample current carrying capacity and mechanical strength. All machines of 1 h. p. and over are provided with insulating sliding bases and belt tighteners.

The above points will, no doubt, be highly appreciated by those experienced in the setting up and operation of dynamos and motors.

MR. MACKAY'S CHRISTMAS TREE.

Mr. John W. Mackay has again sent over the Commercial cables his Christmas and New Year's greetings to the staff on the lines, accompanied by a "Christmas Box" in the shape of an order for the payment of an extra half month's salary.

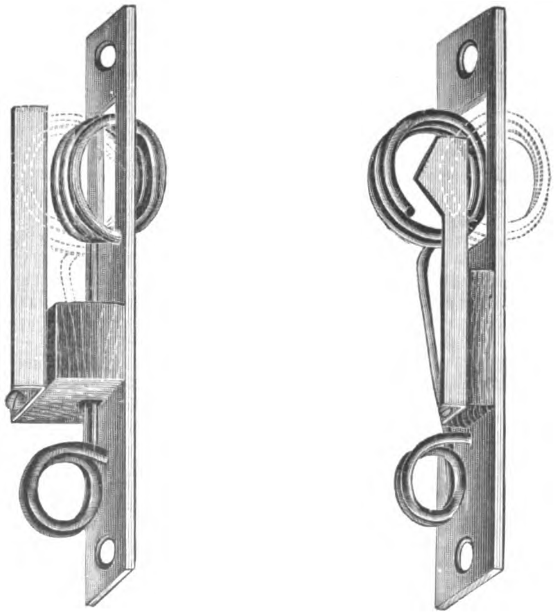
Mr. Mackay in his message complimented the men on their work during the year just closing and said he felt sure of the continuance of their co-operation in maintaining the leading position of the Commercial Cable Company. The "Commercial" staff are highly fortunate in being thus remembered.

THE FIRE IN THE BUFFALO, N. Y. STATION.

A BAD fire occurred on Friday, Dec. 16, at the Court street station of the Buffalo General Electric Company, followed up, in quick succession, by the break down of the big Corliss engine in the Wilkeson street station, by the snapping of the piston rod. Mr. C. R. Huntley, the general manager of the company, writes us on Dec. 19: "It is very unfortunate that the fire should have occurred just at this time of year, but we are not as badly crippled as we at first supposed. Our engines and boilers are in shape to run, and in fact on Friday night (the fire occured on Friday morning at 5 o'clock) we had four generators for arcs running in the station. The fire originated at the switchboard and ruined all the dynamos and electrical apparatus. We were able to get from Cleveland and from the General Electric Company, by express and special train, apparatus to duplicate everything we had; and if nothing goes wrong with us, by to-morrow night the public will not know we have had a fire. Through the various stations we have been able to couple things together, and the city has not been without light any night. Many of our customers on the incandescent circuits have been taken care of from some of the other plants. We shall use the same building, as it was not injured very much, being a well constructed one so far as fire is concerned."

THE "HARD" WINDOW AND DOOR SPRING.

THE protection of buildings from thieves and other trespassers has given rise to a variety of forms known as window springs, and among these are devices to give an alarm of the raising of a window. This spring must be so designed that a slight raising of the window gives the alarm, while on the other hand the closing of the electrical contact must be absolutely certain in order to insure the attention of the occupants of the house to the attempted invasion. A window spring embodying these qualities in an eminent degree, has been designed by J. Randolph Hard, of No. 2 Howard street, which is illustrated in the accompanying engraving. Fig. 1 shows the window spring which is let into the window frame at the side when the sash is raised. As will be seen, the spring consists of a piece of spring brass, the lower terminal of which is given two or three turns which lie close together, and directly opposite a brass knife edge which forms one side of the circuit, the spring forming the other. In the position shown, the spring is out of contact with the knife edge, and the circuit is open, the sash being cut out; as soon as the window is raised, however, the lower edge of th · sash strikes the spring protruding through and pushes it into contact with the knife edge, as shown in dotted outline, thus closing the circuit and ringing the alarm. There is evidently nothing to get out of order in this arrangement, and the contact is absolutely a certain one, as we have had occasion to learn by experience.

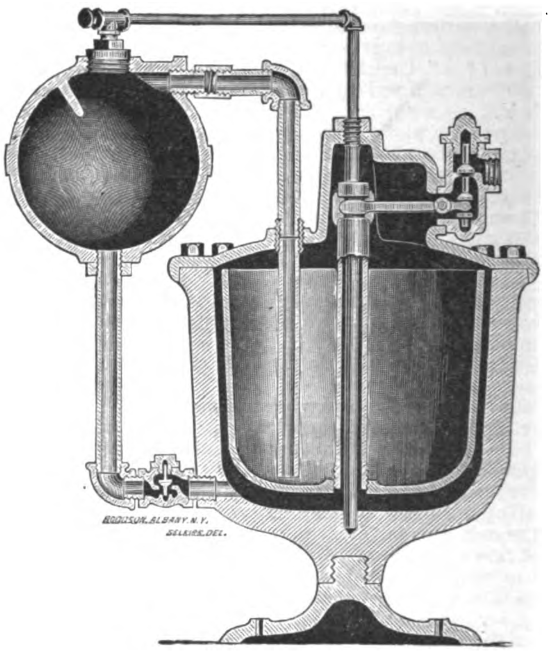


FIGS. 1 AND 2.—"HARD" WINDOW AND DOOR SPRING.

Fig. 2 shows the same principle applied to a door spring, except that the spring is at tension when the door is closed and is released to make contact when the door is ever so slightly opened.

THE "ALBANY" BUCKET RETURN STEAM TRAP.

THE accompanying illustration shows a sectional view of the special bucket return steam trap manufactured by the Albany Steam Trap Company, of Albany, N. Y., which automatically drains the water of condensation from all heating apparatus and returns it to the boiler, whether the coils are above or below the water level in boilers.



"ALBANY" BUCKET RETURN STEAM TRAP.

As will be seen, the equalizing steam valve and the devices for actuating it are wholly inclosed within the trap, thus obviating stuffing boxes and other contrivances. The mechanical arrangement consists of an outside case containing a movable bucket which travels upon a central guide-rod, and is provided with a tube surrounding this rod, the lower end of which is screwed in the bottom of the bucket, and the upper end provided with two lugs for receiving the end of the lever that operates the equalizing valve.

Connected with the trap is a spherical tank, provided with two connecting pipes, one communicating with the annular space exterior to the bucket, as shown with check valve near the lower left side, and the other connecting the upper part of tank with the interior of the bucket, as shown by pipe leading down to near its bottom. The equalizing steam valve is shown connected to the upper right side, and the lever for operating it, with its end inserted between the two lugs of the tube that is screwed in the bottom of the bucket. Both the receiving and discharge pipes are provided with check valves, the one in the receiving pipe opening to the interior of the trap, and thus preventing any water being forced back into the system when the equalizing valve is open, with boiler pressure in the trap. The check in the discharge pipe (not shown) opens to the interior of the boiler and prevents any water from the boiler being forced back into the trap when there is a lesser pressure in the trap than in the boiler.

J. BERLINER.

MR. J. BERLINER, of Hanover, whose "Universal" telephone transmitter is well-known and widely used, has recently established a branch office and factory in Vienna, Austria. The latter will be in charge of Mr. Max Hahn, who has been associated with Mr. Berliner for a number of years.

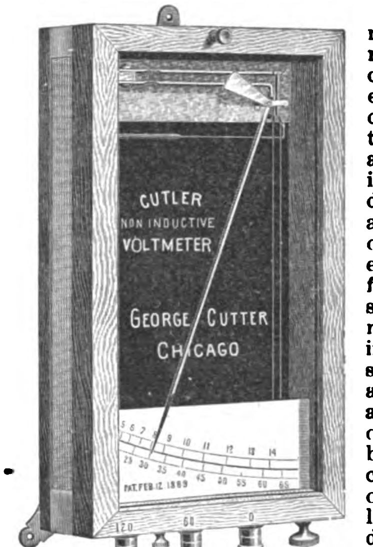
CITY STREET LIGHTING WITH WARD ARC LAMPS.

WE learn from Mr. Edwin S. Tice, manager of the Gladstone Electric Lighting and Power Company (Edision system) of Gladstone, Mich., that the city council has made a contract with the company for street lighting, the Ward arc lamp to be used in the business districts and 32 c. p. incandescents in the residence portions.

THE GLOBE ELECTRIC CORDAGE WORKS.

THE firm of Alfred F. Moore, Third and Race streets, Philadelphia, have purchased the entire plant of the Globe Electric Cordage Works, of 1002 Arch street, Philadelphia, and will carry on the business with the good-will of the latter company.

THE CUTLER NON-INDUCTIVE VOLTMETER.



Cutler Non-Inductive Voltmeter.

VOLTMETERS as well as ammeters when built with magnets, solenoids or magnetizing coils cannot be expected to work equally well under varying conditions, and are apt to be entirely misleading when used on alternating circuits. The reading of any magnetic instrument depends partly on the field around it. so that large masses of iron and steel as found in every dynamo-room will interfere with the correctness of such an instrument. With alternating currents, the coils in an instrument offer an extra resistance due to self-induction and this varies with the rate of alternations. Thus while the ordinary voltmeter may have been carefully calibrated for a current with a certain number of alternations per minute, a little change in the speed of the dynamo will render it inaccurate.

For these reasons there has been a demand for a voltmeter using no magnets, armatures or coils, and this is met by the "Cutler Non-Inductive Voltmeter" shown in the cut. This is built on the same general lines as the ammeter recently illustrated in our columns, the movements of the needle depending on the difference in expansion of two fine wires. One of these carries the current and does the measuring, while the other compensates for changes in temperature of the room. The binding posts are protected by rubber covers and are placed at the lower edge, while the resistance used in series with the expansion wire is put back of the instrument proper. The heating effect is the same for continuous, pulsating or alternating currents of a given pressure so that this voltmeter is equally well adapted for any system.

The Cutler instruments are perfectly dead-beat, as it is impossible for the needle to move further than the expansion of the wire will permit. In other voltmeters the momentum of the moving part will carry it beyond the proper mark, after which it will vibrate for some little time. This annoying feature is avoided in the Cutler non-inductive voltmeter, in which the needle swings to the proper mark and stops there without any hesitation. For this reason a series of readings can be taken in very quick succession. These voltmeters are made with either a single or double scale to meet the varying requirements. Some built for storage battery work allow the needle to swing clear across the scale with less than three volts pressure, while those for street railway work range as high as 850 volts. Quite a number have been in use during the past year and the maker, George Cutter, of Chicago, is well pleased with the results. These voltmeters are licensed under the Cardew hot-wire patents.

THE CHICAGO ELECTRIC WIRE COMPANY.

THE insulated wires and cables made by the Chicago Insulated Wire Company, of Wilmington, Del., are having a very severe test. Seven cables were laid in the mud at the bottom of the Cristiana and Brandywine Rivers three years ago last month for the Wilmington Electric Light Company, and have all been in contant use without a single case of trouble ever since; they carry a current of 2,000 volts from a Westinghouse machine. The cables are No. 5, A. W. G. insulated with Chicago Electric Compound incased in a lead pipe and armored. The Wilmington City Electric Railway Company also have at the same place two 0000 A. W. G. cables of the same construction, and the Wilmington Water Department have just ordered five miles. This company are the successors of the Cobb Vulcanite Wire Company, but have gone into the business on a far greater scale, making everything in the insulated wire line. It is the intention of the company to spare no expense in its efforts to make this not only the largest but the leading insulated wire company, and also in the near future to build a plant in Chicago to supply the large and increasing demand.

THE SHULTZ BELTING COMPANY.

THE 1892 catalogue of the Shultz Belting Company, of St. Louis, Mo., has gone into its fifth edition. It is a most useful little book to all power users and contains much condensed information on the selection and management of machine belting, together with tables for the determination of the width of belts, horse power, etc.

THE JONES BROTHERS ELECTRIC COMPANY.

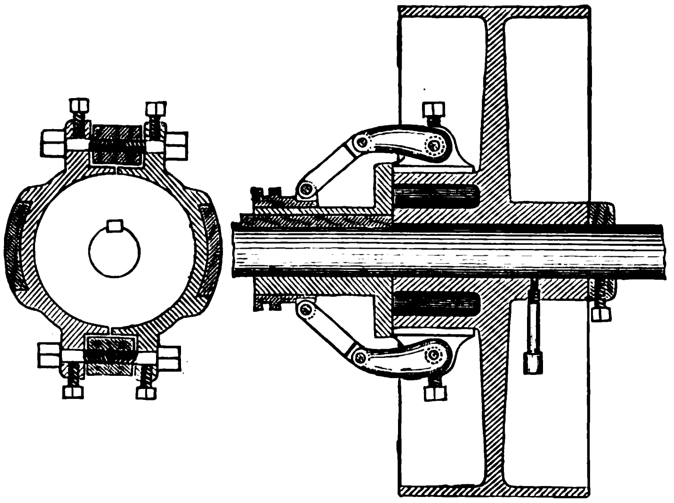
THE general electric supplies handled by the Jones Brothers Electric Company, of 28-32 West Court street, Cincinnati, Ohio, are well set forth in a catalogue of 345 pages issued by them, and containing descriptions and illustrations of apparatus covering the electrical field in a very thorough manner. The company are agents for the Perkins lamps and the Mather dynamos and motors.

BARNES FRICTION CLUTCH PULLEYS.

THE accompanying illustrations represent the principles of a friction clutch pulley and cut-off coupling manufactured by the J. H. & D. Lake Company, of Hornellsville, N. Y.

Fig. 1 affords a sectional side view of the Barnes screw lever friction pulley in released position, showing the driving hub keyed to the shaft.

Fig. 2 is a sectional end view showing the friction hub encircled by the friction ring, the former of which is cast in one solid piece with the pulleys. Projecting lugs on opposite sides of the driving hub of the ring drop into lug cavities of the friction ring; and when the clutch is on, these lugs take all the driving power. At the extreme top and bottom of Fig. 2 is shown a view of a simple device which evades the use of much complicated machinery and more than substitutes the corresponding complex parts of some previous inventions. It is a lever nut on each side of the friction ring, one-half of the nut being cut with a right thread and the other half with a left thread. Sufficient space between opposite sections of the ring is given for contraction or clutch, which is effected by means of right and left thread screw bolts entering the lever nut from opposite sides, secured by set screws. Duplex levers are attached to these nuts at their upper sections and to the hub at their lower sections. When the shipper sleeve is thrown against the flange by the operating lever, the duplex lever turns the nut sufficiently to produce a friction that is claimed to have never been known to lose its grip. The screw bolts are adjustable to any desired pressure, however, in case the clutch should ever become lax. They give the pulley a positive grip and absolute release from the hub by each opposite shift of the operating lever, without the use of springs. The Barnes screw lever friction clutch pulleys and cut-off couplings are adapted to both heavy and light work.



BARNES FRICTION CLUTCH PULLEY.

BALTIMORE NOTES.

THE GENERAL ELECTRIC COMPANY have just started up the blower plant in the Baltimore and Potomac Tunnel. Vast volumes of smoke are ejected from the high stack at the corner of Wilson and Madison avenues.

THE BRUSH ELECTRIC LIGHT COMPANY is just installing a 250 h. p. coil boiler, as the old boiler plant has been taxed to the utmost by the increased load this Fall.

H. K. MCCAY, electrical engineer and contractor, has just installed 200 lights for the William Knabe Piano Factory in South Baltimore.

THE BALTIMORE TRACTION COMPANY are all ready to begin operation on the Cary Street Electric Line, but are compelled to wait on a curve, which has been delayed by labor troubles in Pennsylvania.

LAUREL, MD., will be lighted by seventy incandescent lights, Work will begin at once.

WESTERN NOTES.

The Railway Equipment Company, Chicago, report a very large business in the Ahearn electric heaters. Orders for car heaters have been received from Amsterdam, N. Y.; Peoria, Ill.; Williamsport, Pa.; Kokomo, Ind.; Great Falls, Mont.; Camden, N. J.; Jackson, Mich.; Albany, N. Y.; Lynn, Mass.: Burlington, Iowa; Fitchburg, Mass.; Cairo, Ill.; Des Moines, Iowa; Allentown, Pa.; Rockford, Ill ; Cleveland, O.; Detroit, Mich.; Brooklyn, N. Y.; Spokane Falls, Wash.; Alexandria Va.; Kansas City, Mo ; Quincy, Mass.; Salt Lake City, Utah; Chicago; Natick, Mass.; Terre Haute, Ind.; Marquette, Mich.; Elwood, Pa.; Escanaba, Mich.; Kankakee, Ill.; New Haven, Conn ; Galesburg, Ill.; Hammond, Ind.; and large orders have also been received for the Ahearn electric stoves and other devices.

Mr. A. H. Atwood, who was formerly a large manufacturer in the east, has started a most complete plant here for the manufacture of carriage lamps, electric specialties and electric arc lamps for all systems of lighting. He is located at 166-174 South Clinton street, and has equipped his shop with all the latest and improved machinery for the economical production of goods, and will undoubtedly do a large business. Mr. Atwood has had a long and extensive experience in this class of business and is amply qualified to build up a very large trade throughout the west. He intends to use only the best material in everything put out, and the workmanship will also be first-class.

The Electric Appliance Company, of Chicago, are placing on the market an improved ceiling rosette in the line of an improvement on the Shaefer cut-out with a removable cap. The cap is attached without screws by a quarter turn to the right and detached by a similar turn in the opposite direction. To prevent the possibility of the cap jarring loose, which has been the great difficulty in other cut-outs of this style, a supplementary phosphor bronze spring has been added, making loosening almost an impossibility. The cut-out is placed on the market under the name of the "Acme Ceiling Cut-Out."

The merits of the Burton Electric Car Heaters were fully exemplified during the recent cold snap in the West. The heaters rendered cars in which they were used comfortably warm, without taking an excessive quantity of current. Mr. W. R. Daum, president of the Ottumwa Electric Road, speaking on this subject, said : "The fact that we commenced using the heaters three seasons ago and have continued to use them, buying four more sets for four new cars put on this fall, is best evidence possible of the work they have done and are doing for us."

The Pioneer Armature Works, room 415, 195 to 199 South Canal street, Chicago, are making a specialty of rewinding fields and armatures, renovating commutators and making other repairs on electrical machinery. They make an exclusive business of this line, and are prepared to guarantee good work at the best prices. They also make a special point of getting their work done with the utmost despatch. Immediately an armature or other piece of machinery is received it is repaired, and in this way they have acquired quite a reputation.

The Enterprise Electric Company, of 313 & 315 Dearborn street, Chicago, report a large increase in the sale of National India Rubber covered wire. Other electrical supplies are in great demand, and the company has been rushed since moving into its new quarters. It is about to put on the market a new flush switch, for which it has the exclusive agency. The St. Louis branch, W. H. Ferris, manager, reports a good and growing trade.

The Diamond Transformer.—Taylor, Goodhue & Ames, 827 Monadnock Building, Chicago, have closed a contract with the manufacturers for the entire output of the factory, and are preparing to properly introduce the transformer to central station managers. The "Diamond" possesses merit which will insure for it a high place in the opinion of practical men—it is said to be a record breaker.

The Charles F. Elmes Engineering Works will move during next January to their new works, corner of Morgan and Fulton streets, where they will install a large amount of new and improved machinery and have facilities for handling larger work than heretofore. Among other tools which they will install are a 20-ton traveling crane and a 10-inch boring and turning mill.

Mr. J. F. Kester, who is well known in electrical circles in the west, resigned from the Kester Arc Lamp and Manufacturing Company, of Ironwood, Mich., a short time ago, and associated himself with Mr. A. H. Atwood. They will design and bring out several important pieces of electrical apparatus.

Mr. W. J. Browne, secretary of the United States Electric Light and Power Company, of Dubuque, Iowa, was a Chicago visitor last week, looking after the purchase of additional machinery for his plant.

The Rice Machinery Company have a large number of contracts under way. Their business is very steady with electrical people and continually increasing.

Mr. Fred De Land's new paper, *World's Fair Electrical Engineering*, offers $175 in prizes for the best short essays on "How Can the Department of Electricity at the World's Fair Best Help the Electrical Interests?" The contest is open to all, and the essays must be in by January 14.

The Central Electric Company have just taken the agency for a combination tin shade, both flat and cone shaped. These shades are made under the patent granted to F. H. Soden, and will be known as the "Central Combination Shades." The trade can have their wants supplied by applying to the Central Electric Company, who will carry them in stock hereafter.

Mr. F. B. H. Pain, who was formerly connected with both the General Electric and Westinghouse companies, has joined the force of the Siemens-Halske Electric Company as assistant Mr. Amiel Meysenburg, of O. N. Meysenburg & Co., the St. Louis agents of the company.

Mr. W. W. Splane, superintendent of telegraph of the National Transit Company, with headquarters at Oil City, Pa., is spending a few days in Chicago. Mr. Splane is also filling the capacity of electrician to the Standard Oil Company.

The Columbia Manufacturing and Supply Company, Mr. John T. Todd manager, are bringing out a number of novel electrical devices, among others an electric cigar lighter and a new dry battery called the "Jupiter."

The Great Western Electric Supply Company are keeping up the volume of their business, and trade is very brisk with them, both in general electric supplies and the various specialties they manufacture and handle.

Mr. S. Dana Greene, assistant general manager of the General Electric Company, spent some days in Chicago recently.

The Siemens-Halske Electric Company are making rapid progress in the completion of their large factory.

Mr. Charles D. Shain, of New York, was among the visitors to the World's Fair City last week.

NEW YORK NOTES.

W. R. Fleming & Co.—The rapidly increasing business of this firm in Central and New England States, has made it necessary for them to open a branch office in Boston to look after that trade. They have obtained offices in the Hathaway Building, 620 Atlantic avenue, and have secured the services of Mr. Walter W. Jones, as manager. Mr. Jones is a man of long experience in the highest grades of steam engineering work, and is well known throughout the New England States. He has already secured several contracts and has other large work in hand. Since the reorganization and re-equipment of the Harrisburg Foundry and Machine Works, the class of work turned out as shown in both simple and compound Ide and Ideal engines compares with the best engineering work of similar lines. There has been almost constant work day and night to keep up with increasing orders and contracts, and further extension of plant is contemplated to take care of present and prepare for future work.

Mr. Willard W. Low, president of the Electric Appliance Company, Chicago, was a visitor in New York the past week. He spent several days in the city in search of novelties, in the way of electrical supplies generally. Mr. Low visited while in the East all the large cities, calling on most of the important manufacturers. Some desirable connections have been made, and there is reason to believe that the Electric Appliance Company will "be heard from" after the first of the year.

Lieb Machine Works.—All communications regarding, and orders for, railway line material manufactured by the Lieb Machine Works, should now be addressed to the General Electric Company; full arrangements having been made to this effect.

Mr. F. S. Terry, of the Electrical Supply Company, Chicago, has been a visitor to the East during the past week or two, and while in New York favored the office of **The Electrical Engineer** with a call.

The Caldwell Boiler Company, 15 Cortland street, N. Y., has been awarded the contract for supplying 600 h. p. of boilers in the Metropolitan Realty Company's new fourteen story building.

The Berlin Iron Bridge Company, of East Berlin, Conn., have the contract for three new iron buildings and iron roofs for the East River Gas Company, to be built at Ravenswood, L. I.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.
